CMOS IC

CAN TRANSCEIVER FOR 24V SYSTEMS

DESCRIPTION

The UTC **UCA82C251** is the interface between a CAN protocol controller and the physical bus. The device provides differential transmit capability to the bus and differential receive capability to the CAN controller. It is primarily intended for applications up to 1 MBd in trucks and buses.

FEATURES

- * Fully compatible with the "ISO 11898-24V" standard
- * Slope control to reduce Radio Frequency Interference (RFI)
- * Short-circuit proof to battery and ground in 24V powered systems
- * An unpowered node does not disturb the bus lines
- * Thermally protected
- * Low-current Standby mode
- * At least 110 nodes can be connected
- * High speed (up to 1 MBd)
- * High immunity against electromagnetic interference

■ FUNCTIONAL DESCRIPTION

The UTC **UCA82C251** is the interface between a CAN protocol controller and the physical bus. It is primarily intended for applications up to 1 MBd in trucks and buses. The device provides differential transmit capability to the bus and differential receive capability to the CAN controller. It is fully compatible with the "ISO 11898-24 V" standard.

A current-limiting circuit protects the transmitter output stage against short-circuits to positive and negative battery voltage. Although power dissipation will increase as a result of a short circuit fault condition, this feature will prevent destruction of the transmitter output stage.

If the junction temperature exceeds approximately 160°C, the limiting current of both transmitter outputs is decreased. Because the transmitter is responsible for most of the power dissipated, this will result in reduced power dissipation and hence a lower chip temperature. All other parts of the IC will remain operational. The thermal protection is needed, in particular, when a bus line is short-circuited.

The CANH and CANL lines are also protected against electrical transients which may occur in an automotive environment.

Pin 8 (Rs) allows three different modes of operation to be selected: High-speed, Slope control and Standby.

For high-speed operation, the transmitter output transistors are simply switched on and off as fast as possible. In this mode, no measures are taken to limit the rise and fall slopes. A shielded cable is recommended to avoid RFI problems. High-speed mode is selected by connecting pin 8 to ground.

Slope control mode allows the use of an unshielded twisted pair or a parallel pair of wires as bus lines. To reduce RFI, the rise and fall slopes should be limited. The rise and fall slopes can be programmed with a resistor connected from pin 8 to ground. The slope is proportional to the current output at pin 8.

If a HIGH level is applied to pin 8, the circuit enters a low-current Standby mode. In this mode, the transmitter is switched off and the receiver is switched to a low current. If dominant bits are detected (differential bus voltage >0.9 V), RXD will be switched to a LOW level. The microcontroller should react to this condition by switching the transceiver back to normal operation (via pin 8). Because the receiver is slower in Standby mode, the first message will be lost at higher bit rates.

Table 1. Truth table of the CAN transceiver

Supply	TXD	CANH	CANL	Bus state	RXD
4.5V to 5.5V	0	HIGH	LOW	dominant	0
4.5V to 5.5V	1 (or Floating)	Floating	Floating	Recessive	1 (Note 1)
4.5V <V _{CC} <5.5V	X (Note 2)	Floating If	Floating If	Floating	X (Note 1)
0V<V _{CC} < 4.5V	Floating	Floating	Floating	Floating	X (Note 2)

Notes: 1. If another bus node is transmitting a dominant bit, then RXD is logic 0.

2. X = don't care.

Table 2. Pin Rs summary

Condition Forced at Pin Rs	Mode	Resulting Voltage or Current at Pin Rs
$V_{Rs} > 0.75 \times V_{CC}$	Standby	$-I_{Rs} < 10\mu A$
$10\mu A < -I_{Rs} < 200\mu A$	Slope Control	$0.4V_{CC} < V_{Rs} < 0.6 \times V_{CC}$
$V_{Rs} < 0.3V_{CC}$	High-Speed	$-I_{Rs} < 500\mu A$
