LED displays

●Block diagrams

(1) Memory Type (LUM-512HML300 is advertised in here for just memory type of an example)

(2) Shift register type (LUM-512HML320 is advertised in here for just shift register type of an example)

## LED displays

## ● Pin descriptions

## (1) CN-1

## 1) RDin

Data input for red LED. LED is on when this pin is HIGH, and off when it is LOW.

## 2) GRin

Data input for green LED. LED is on when this pin is HIGH, and off when it is LOW.

## 3) CLKin

Clock input. Used to load RDin and GRin data. Data is loaded into the internal shift register at the leading edge of the CLK signal.

## 4) A0in - A3(A4)in

RAM address input. This specifies the address in memory to which display data will be written.

## 5) WEin

Write control signal. When this signal is HIGH, the contents of the internal shift register are written to memory.

(Only valid when AEin is HIGH.)

## 6) AEin

Address control signal. When this signal is HIGH, the current address in A0in - A3(A4)in is specified.

## 7) A/BBin

Control signal for selecting memory where data will be written. When this signal is HIGH, ARAM is selected, and when it is LOW, BRAM is selected. (Only valid when SEin is HIGH.) The contents of the memory not selected for writing will be displayed.

## 8) SEin

This signal determines whether memory selection will be made by external control or internal control. When this signal is HIGH, the A/BBin signal determines whether ARAM or BRAM is selected. When ARAM is selected for writing, the BRAM data is displayed, and when BRAM is selected for writing, the ARAM data is displayed. When this signal is LOW, data will be written to a different memory (from address 0) after the last memory address (15 or 23) is written to. The display data will change simultaneously with the memory change.

## 9) ENBin

Display output is Enable. It becomes display state HIGH level, non-display state at Low level.

## (2) CN-2

## 1) RDout

Data output for red LED. The signal is output simultaneously with CLK after passing through internal bit shift register 16 (24, 32, 48). If LED modules are connected serially, this pin will be connected to the next module's RDin pin.

## 2) GRout

Data output for green LED. The signal is output simultaneously with CLK after passing through internal bit shift register 16 (24, 32, 48). If LED modules are connected serially, this pin will be connected to the next module's RDin pin.

## 3) CLKout

Clock signal output. This pin outputs the CLKin signal. The pin connects to the next module's CLKin pin.

## 4) A0out - A3(A4)out

Address signal output. These pins output the signals of A0in - A3(A4)in. The pins connect to the next module's A0in - A3(A4)in pins.

## 5) WEout

WE (write control) signal output. This pin outputs the WEin signal. The pin connects to the next module's WEin pin.

## 6) AEout

AE (address control) signal output. This pin outputs the AEin signal. The pin connects to the next module's AEin pin.

## 7) A/BBout

A/BB (selection of memory for writing) signal output. This pin outputs the A/BBout signal. The pin connects to the next module's A/BBin pin.

## 8) SEout

SE (memory selection control) signal output. This pin outputs the SEin signal. The pin connects to the next module's SEin pin.

## LED displays

## 9) ENBout

ENB signal output. The ENBin signal is outputted. It is connected to ENBin of the next module.

●Shift register type pin function specifications

## -CN1-

- CLKin Clock input. Used to load RDin and GRin data. Data is loaded into the internal shift register at the leading edge of the CLK signal.
- Redin Data input for red LED. LED is on when this pin is HIGH, and off when it is LOW.
- Gmin Data input for green LED. LED is on when this pin is HIGH, and off when it is LOW.
- LATCHin Inputs a display data latch signal. The data is latched at Low and put through at High.
- ENBin Inputs a display enable signal. The display turns OFF at High and turns ON at Low.
- A0~A3in Inputs a common selection address signal. Specifies the common address in which the display data is output.

	A0	A1	A2	A3
ACOM0	0	0	0	0
ACOM1	1	0	0	0
ACOM2	0	1	0	0
ACOM3	1	1	0	0
ACOM4	0	0	1	0
ACOM5	1	0	1	0
ACOM6	0	1	1	0
ACOM7	1	1	1	0
ACOM8	0	0	0	1
ACOM9	1	0	0	1
ACOM10	0	1	0	1
ACOM11	1	1	0	1
ACOM12	0	0	1	1
ACOM13	1	0	1	1
ACOM14	0	1	1	1
ACOM15	1	1	1	1

- GND Control circuit ground.

## -CN2-

- CLKout Clock signal output. This pin outputs the CLKin signal. The pin connects to the next module's CLKin pin.
- Redout Data output for red LED. The signal is output simultaneously with CLK after passing through internal bit shift register 16 (24, 32, 48). If LED modules are connected serially, this pin will be connected to the next module's RDin pin.
- Gmout Data output for green LED. The signal is output simultaneously with CLK after passing through internal bit shift register 16 (24, 32, 48). If LED modules are connected serially, this pin will be connected to the next module's GRin pin.
- LATCHout Outputs a display data latch signal. An LATCHin signal is output. Connect this to the next module's LATCHin.
- ENBout Outputs a display enable signal. An ENBin signal is output. Connect this to the next module's ENBin.
- A0~A3out Outputs a common selection address. An A0in~A3in signal is output. Connect this to the next module's A0in~A3in.
- GND Ground for the control circuit.

