

# Intel® Ethernet Controller X550

## Datasheet

### Ethernet Networking Division (ND)

#### PRODUCT FEATURES

##### General

- Serial Flash interface
- Configurable LED operation for software or customizing OEM LED displays
- Device disable capability
- Package size - 25 mm x 25 mm (X550-BT2)
- Package size - 17 mm x 17 mm (X550-AT2)

##### Networking

- 10 GbE/1 GbE/100 Mb/s copper PHYs integrated on-chip
- Support for jumbo frames of up to 15.5 KB
- Flow control support: send/receive pause frames and receive FIFO thresholds
- Statistics for management and RMON
- 802.1q VLAN support
- TCP segmentation offload: up to 256 KB
- IPv6 support for IP/TCP and IP/UDP receive checksum offload
- Fragmented UDP checksum offload for packet reassembly
- Message Signaled Interrupts (MSI)
- Message Signaled Interrupts (MSI-X)
- Interrupt throttling control to limit maximum interrupt rate and improve CPU usage
- Flow Director (16 x 8 and 32 x 4)
- 128 transmit queues
- Receive packet split header
- Receive header replication
- Dynamic interrupt moderation
- TCP timer interrupts
- Relaxed ordering
- Support for 64 virtual machines per port (64 VMs x 2 queues)
- Support for Data Center Bridging (DCB); (802.1Qaz, 802.1Qbb, 802.1p)

##### Host Interface

- PCIe 3.0 Base Specification
- Bus width — x1, x4, x8
- 64-bit address support for systems using more than 4 GB of physical memory

##### MAC FUNCTIONS

- Descriptor ring management hardware for transmit and receive
- ACPI register set and power down functionality supporting D0 and D3 states
- A mechanism for delaying/reducing transmit interrupts
- Software-controlled global reset bit (resets everything except the configuration registers)
- Four Software-Definable Pins (SDP) per port
- Wake up
- IPv6 wake-up filters
- Configurable flexible filter (through NVM)
- LAN function disable capability
- Programmable memory transmit buffers (160 KB/port)
- Default configuration by NVM for all LEDs for pre-driver functionality

##### Manageability

- SR-IOV support
- Eight VLAN L2 filters
- 16 Flex L3 port filters
- Four Flexible TCO filters
- Four L3 address filters (IPv4)
- Advanced pass through-compatible management packet transmit/receive support
- SMBus interface to an external Manageability Controller (MC)
- NC-SI interface to an external MC
- Four L3 address filters (IPv6)
- Four L2 address filters

Revision 2.2  
July 2017  
333369-004

## 1.0 Introduction

---

### 1.1 Scope

This document describes the external architecture (including device operation, pin descriptions, register definitions, etc.) for the X550, a dual port 10GBASE-T Network Interface Controller.

This document is intended as a reference for logical design group, architecture validation, firmware development, software device driver developers, board designers, test engineers, or anyone else who might need specific technical or programming information about the X550.

### 1.2 Product Overview

The X550 is a derivative of the X540. Many features of its predecessor remain intact; however, some have been removed or modified as well as new features introduced.

The X550 includes two integrated 10GBASE-T copper Physical Layer Transceivers (PHYs). A standard MDIO interface, accessible to software via MAC control registers, is used to configure and monitor each PHY operation.

#### 1.2.1 System Configurations

The X550 is targeted for system configurations such as rack mounted, pedestal servers or workstations, where it can be implemented used as an add-on NIC or LAN on Motherboard (LOM), or purchased from Intel as a standard PCIe\* adapter card.

Figure 1-1. Typical Rack/Pedestal System Configuration

## 1.3 External Interfaces

Figure 1-2. X550 External Interfaces Diagram

## 1.3.1 PCIe Interface

The X550 supports PCIe v3.0 (2.5 GT/s, 5 GT/s or 8 GT/s). See [Section 2.2.1](#) for full pin description and [Section 12.4.5](#) for interface timing characteristics.

## 1.3.2 Network Interfaces

Two independent 10GBASE-T interfaces are used to connect the two X550 ports to external devices. Each 10GBASE-T interface can operate at any of the following speeds:

- 10 Gb/s, 10GBASE-T mode
- 5 Gb/s, NBASE-T mode
- 2.5 Gb/s, NBASE-T mode
- 1 Gb/s, 1000BASE-T mode
- 100 Mb/s, 100BASE-TX mode
- Refer to [Section 2.2.2](#) for full-pin descriptions. For the timing characteristics of those interfaces, refer to the relevant external specifications listed in [Section 12.4.6](#).

