

Ultra Low Power 1-Bit 32 kHz RTC

Features

- Supply current typically 390 nA at 3 V
- 50 ns access time with 50 pF load capacitance
- Fully operational from 1.2 V to 5.5 V
- No busy states or danger of a clock update while accessing
- Serial communication on one line of a standard parallel data bus or over a conventional 3 wire serial interface
- Interface compatible with both Intel and Motorola
- Seconds, minutes, hours, day of month, month, year, week day and week number in BCD format
- Leap year and week number correction
- Time set lock mode to prevent unauthorized setting of the current time or date
- Oscillator stability 0.3 ppm / volt
- No external capacitor needed
- Frequency measurement and test modes
- Temperature range -40 to +85°C
- On request extended temperature range, -40 to +125°C
- Pin compatible with the V 3021
- TSSO8 and SO8 packages

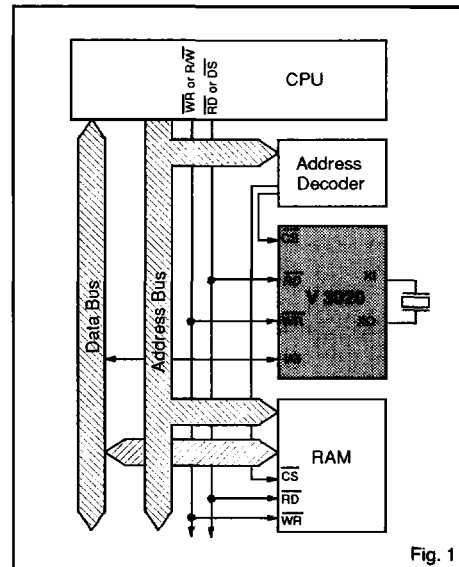

Description

The V 3020 is a low power CMOS real time clock. Data is transmitted serially as 4 address bits and 8 data bits, over one line of a standard parallel data bus. The device is accessed by chip select (\overline{CS}) with read and write control timing provided by either \overline{RD} and \overline{WR} pulse (Intel CPU) or \overline{DS} with advanced $\overline{R/W}$ (Motorola CPU). Data can also be transmitted over a conventional 3 wire serial interface having CLK, data I/O and strobe. The V 3020 has no busy states and there is no danger of a clock update while accessing. Supply current is typically 390 nA at $V_{DD} = 3.0$ V. Battery operation is supported by complete functionality down to 1.2 V. The oscillator stability is typically 0.3 ppm/V.

Applications

- Utility meters
- Battery operated and portable equipment
- Consumer electronics
- White/brown goods
- Pay phones
- Cash registers
- Personal computers
- Programmable controller systems
- Data loggers
- Automotive systems

Pin Assignment

Absolute Maximum Ratings

Parameter	Symbol	Conditions
Maximum voltage at V_{DD}	V_{DDmax}	$V_{SS} + 7.0V$
Minimum voltage at V_{DD}	V_{DDmin}	$V_{SS} - 0.3V$
Maximum voltage at any signal pin	V_{max}	$V_{DD} + 0.3V$
Minimum voltage at any signal pin	V_{min}	$V_{SS} - 0.3V$
Maximum storage temperature	T_{STOmax}	+150°C
Minimum storage temperature	T_{STOmin}	-65°C
Electrostatic discharge maximum to MIL-STD-883C method 3015	V_{Smax}	1000V
Maximum soldering conditions	T_{Smax}	250°C x 10 s

Table 1

Stresses above these listed maximum ratings may cause permanent damage to the device. Exposure beyond specified operating conditions may affect device reliability or cause malfunction.

Handling Procedures

This device has built-in protection against high static voltages or electric fields; however, it is advised that nor-

mal precautions be taken as for any other CMOS component. Unless otherwise specified, proper operation can only occur when all terminal voltages are kept within the supply voltage range. Unused inputs must always be tied to a defined logic voltage level.

Operating Conditions

Parameter	Symbol	Min.	Typ.	Max.	Units
Operating temperature ¹⁾	T_A	-40		+125	°C
Logic supply voltage	V_{DD}	1.2	5.0	5.5	V
Supply voltage dv/dt (power-up & power-down)				6	V/ μ s
Decoupling capacitor			100		nF

Table 3

The V 3020 will run slightly too fast, in order to allow the user to adjust the frequency, depending on the mean operating temperature. This is made since the crystal adjustment can only work by lowering the frequency with an added capacitor between XO and V_{SS}. The printed

circuit capacitance has also to be taken in consideration. The V 3020 in DIL 8 package, running with an 8.2 pF crystal at room temperature, will be adjusted to better than ± 1 s/day with a 6.8 pF capacitor.