## LED displays

-CN3-

- GND Control circuit & ground for the LED.
- VLED Power supply for the LED.
- VDD Power supply for the control circuit.

(3) CN-3

- 1) GND  
Control circuit ground.
- 2) VLED  
Supply voltage for LED.
- 3) GNDLED  
LED ground
- 4) VDD  
Supply voltage for control circuit.

●Attention points in handling LED dot matrix units

- (1) Do not drop a dot matrix unit. This may cause deformation of the display or cracks in the solder.
- (2) Be sure to mount the unit in the correct direction. Otherwise, the flow of data will be reversed.

- (3) Excessive heat in the unit can cause a drop in luminosity and other operational problems. Use a fan or other means to ensure sufficient heat dissipation.
- (4) The current required for the power supply varies greatly depending on the frequency of turning the LED on. Use a stable power supply which has sufficient capacity to handle sudden changes in load.
- (5) When joining units together to form a panel, design the panel to allow sufficient overall heat dissipation and leave enough clearance for thermal expansion.  
(As a general guideline, leave a gap of 0.3 mm between units.)
- (6) Do not rub the display surface or use organic solvents such as thinner to clean the display surface.
- (7) These units use high density LSI circuits. Therefore, take sufficient measures to protect them from electrostatic discharge.
- (8) Do not short-circuit the units or apply unnecessarily high voltages to them.
- (9) Do not use the units in conditions where the circuits will be directly exposed to wind and rain.
- (10) If a unit is used at high frequency or if several units are connected together and the signal cable is long, noise may cause malfunctioning. In this case, use a shielded cable and terminate end components.
- (11) As time passes, a difference in luminance may develop between LEDs which illuminate frequently and LEDs which do not. This will be particularly apparent if certain LEDs remain constantly illuminated.
- (12) Ground the control circuit and LED close to the power supply equipment.

Note: This product may be classified as a strategic good (or function) determined by the foreign exchange and foreign trade laws. Therefore, when export this product, be sure to consult ROHM. This product is not designed for radiation resistance.

LED displays

●Timing diagram

(1) 16×16, 16×32 Memory type

The display data are fetched at the leading edge of the clock and are outputted at the following edge.  
 Data are not fetched when AEin is "H", and the previous data are kept outputted on the display.  
 The RAM is switched by A/BB (SEin = "H") or when the address F A0~A3 is hold and AEin goes down.  
 When RAM is switched by A/BB, it is done by (A) timing usually.  
 RAM switching timing changed over irrespective of display.  
 AEin is outputted while CLKin is "L".

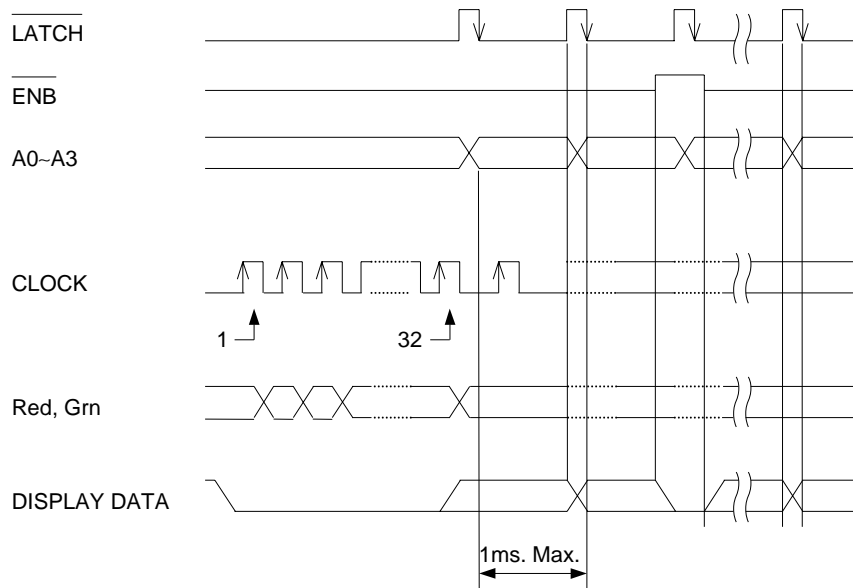

Parameter	Symbol	Min.	Typ.	Max.	Parameter	Symbol	Min.	Typ.	Max.
Clock frequency	f	—	—	20MHz	Address set-up time	t <sub>SA</sub>	15	—	—
Address enable holding time (1)	t <sub>WE1</sub>	10	—	—	Address hold time	t <sub>HA</sub>	15	—	—
Address enable holding time (2)	t <sub>WE2</sub>	10	—	—	Data set-up time	t <sub>SD</sub>	10	—	—
Write pulse time	t <sub>WP</sub>	30	—	—	Data hold time	t <sub>HD</sub>	10	—	—
RAM selection time (1)	t <sub>S1</sub>	15	—	—	Address enable set-up time	t <sub>SAE</sub>	10	—	—
RAM selection time (2)	t <sub>S2</sub>	15	—	—	Address enable hold time	t <sub>HAE</sub>	5	—	—