## 1.3.3 Serial Flash Interface

The X550 uses an external SPI serial interface to a Flash device, also referred to as Non-Volatile Memory (NVM). The X550 supports serial Flash devices with up to 4 MB of memory.

## 1.3.4 SMBus Interface

SMBus is an optional interface for pass-through and/or configuration traffic between an external Manageability Controller (MC) and the X550.

The X550's SMBus interface supports a standard SMBus, up to a frequency of 1 MHz. Refer to [Section 2.2.4](#) for full-pin descriptions and [Section 12.4.4.3](#) for timing characteristics of this interface.

## 1.3.5 NC-SI Interface

NC-SI is an optional interface for pass-through traffic to and from an MC. The X550 meets the NC-SI version 1.0.0 specification.

Refer to [Section 2.2.5](#) for the pin descriptions, and [Section 11.6](#) for NC-SI programming.

### 1.3.6 Software-Definable Pins (SDP) Interface (General-Purpose I/O)

The X550 has four SDP pins per port that can be used for miscellaneous hardware or software-controllable purposes. These pins can each be individually configured to act as either input or output pins. Via the SDP pins, the X550 can support IEEE1588 auxiliary device connections and other functionality. For more details on the SDPs see [Section 3.5](#) and the ESDP register ([Section 8.2.2.1.4](#)).

### 1.3.7 LED Interface

The X550 implements four output drivers intended for driving external LED circuits per port. Each of the four LED outputs can be individually configured to select the particular event, state, or activity, which is indicated on that output. In addition, each LED can be individually configured for output polarity as well as for blinking versus non-blinking (steady-state) indications.

The configuration for LED outputs is specified via the LEDCTL register (see [Section 8.2.2.1.10](#)). In addition, the hardware-default configuration for all LED outputs can be specified via an NVM field (see [Section 6.4.7.3](#)), thereby supporting LED displays configured to a particular OEM preference. For more details on the LEDs see [Section 3.6](#).

## 1.4 Feature Summary

[Table 1-1](#) to [Table 1-7](#) list the X550's features in comparison to previous dual-port 10 GbE Ethernet controllers.

**Table 1-1. Network Features**

| Feature                                                                     | 82599          | X540           | X550           |
|-----------------------------------------------------------------------------|----------------|----------------|----------------|
| Compliant with the 10 GbE and 1 GbE Ethernet/802.3ap (KX/KX4) specification | Y              | N              | N              |
| Compliant with the 10 GbE 802.3ap (KR) specification                        | Y              | N              | N              |
| Compliant with XFI/SFI interface                                            | Y              | N              | N              |
| Compliant with the 1000BASE-BX specification                                | Y              | N              | N              |
| Full-duplex operation at all supported speeds                               | Y              | Y              | Y              |
| Half-duplex at 100 Mb/s operation                                           | N              | N              | N              |
| 10 GbE/1 GbE/100 Mb/s copper PHYs integrated on-chip                        | N              | Y              | Y              |
| 802.3az Energy Efficient Ethernet (EEE) support                             | N              | N              | Y              |
| Support jumbo frames of up to 15.5 KB                                       | Y <sup>1</sup> | Y <sup>1</sup> | Y <sup>1</sup> |
| MDIO interface Clause 45                                                    | Y              | Y (internally) | Y (internally) |
| Flow Control support: Send/receive pause frames and receive Fifo thresholds | Y              | Y              | Y              |
| Statistics for Management and RMON                                          | Y              | Y              | Y              |
| 802.1q VLAN support                                                         | Y              | Y              | Y              |
| SerDes interface for external PHY connection or system interconnect         | Y              | N              | N              |

**Table 1-1. Network Features (Continued)**

| Feature         | 82599                          | X540 | X550 |
|-----------------|--------------------------------|------|------|
| SGMII interface | Y<br>(100 Mb/s and 1 GbE only) | N    | N    |
| Double VLAN     | Y                              | Y    | Y    |

1. All the products support full-size 15.5 KB jumbo packets while in a basic mode of operation. When DCB mode is enabled, or security engines enabled, or virtualization is enabled, or OS2BMC is enabled, then only 9.5 KB jumbo packets are supported. Packets to/from the MC longer than 2 KB are filtered out.

