12-BIT ADDRESS COMPARATORS**

D2661, JUNE 1982 — REVISED MAY 1986

T-45-17

- 'ALS679 is a 12-Bit Address Comparator with Enable
- 'ALS680 is a 12-Bit Address Comparator with Latch
- Package Options Include "Small Outline" Packages, Ceramic Chip Carriers, and Standard Plastic and Ceramic 300-mil DIPs
- Dependable Texas Instruments Quality and Reliability

**description**

The 'ALS679 and 'ALS680 address comparators simplify addressing of memory boards and/or other peripheral devices. The four P inputs are normally hard wired with a preprogrammed address. An internal decoder determines what input information applied to the 12 A inputs must be low or high to cause a low state at the output (Y). For example, a positive-logic bit combination of 0111 (decimal 7) at the P input determines that inputs A1 through A7 must be low and that inputs A8 through A12 must be high to cause the output to go low. Equality of the address applied at the A inputs to the preprogrammed address is indicated by the output being low.

The 'ALS679 features an enable input ( $\bar{G}$ ). When  $\bar{G}$  is low, the device is enabled. When  $\bar{G}$  is high, the device is disabled and the output is high regardless of the A and P inputs. The 'ALS680 features a transparent latch and a latch enable input (C). When C is high, the device is in the transparent mode. When C is low, the previous logic state of Y is latched.

The SN54ALS679 and SN54ALS680 are characterized for operation over the full military temperature range of -55°C to 125°C. The SN74ALS679 and SN74ALS680 are characterized for operation from 0°C to 70°C.

NOTE 1: Load circuit and voltage waveforms are shown in Section 1.

TYPICAL APPLICATION INFORMATION

The 'ALS679 and 'ALS680 can be wired to recognize any one of  $2^{12}$  addresses. The number of "lows" in the address determines the input pattern for the P inputs. Then those system address lines that are low in the address to be recognized are connected to the lowest numbered A inputs of the address comparator and the system address lines that are high are connected to the highest numbered A inputs.

For example, assume the comparator is to enable a device when the 12-bit system address is:

A11 A10 A9 A8 A7 A6 A5 A4 A3 A2 A1 A0  
H H L L H H L L H H H H

Since the address contains 4 lows and 8 highs, the following connections are made:

P3 to 0 V, P2 to VCC, P1 to 0 V, and P0 to 0 V.

System address lines A9, A8, A5, and A4 to comparator inputs A1 through A4 in any convenient order.

The remaining eight system address lines to comparator inputs A5 through A12 in any convenient order.

The output provides an active-low enabling signal.

The following circuit is a register bank decoder that examines the 14 most significant bits (A0 through A13) of a 20-bit address to select banks corresponding to the hex addresses 10000, 10040, 10080, and 100C0.