Pin Description

Pin		Name	Function
SO8	TSSOP8		
1	3	XI	32 kHz crystal input
2	4	XO	32 kHz crystal output
3	5	CS	Chip select input
4	6	V _{SS}	Ground supply
5	7	I/O	Data input and output
6	8	RD	Intel RD, Motorola DS (or tie to CS)
7	1	WR	Intel WR, Motorola R/W
8	2	V _{DD}	Positive supply

Table 5

Functional Description

Serial Communication

The V 3020 resides on the parallel data and address buses as a standard peripheral (see Fig. 15 and 16). Address decoding provides an active low chip select (\overline{CS}) to the device. For Intel compatible bus timing the control signals RD and WR pulse and \overline{CS} are used for a single bit read or write (see Fig. 7a and 7b). Two options exist for Motorola compatible bus timing. The first is to use the control signals DS with R/W and CS, the second is to tie the RD input to CS and use the control signals R/W and CS (see Fig. 7a and 7c). Data transfer is accomplished through a single input/output line (I/O). Any data bus line can be chosen. A conventional 3 wire serial interface can also be used to communicate with the V 3020 (see Fig. 17).

Communication Cycles

The V 3020 has 3 serial communication cycles. These are:

- 1) Read data cycle
- 2) Write data cycle
- 3) Address command cycle

A communication cycle always begins by writing the 4 address bits, A0 to A3. A microprocessor read from the V 3020 cannot begin a communication cycle. Read and write data cycles are similar and consist of 4 address bits and 8 data bits. The 4 address bits, A0 to A3, define the RAM location and the 8 data bits, D0 to D7, provide the relevant information. An address command cycle consists of only 4 address bits.

Read Data Cycle

A read data cycle commences by writing the 4 RAM address bits (A3, A2, A1 and A0) to the V 3020. The LSB, A0, is transmitted first (see Fig. 8a and 8b). Eight microprocessor reads from the V 3020 will read the RAM data at this address, beginning with the LSB, D0. The read data cycle finishes on reading the 8th data bit, D7.

Write Data Cycle

A write data cycle commences by writing the 4 RAM address bits (A3, A2, A1 and A0) to the V 3020. The LSB, A0, is transmitted first (see Fig. 8c and 8d). Eight microprocessor writes to the V 3020 will write the new RAM data. The LSB, D0, is loaded first. The write data cycle finishes on writing the 8th data bit, D7.

Address Command Cycle

An address command cycle consists of just 4 address bits. The LSB, A0, is transmitted first (see Fig. 8e and 8f). On writing the fourth address bit, A3, the address will be decoded. If the address bits are recognized as one of the command codes E hex, or F hex (see Table 6), then the communication cycle is terminated and the corresponding command is executed. Subsequent microprocessor writes to the V 3020 begin another communication cycle with the first bit being interpreted as the address LSB, A0.

Clock Configuration

The V 3020 has a reserved clock area and a user RAM area (see Fig. 9). The clock is not directly accessible, it is used for internal time keeping and contains the current time and date. The contents of the RAM is shown in Table 6, it contains a data space and an address command space. The data space is directly accessible. Addresses 0 and 1 contain status information (see Tables 7a and 7b), addresses 2 to 5, time data, and addresses 6 to 9, date data. The address command space is used to issue commands to the V 3020.

RAM Map

Address		Parameter	BCD range
Dec	Hex		
Data Space			
0	0	Status 0	
1	1	Status 1	
2	2	Seconds	00-59
3	3	Minutes	00-59
4	4	Hours	00-23
5	5	Day of month	01-31
6	6	Month	01-12
7	7	Year	00-99
8	8	Week day	01-07
9	9	Week number	00-52
Address Command Space			
14	E	Copy_RAM_to_clock	
15	F	Copy_clock_to_RAM	

Table 6

Commands

Two commands are available (see Table 6). The Copy_RAM_to_clock command is used to set the current time and date in the clock and the Copy_clock_to_RAM command to copy the current time and date from the clock to the RAM. The Copy_RAM_to_clock command, address data E hex, causes the clock time and date to be overwritten by the time and date stored in the RAM at addresses 2 to 9. Address 1 is also cleared (see section "Time and Date Status Bits"). Prior to using this command, the desired time and date must be loaded into the RAM using write data cycles and the time set lock bit, address 0, bit 7, must be clear (see section "Time Set Lock").

Status Information

The RAM addresses 0 and 1 contain status and control data for the V 3020. The function of each bit (0 to 7) within address locations 0 and 1 is shown in Tables 7a and 7b respectively.