**Table 1-2. Host Interface Features**

| Feature                                                                    | 82599                     | X540                      | X550                                                            |
|----------------------------------------------------------------------------|---------------------------|---------------------------|-----------------------------------------------------------------|
| PCIe* version (Speed)                                                      | PCIe v2.0<br>(5/2.5 GT/s) | PCIe v2.1<br>(5/2.5 GT/s) | PCIe v3.0<br>(8/5/2.5 GT/s)                                     |
| Number of lanes                                                            | x1, x2, x4, x8            | x1, x2, x4, x8            | x1, x4<br>x8 (For X550-BT2,<br>x8 available in<br>Gen 1/2 only) |
| 64-bit address support for systems using more than 4 GB of physical memory | Y                         | Y                         | Y                                                               |
| Outstanding requests for Tx data buffers                                   | 16                        | 16                        | 16                                                              |
| Outstanding requests for Tx descriptors                                    | 8                         | 8                         | 8                                                               |
| Outstanding requests for Rx descriptors                                    | 8                         | 8                         | 8                                                               |
| Credits for P-H/P-D/NP-H/NP-D (shared for the two ports)                   | 16/16/4/4                 | 16/16/4/4                 | 16/16/4/4                                                       |
| Max Payload Size supported                                                 | 512 Bytes                 | 512 Bytes                 | 512 Bytes                                                       |
| Max Request Size supported                                                 | 2 KB                      | 2 KB                      | 2 KB                                                            |
| Link layer retry buffer size (shared for the two ports)                    | 3.4 KB                    | 3.4 KB                    | 3.4 KB                                                          |
| Vital Product Data (VPD)                                                   | Y                         | Y                         | Y                                                               |
| End to End CRC (ECRC)                                                      | Y                         | Y                         | Y                                                               |

| Device disable capability                                                    | Y     | Y    | Y    |

**Table 1-3. Miscellaneous Features (Continued)**

| Feature                 | 82599         | X540           | X550                           |
|-------------------------|---------------|----------------|--------------------------------|
| Package size            | 25 mm x 25 mm | 25 mm x 25 mm  | 25 mm x 25 mm<br>17 mm x 17 mm |
| Embedded thermal sensor | N             | Y              | Y                              |
| Embedded thermal diode  | N             | Y              | Y                              |
| Watchdog timer          | Y             | Y              | Y                              |
| Time Sync (IEEE 1588)   | Y             | Y <sup>1</sup> | Y                              |
| Time Stamp in packet    | N             | N              | Y                              |

1. Time sync not supported at 100 Mb/s link speed.

**Table 1-4. LAN Functions Features**

| Feature                                                                                                                     | 82599          | X540           | X550           |
|-----------------------------------------------------------------------------------------------------------------------------|----------------|----------------|----------------|
| Programmable host memory receive buffers                                                                                    | Y              | Y              | Y              |
| Descriptor ring management hardware for transmit and receive                                                                | Y              | Y              | Y              |
| ACPI register set and power down functionality supporting D0 and D3 states                                                  | Y              | Y              | Y              |
| Integrated IPsec security engines: AES-GCM 128-bit; AH or ESP encapsulation; IPv4 and IPv6 (no option or extension headers) | 1024 SA / port | 1024 SA / port | 1024 SA / port |
| Software-controlled global reset bit (resets everything except the PCIe configuration registers)                            | Y              | Y              | Y              |
| Software-Definable Pins (SDP) (per port)                                                                                    | 8              | 4              | 4              |
| Four SDP Pins can be configured as general purpose interrupts                                                               | Y              | Y              | Y              |
| Wake on LAN (WoL)                                                                                                           | Y              | Y              | Y              |
| IPv6 Wake-up Filters                                                                                                        | Y              | Y              | Y              |
| Configurable (through NVM) Wake-up Flexible Filters                                                                         | Y              | Y              | Y              |
| Default configuration by NVM for all LEDs for pre-driver functionality                                                      | Y              | Y              | Y              |
| LAN Function Disable capability                                                                                             | Y              | Y              | Y              |
| Programmable memory transmit buffers                                                                                        | 160 KB / port  | 160 KB / port  | 160 KB / port  |
| Programmable memory receive buffers                                                                                         | 512 KB / port  | 384 KB / port  | 384 KB / port  |