Controller unit input timing chart

LED displays

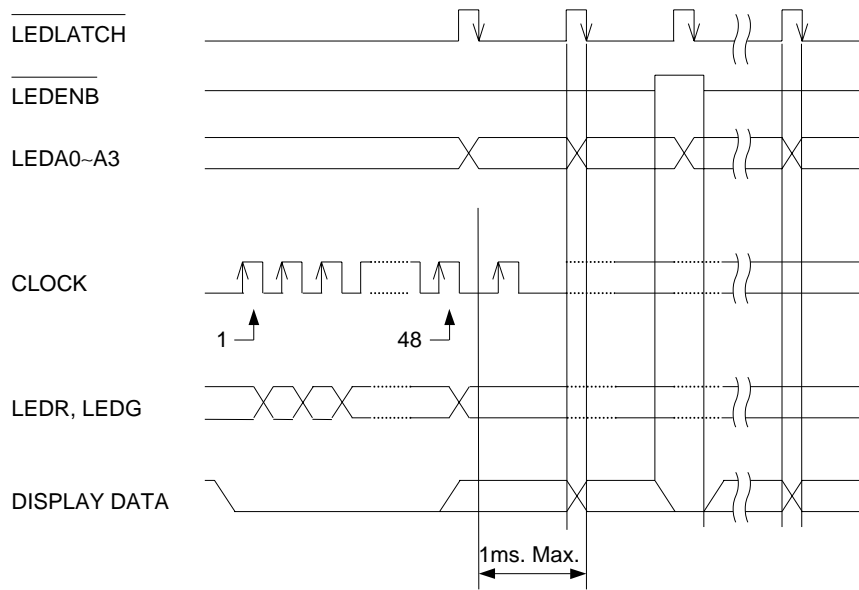

(2) 16×32 shift register type

\* If the value in the shift register changes while the LATCH signal status is "H", the latch data changes accordingly.

LED displays

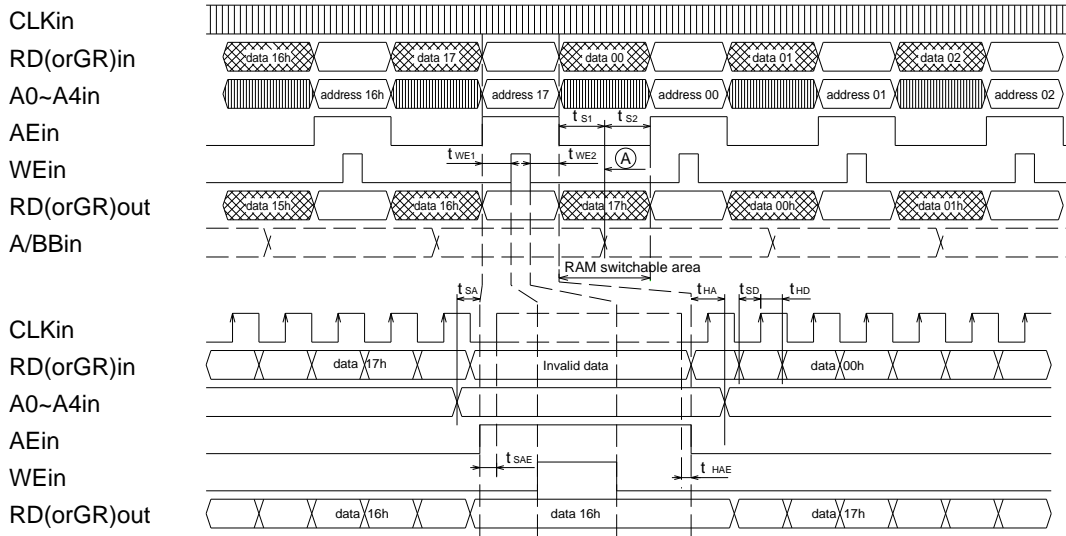

(3) 16×48 shift register type

\* If the value in the shift register changes while the LATCH signal status is "H" the latch data changes accordingly.

LED displays

(4) 24×24, 48×48 Memory type

The display data are fetched at the leading edge of the clock and are outputted at the following edge.  
 Data are not fetched when AEin is "H", and the previous data are kept outputted on the display.  
 Display data invalid when AE High.  
 The RAM is switched by A/BB (SEin = "H") or when the address A0~A4 is held at 17h and AEin is dropped.  
 RAM switching timing changed over irrespective of display.  
 When RAM is switched by A/BB, it is done by (A) timing usually.  
 AEin is outputted while CLKin is "L".  
 If AE is dropped during CLK is "H", shift register data are shifted one bit.