Status Word

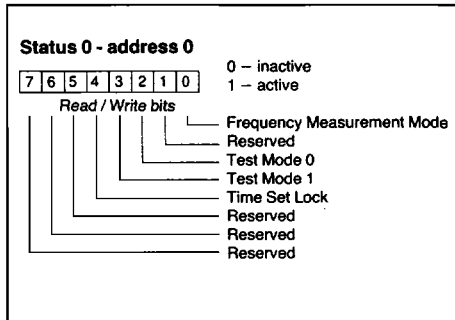

Table 7a

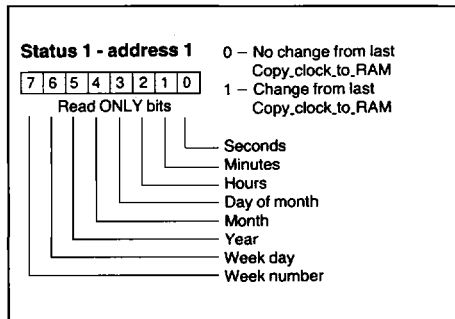

Table 7b

Reset and Initialization

Upon microprocessor recovery from a system reset, the V 3020 must be initialized by software in order to guarantee that it is expecting a communication cycle (i.e. the internal serial buffer is waiting for the address bit A0). Software can initialize the V 3020 to expect a communication cycle by executing 8 microprocessor reads (see Fig. 10).

Initializing Access to the V 3020

Fig. 10

On first startup or whenever power has failed ($V_{DD} < 1.2V$) the status register 0 and the clock must be initialized by software. Having initialized the interface to expect the address bit A0, write 0 to status register 0, then set the clock (see section "Clock and Calendar").

Time and Date Status Bits

There are time and date status bits at address 1 in the RAM. Upon executing a Copy_clock_to_RAM command, the time and date status bits in the RAM show which time and date parameters changed since the last time this command was used. A logic 1 in the seconds status bit (address 1, bit 0) in the RAM indicates that the seconds location in the RAM (address 2) changed since the last Copy_clock_to_RAM command and thus needs to be read. The seconds location must change before any other time or date location can change. If the seconds status bit is clear, then no time or date location changed since the last Copy_clock_to_RAM command and so the RAM need not be read by software.

Table 7b shows the seconds, minutes, hours, day of month, month, year, week day, and week number status bit locations. They are set or cleared similar to the seconds location. It should be noted that if the minutes status bit is clear, then the seconds bit may be set, but all other status bits are clear. Similarly with hours, the bits representing the units less than hours may have been set, but the bits for the higher units will be clear. This rule holds true for the week day or day of month locations also.

The time and date status bits can be used to drive software routines which need to be executed every

- second,
 - minute,
 - hour,
 - day of month / week day,
 - month,
 - year,
- or
- week.

In this application it is necessary to poll the V 3020 at least once every time interval used as it does not generate an interrupt. Upon executing a Copy_RAM_to_clock command, the time and date status bits in the RAM are cleared.

Time Set Lock

The time set lock control bit is located at address 0, bit 4 (see Table 7a). When set by software, the bit disables the Copy_RAM_to_clock command (see section "Commands".) A set bit prevents unauthorized overwriting of the current time and date in the clock. Clearing the time set lock bit by software will re-enable the Copy_RAM_to_clock command. On first startup or whenever power has failed ($V_{DD} < 1.2V$), the time set lock bit must be setup by software.

Reading the Current Time and Date

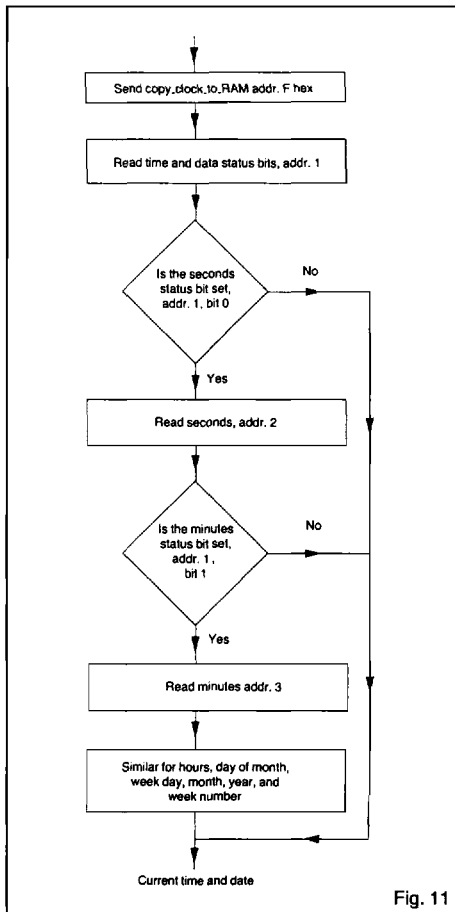

Fig. 11

Clock and Calendar

The time and date addresses in the RAM (see Table 6) provide access to the seconds, minutes, hours, day of month, month, year, week day, and week number. These parameters have the ranges indicated on Table 6 and are in BCD format. If a parameter is found to be out of range, it will be cleared on its being next incremented. The V 3020 incorporates leap year correction and week number calculation. The week number changes only at the incrementation of the day number from 7 to 1. If week 52 day 7 falls on the 25th, 26th or 27th of December, then the week number will change to 0 otherwise it will be week 1. Week days are numbered from 1 to 7 with Monday as 1.