**Table 1-5. LAN Performance Features**

| Feature                                                                                                                                                                                                  | 82599                      | X540                       | X550                       |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------|----------------------------|----------------------------|
| TCP/UDP segmentation offload                                                                                                                                                                             | 256 KB in all modes        | 256 KB in all modes        | 256 KB in all modes        |
| TSO interleaving for reduced latency                                                                                                                                                                     | Y                          | Y                          | Y                          |
| TCP Receive Side Coalescing (RSC)                                                                                                                                                                        | 32 flows / port            | 32 flows / port            | 32 flows / port            |

| Traffic shaping                                                            | Y         | Y         | Y                    |
| Anti-spoof                                                                 | MAC, VLAN | MAC, VLAN | MAC, VLAN, Ethertype |
| Malicious driver protection                                                | N         | N         | Y                    |
| Forwarding modes                                                           | MAC, VLAN | MAC, VLAN | MAC, VLAN, E-tag     |

**Table 1-6. Virtualization Features (Continued)**

| Feature                                      | 82599 | X540 | X550 |
|----------------------------------------------|-------|------|------|
| VEB support                                  |       |      |      |
| • Multicast and broadcast packet replication | Y     | Y    | Y    |
| • Packet mirroring                           | Y     | Y    | Y    |
| • Packet loopback                            | Y     | Y    | Y    |
| VEPA support (on top of VEB support)         |       |      |      |
| • Source pruning                             | N     | N    | Y    |
| E-tag filtering support                      | N     | N    | Y    |

**Table 1-7. Manageability Features**

| Feature                                                                       | 82599 | X540             | X550 |
|-------------------------------------------------------------------------------|-------|------------------|------|
| Advanced pass-through-compatible management packet transmit/receive support   | Y     | Y                | Y    |
| SMBus interface to an external MC                                             | Y     | Y                | Y    |
| New Management Protocol Standards Support (NC-SI) interface to an external MC | Y     | Y                | Y    |
| L2 address filters                                                            | 4     | 4                | 4    |
| VLAN L2 filters                                                               | 8     | 8                | 8    |
| Flex L3 port filters                                                          | 16    | 16               | 16   |
| Flexible TCO filters                                                          | 4     | 4                | 1    |
| L3 address filters (IPv4)                                                     | 4     | 4                | 4    |
| L3 address filters (IPv6)                                                     | 4     | 4                | 4    |
| Host-based Application-to-BMC Network Communication patch (OS2BMC)            | N     | Y                | Y    |
| Flexible MAC Address                                                          | N     | Y                | Y    |
| MC inventory of LOM device information                                        | N     | Y                | Y    |
| iSCSI boot configuration parameters via MC                                    | N     | Y                | Y    |
| MC monitoring                                                                 | N     | Y                | Y    |
| NC-SI to iMC                                                                  | N     | Y                | Y    |
| NC-SI arbitration                                                             | N     | Y                | Y    |
| MCTP over SMBus (pass-through and control)                                    | N     | Y (control only) | Y    |
| MCTP over PCIe (pass-through and control)                                     | N     | N                | Y    |
| NC-SI package ID via SDP pins                                                 | N     | Y                | Y    |
| NC-SI Flow control                                                            | N     | N                | Y    |

## 1.5 Overview: New Capabilities Beyond the X540

### 1.5.1 NBASE-T Support

Support for 2.5GBASE-T and 5GBASE-T is added to the X550.

### 1.5.2 Filtering Capabilities

#### 1.5.2.1 Flow Director Improvements

Two new modes, based on cloud tenant ID or on MAC, VLAN are added to the X550 to allow support of the features described below. Also supported is a better definition of the packet which are candidate to the flow director filtering and the ability to drop candidate packets that do not match any filter.

#### 1.5.2.2 802.1BR Support

The X550 supports the IEEE 802.1BR specification. It allows forwarding to pools based on unicast or multicast E-tags and allow insertion and removal of the E-tag using a per pool policy.

To allow L2 filtering on top of the E-tag forwarding, the flow director may be configured to MAC, VLAN filtering and non matching packets may be dropped.

#### 1.5.2.3 VXLAN and NVGRE Support

The X550 supports detection and off-loading of NVGRE and VXLAN packets. It provides transmit and receive checksum off-load on both inner and outer IP headers and on TCP header. It also allows forwarding to a specific VM within a tenant using a new flow director mode.

