Functional Description

CY62187G30 is a high-performance CMOS, low-power (MoBL®) SRAM device with embedded ECC^[2]. This device is offered in Dual Chip Enable option.

To access a Dual Chip Enable device, assert both Chip Enable inputs – \overline{CE}_1 as LOW and CE_2 as HIGH.

To perform data writes, assert the Write Enable (\overline{WE}) input LOW, and provide the data and address on the device data pins (I/O_0 through I/O_{15}) and address pins (A_0 through A_{21}) respectively. The Byte High Enable (\overline{BHE}) and Byte Low Enable (\overline{BLE}) inputs control byte writes and write data on the corresponding I/O lines to the memory location specified. \overline{BHE} controls I/O_8 through I/O_{15} and \overline{BLE} controls I/O_0 through I/O_7 .

To perform data reads, assert the Output Enable (\overline{OE}) input and provide the required address on the address lines. You can access the read data on the I/O lines (I/O_0 through I/O_{15}). To perform byte accesses, assert the required byte enable signal (\overline{BHE} or \overline{BLE}) to read either the upper byte or the lower byte of the data from the specified address location.

All I/Os (I/O_0 through I/O_{15}) are placed in a High-Z state when the device is deselected (\overline{CE}_1 HIGH / CE_2 LOW for a Dual Chip Enable device), or the control signals are deasserted (\overline{OE} , \overline{BLE} , \overline{BHE}).

These devices have a unique byte power-down feature where, when both Byte Enables (\overline{BHE} and \overline{BLE}) are disabled, the devices seamlessly switch to the standby mode irrespective of the state of the Chip Enables, thereby saving power.

CY62187G30 is available in a Pb-free 48-ball VFBGA package. See [Logic Block Diagram – CY62187G30 on page 2](#).

Figure 1. 48-ball VFBGA Pinout (Dual Chip Enable) – CY62187G30 ^[4]

Notes

- NC pins are not connected internally to the die and are typically used for address expansion to a higher-density device. Refer to the respective datasheets for pin configuration.
- Tie the $\overline{\text{BYTE}}$ pin in the 48-pin TSOP I package to V_{CC} to use the device as a 2M × 16 SRAM. The 48-pin TSOP I package can also be used as a 4M × 8 SRAM by tying the $\overline{\text{BYTE}}$ signal to V_{SS}. In the 4M × 8 configuration, pin 45 is the extra address line A21, while $\overline{\text{BHE}}$, $\overline{\text{BLE}}$, and I/O₈ to I/O₁₄ pins are not used and can be left floating.

Notes

12. Indicates the value for the center of distribution at 3.0 V, 25°C and not 100% tested.

14. I_{CCDR} is guaranteed only after the device is first powered up to $V_{CC(min)}$ and then brought down to V_{DR} .
15. These parameters are guaranteed by design and are not tested.
16. Full-device operation requires linear V_{CC} ramp from V_{DR} to $V_{CC(min)}$ $\geq 400\text{ }\mu\text{s}$ or stable at $V_{CC(min)}$ $\geq 400\text{ }\mu\text{s}$.
17. $\overline{BHE}.\overline{BLE}$ is the AND of both \overline{BHE} and \overline{BLE} . Deselect the chip by either disabling the chip enable signals or by disabling both \overline{BHE} and \overline{BLE} .

Notes

18. Test conditions assume signal transition time (rise/fall) of 3 ns or less, timing reference levels of 1.5 V (for $V_{CC} \geq 3$ V) and $V_{CC}/2$ (for $V_{CC} < 3$ V), and input pulse levels of 0 to 3 V (for $V_{CC} \geq 3$ V) and 0 to V_{CC} (for $V_{CC} < 3$ V). Test conditions for the read cycle use the output loading shown in [Figure 2 on page 6](#), unless specified otherwise.
19. At any temperature and voltage condition, t_{HZOE} is less than t_{LZCE} , t_{HZBE} is less than t_{LZBE} , t_{HZOE} is less than t_{LZOE} , and t_{HZWE} is less than t_{LZWE} for any device.
20. Tested initially and after any design or process changes that may affect these parameters.
21. t_{HZOE} , t_{HZCE} , t_{HZBE} , and t_{HZWE} transitions are measured when the outputs enter a high-impedance state.
22. These parameters are guaranteed by design and are not tested.
23. The internal write time of the memory is defined by the overlap of $\overline{WE} = V_{IL}$, $\overline{CE}_1 = V_{IL}$, \overline{BHE} or \overline{BLE} or both = V_{IL} , and $CE_2 = V_{IH}$. All signals must be ACTIVE to initiate a write and any of these signals can terminate a write by going INACTIVE. The data input setup and hold timing must refer to the edge of the signal that terminates the write.
24. The minimum write cycle pulse width for Write Cycle No. 1 (\overline{WE} Controlled, \overline{OE} LOW) should be equal to the sum of t_{HZWE} and t_{SD} .

Notes

25. The device is continuously selected. $\overline{OE} = V_{IL}$, $\overline{CE} = V_{IL}$, \overline{BHE} or \overline{BLE} , or both = V_{IL} .

All signals must be ACTIVE to initiate a write and any of these signals can terminate a write by going INACTIVE. The data input setup and hold timing must refer to the edge of the signal that terminates the write.

31. Data I/O is in the High-Z state if $\overline{\text{CE}} = V_{\text{IH}}$, or $\overline{\text{OE}} = V_{\text{IH}}$, or $\overline{\text{BHE}}$, and/or $\overline{\text{BLE}} = V_{\text{IH}}$.

32. During this period, the I/Os are in the output state. Do not apply input signals.

35. All signals must be ACTIVE to initiate a write. Any of these signals can terminate a write by going INACTIVE. The data input setup and hold timing must refer to the edge of the signal that terminates the write.

39. The internal write time of the memory is defined by the overlap of $\overline{\text{WE}} = V_{\text{IL}}$, $\overline{\text{CE}}_1 = V_{\text{IL}}$, $\overline{\text{BHE}}$ or $\overline{\text{BLE}}$ or both = V_{IL} , and $\text{CE}_2 = V_{\text{IH}}$.