Reading of the current time and date must be preceded

by a Copy_clock_to_RAM command. The time and date status bits will indicate which time and date addresses changed since the last time the command was used (see Fig. 11). The time and date from the last Copy_clock_to_RAM command is held unchanged in the RAM, except when power (V_{DD}) has failed totally. To change the current time and date in the clock, the desired time and date must first be written to the RAM, the time set lock bit cleared, and then a Copy_RAM_to_clock command sent (see Fig. 12). The time set lock bit can be used to prevent unauthorized setting of the clock.

Setting the Current Time and Date

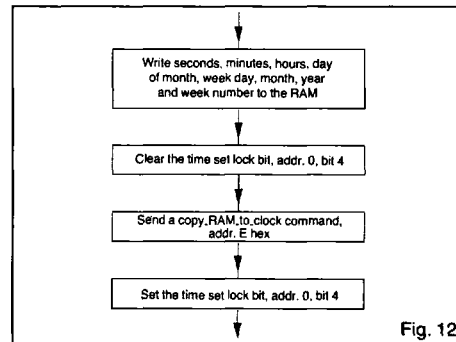

Fig. 12

4

Frequency Measurement

Setting bit 0 at address 0 will put a pulsed current source ($25 \mu A$) onto the I/O pin, when the device is not chip selected (i.e. CS input high). The current source will be pulsed on/off at 256 Hz. The period for ± 0 ppm time keeping is 3.90625 ms. To measure the frequency signal on pin I/O, the data bus must be high impedance. The best way to ensure this is to hold the microprocessor and peripherals in reset mode while measuring the frequency. The clarity of the signal measured at pin I/O will depend on both the probe input impedance (typically $1 M\Omega$) and the magnitude of the leakage current from other devices driving the line connected to pin I/O. If the signal measured is unclear, put a $200 k\Omega$ resistor from pin I/O to V_{SS} . It should be noted that the magnitude of the current source ($25 \mu A$) is not sufficient to drive the data bus line in case of any other device driving the line, but it is sufficient to take the line to a high logic level when the data bus is in high impedance.

Use a crystal of nominal $C_L = 8.2 pF$ as specified in the section "Operating Conditions". The MX series from Microcrystal is recommended. The accuracy of the time keeping is dependent upon the frequency tolerance and the load capacitance of the crystal. 11.57 ppm corresponds to one second a day.

Test

From the various test features added to the V 3020 some may be activated by the user. Table 7a shows the test mode bits. Table 8 shows the 3 available test modes and how they can be activated. Test mode 0 is activated by setting bit 2, address 0, and causes all time keeping to be accelerated by 32. Test mode 1 is activated by setting bit 3, address 0, and causes all the time and date locations, address 2 to address 9, to be incremented in parallel at 1 Hz with no carry over (independent of each other). The third test mode combines the previous two resulting in parallel incrementing at 32 Hz.

Test Modes

Addr. 0 bit 3	Addr. 0 bit 2	Function
0	0	Normal operation
0	1	All time keeping accelerated by 32
1	0	Parallel increment of all time data at 1 Hz with no carry over
1	1	Parallel increment of all time data at 32 Hz with no carry over

Table 8

An external signal generator can be used to drive the divider chain of the V 3020. Fig. 13a and 13b shows how to connect the signal generator. The speed can be increased by increasing the signal generator frequency to a maximum of 128 kHz. An external signal generator and test modes can be combined.

To leave test both test bits (address 0, bits 2 and 3) must be cleared by software. Test corrupts the current time and date and so the time and date should be reloaded after a test session.

Signal Generator Connection

Fig. 13a

Note: The peak value of the signal provided by the signal generator should not exceed 1.5 V on XO.

Fig. 13b

Note: The peak value of the signal provided by the signal generator should not exceed 1.5 V on XO.

Crystal Layout

In order to ensure proper oscillator operation we recommend the following standard practices:

- Keep traces as short as possible.
- Use a guard ring around the crystal.

Fig. 12 shows the recommended layout.

Oscillator Layout

Fig. 14

Access Considerations

The section "Communication Cycles" describes the serial data sequences necessary to complete a communication cycle. In common with all serial peripherals, the serial data sequences are not re-entrant, thus a high priority interrupt, or another software task, should not attempt to access the V 3020 if it is already in the middle of a cycle. A semaphore (software flag) on access would allow the V 3020 to be shared with other software tasks or interrupt routines. There is not time limit on the duration of a communication cycle and thus interrupt routines (which do not use the V 3020) can be fully executed in mid cycle without any consequences for the V 3020.