In the regular IP mode of the flow director, VXLAN and NVGRE flows can be differentiated from regular IP packets and filtering based on the inner IP/L4 header is supported.

### 1.5.3 IEEE 1588 Improvements

The X550 improves the support for IEEE 1588 by adding the following features:

- Sampling based on a fixed clock, allowing operation independent from the link speed.
- Clock representation is divided to seconds, nanoseconds and sub-nano parts - allowing easier handling by software.
- Enabling of sub-ns periodic corrections.
- Gradual time adjustment of frequency corrections preventing single large correction. An interrupt is provided when the adjustment is done.
- Support for two different target times for SDP toggling.
- Each SDP can be associated with any 1588 functionality.
- Allow timestamp to be received in register or embedded in packet.

## 1.5.4 Manageability

### 1.5.4.1 DMTF MCTP Protocol Over PCIe

The X550 enables reporting and controlling all information exposed in a LOM device via NC-SI using the MCTP protocol over PCIe in addition to SMBus. The MCTP interface over PCIe is used by the MC to control the NIC and for pass-through traffic. In addition, the MCTP over SMBus interface can also be used for pass-through traffic. For more information, refer to [Section 11.7](#).

### 1.5.4.2 NVM Structures

Management related NVM structures were updated. For further information see [Section 6.0](#).

### 1.5.4.3 Simplified SMBus TCO Status and Filter Setting

The TCO status in an SMBus received packet was reduced to 8 bytes and most of the information was removed to keep only the information relevant to the MCs. See [Section 11.5.11.2.1.1](#) for details.

In addition, a generic command was added to enable the setting of most common filtering options independently of the actual filters implementation. See [Section 11.5.11.1.7](#) and [Section 11.5.11.1.8](#) for details.

### 1.5.4.4 Diagnostic Commands

A command was added to the legacy SMBus interface to enable querying the identity of the X550 and the firmware versions currently running on the X550. See [Section 11.5.11.2.6](#) for details. This command is the SMBus counterpart of the NC-SI command described in [Section 11.6.3.13.2](#).

## 1.6 Conventions

### 1.6.1 Terminology and Acronyms

See [Section 16.0](#), “Glossary and Acronyms”.

### 1.6.2 Byte Ordering

This section defines the organization of registers and memory transfers, as it relates to information carried over the network:

- Any register defined in Big Endian notation can be transferred as is to/from Tx and Rx buffers in the host memory. Big Endian notation is also referred to as being in network order or ordering.
- Any register defined in Little Endian notation must be swapped before it is transferred to/from Tx and Rx buffers in the host memory. Registers in Little Endian order are referred to being in host order or ordering.

Tx and Rx buffers are defined as being in network ordering; they are transferred as is over the network.

**Note:** Registers not transferred on the wire are defined in Little Endian notation. Registers transferred on the wire are defined in Big Endian notation, unless specified differently.

## 1.7 References

The X550 implements features from the following specifications:

### IEEE Specifications:

- 10GBASE-T as per the IEEE 802.3an standard.

## 1.8 Architecture and Basic Operation

### 1.8.1 Transmit (Tx) Data Flow

Tx data flow provides a high-level description of all data/control transformation steps needed for sending Ethernet packets over the wire.

**Table 1-8. Tx Data Flow**

| Step | Description                                                                                                                                                                                                                                                            |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1    | The software device driver creates a descriptor ring and configures one of the X550's transmit queues with the address location, length, head, and tail pointers of the ring (one of 128 available Tx queues).                                                         |
| 2    | The software device driver is requested by the TCP/IP stack to transmit a packet, it gets the packet data within one or more data buffers.                                                                                                                             |
| 3    | The software device driver initializes the descriptor(s) that point to the data buffer(s) and have additional control parameters that describes the needed hardware functionality. The host places that descriptor in the correct location in the appropriate Tx ring. |
| 4    | The software device driver updates the appropriate Queue Tail Pointer (TDT).                                                                                                                                                                                           |
| 5    | The X550's DMA senses a change of a specific TDT and as a result sends a PCIe request to fetch the descriptor(s) from host memory.                                                                                                                                     |
| 6    | The descriptor(s) content is received in a PCIe read completion and is written to the appropriate location in the descriptor queue.                                                                                                                                    |
| 7    | The DMA fetches the next descriptor and processes its content. As a result, the DMA sends PCIe requests to fetch the packet data from system memory.                                                                                                                   |
| 8    | The packet data is received from PCIe completions and passes through the transmit DMA that performs all programmed data manipulations (various CPU offloading tasks as checksum offload, TSO offload, etc.) on the packet data on the fly.                             |
| 9    | While the packet is passing through the DMA, it is stored into the transmit FIFO. After the entire packet is stored in the transmit FIFO, it is then forwarded to transmit switch module.                                                                              |
| 10   | The transmit switch arbitrates between host and management packets and eventually forwards the packet to the security module.                                                                                                                                          |
| 11   | The security module optionally encrypts the packet and authenticates it using IPsec and passes the packet to the MAC.                                                                                                                                                  |
| 12   | The MAC appends the L2 CRC to the packet and delivers the packet to the integrated PHY.                                                                                                                                                                                |
| 13   | The PHY performs the PCS encoding, scrambling, Low-Density Parity Check (LDPC) encoding, and the other manipulations required to deliver the packet over the copper wires at the selected speed.                                                                       |
| 14   | When all the PCIe completions for a given packet are complete, the DMA updates the appropriate descriptor(s).                                                                                                                                                          |
| 15   | The descriptors are written back to host memory using PCIe posted writes. The head pointer is updated in host memory as well if the X550 is configured to do so.                                                                                                       |
| 16   | An interrupt is generated to notify the software device driver that the specific packet has been read to the X550 and the driver can then release the buffer(s).                                                                                                       |

## 1.8.2 Receive (Rx) Data Flow

Rx data flow provides a high-level description of all data/control transformation steps needed for receiving Ethernet packets.

**Table 1-9. Rx Data Flow**

| Step | Description                                                                                                                                                                                                                                                                                                |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1    | The software device driver creates a descriptor ring and configures one of the X550's receive queues with the address location, length, head, and tail pointers of the ring (one of 128 available Rx queues).                                                                                              |
| 2    | The software device driver initializes descriptor(s) that point to empty data buffer(s). The software device driver places these descriptor(s) in the correct location at the appropriate Rx ring.                                                                                                         |
| 3    | The software device driver updates the appropriate Queue Tail Pointer (RDT).                                                                                                                                                                                                                               |
| 4    | A packet enters the PHY through the copper wires.                                                                                                                                                                                                                                                          |
| 5    | The PHY performs the required manipulations on the incoming signal such as LDPC decoding, de-scrambling, PCS decoding, etc.                                                                                                                                                                                |
| 6    | The PHY delivers the packet to the Rx MAC.                                                                                                                                                                                                                                                                 |
| 7    | The MAC forwards the packet to the security block.                                                                                                                                                                                                                                                         |
| 8    | If the packet is identified as a IPsec packet, it is decrypted.                                                                                                                                                                                                                                            |
| 9    | If the packet matches the pre-programmed criteria of the Rx filtering, it is forwarded to an Rx FIFO.                                                                                                                                                                                                      |
| 10   | The receive DMA fetches the next descriptor from the appropriate host memory ring to be used for the next received packet.                                                                                                                                                                                 |
| 11   | After the entire packet is placed into an Rx FIFO, the receive DMA posts the packet data to the location indicated by the descriptor through the PCIe interface.<br>If the packet size is greater than the buffer size, more descriptor(s) are fetched and their buffers are used for the received packet. |
| 12   | When the packet is placed into host memory, the receive DMA updates all the descriptor(s) that were used by the packet data.                                                                                                                                                                               |
| 13   | The receive DMA writes back the descriptor content along with status bits that indicate the packet information including what offloads were done on that packet.                                                                                                                                           |
| 14   | The X550 initiates an interrupt to the software device driver to indicate that a new received packet is ready in host memory.                                                                                                                                                                              |
| 15   | The software device driver reads the packet data and sends it to the TCP/IP stack for further processing. The software device driver releases the associated buffer(s) and descriptor(s) once they are no longer in use.                                                                                   |

## 2.0 Pin Interface

---

### 2.1 Signal Type Definition

| Signal   | Definition                                                       | DC Specification                                                  |
|----------|------------------------------------------------------------------|-------------------------------------------------------------------|
| In       | Standard 3.3 V I/O buffer, functions as input-only signal.       |                                                                   |
| Out (O)  | Standard 3.3 V I/O buffer, functions as output-only signal.      |                                                                   |
| T/s      | Tri-state is a 3.3 V bi-directional, tri-state input/output pin. |                                                                   |
| O/d      | Open drain enables multiple devices to share as a wire-OR.       | <a href="#">Section 12.4.2</a>                                    |
| A-in     | Analog input signals.                                            | <a href="#">Section 12.4.5</a> and <a href="#">Section 12.4.6</a> |
| A-out    | Analog output signals.                                           | <a href="#">Section 12.4.5</a> and <a href="#">Section 12.4.6</a> |
| A-Inout  | Bi-directional analog signals.                                   |                                                                   |
| B        | Input BIAS.                                                      |                                                                   |
| NCSI-in  | NC-SI 3.3 V input signal.                                        | <a href="#">Section 12.4.3</a>                                    |
| NCSI-out | NC-SI 3.3 V output signal.                                       | <a href="#">Section 12.4.3</a>                                    |
| In-1p2   | 1.2 V input-only signal. 3.3 V tolerance.                        |                                                                   |
| In-Only  | Standard 3.3 V buffer input-only signal.                         |                                                                   |
| Out-Only | Standard 3.3 V buffer output-only signal.                        |                                                                   |
| LVDS-O   | Low voltage differential signal - output.                        |                                                                   |
| Pup      | Pull up.                                                         |                                                                   |
| Pdn      | Pull down.                                                       |                                                                   |

## 2.2 Pin Assignments

### 2.2.1 PCIe

See AC/DC specifications in [Section 12.4.5](#).

## 2.2.3 Serial Flash

See AC/DC specifications in [Section 12.4.4.4](#).

| Pin Name  | Ball #<br>(X550-AT2) | Ball #<br>(X550-BT2) | Type | Internal<br>Pup/Pdn | External<br>Pup/Pdn | Name and Function                                                                                             |
|-----------|----------------------|----------------------|------|---------------------|---------------------|---------------------------------------------------------------------------------------------------------------|
| FLSH_SI   | K3                   | K2                   | Out  | Pup                 |                     | <b>Flash Serial Output:</b> Serial data output to the Flash (used as ENCRYPTION_EN strap in X550-AT2).        |
| FLSH_SO   | J3                   | K1                   | In   |                     |                     | <b>Flash Serial Input:</b> Serial data input from the Flash.                                                  |
| FLSH_SCK  | L1                   | J1                   | Out  |                     |                     | <b>Flash serial clock:</b> Operates at the maximum frequency of 25 MHz.<br>This pin acts as a JTAG_DIS strap. |
| FLSH_CE_N | L2                   | J2                   | Out  |                     | Pup <sup>1</sup>    | <b>Flash Chip Select Output</b>                                                                               |

1. Pup value should be considered as 3.3 K $\Omega$ .

## 2.2.4 SMBus

See the AC/DC specifications in [Section 12.4.4.3](#).

| Pin Name  | Ball #<br>(X550-AT2) | Ball #<br>(X550-BT2) | Type | Internal<br>Pup/Pdn | External<br>Pup/Pdn | Name and Function                                                                                       |
|-----------|----------------------|----------------------|------|---------------------|---------------------|---------------------------------------------------------------------------------------------------------|
| SMBCLK    | F3                   | L2                   | O/d  |                     | Pup <sup>1</sup>    | <b>SMBus Clock:</b> One clock pulse is generated for each data bit transferred.                         |
| SMBD      | F2                   | L1                   | O/d  |                     | Pup <sup>1</sup>    | <b>SMBus Data:</b> Stable during the high period of the clock (unless it is a start or stop condition). |
| SMBALRT_N | F1                   | M2                   | O/d  |                     | Pup <sup>1</sup>    | <b>SMBus Alert:</b> Acts as an interrupt pin of a slave device on the SMBus.                            |

1. Pup value should be considered as 10 K $\Omega$ .

**Note:** If the SMBus is disconnected, use the external pull-up value listed.

## 2.2.5 NC-SI

See AC specifications in [Section 12.4.4.5](#).

| Pin Name               | Ball #<br>(X550-AT2) | Ball #<br>(X550-BT2) | Type     | Internal<br>Pup/Pdn | External<br>Pup/Pdn <sup>1</sup> | Name and Function                                                                                                                                 |
|------------------------|----------------------|----------------------|----------|---------------------|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| NCSI_CLK_IN            | D2                   | G2                   | NCSI-In  |                     | Pdn                              | <b>NC-SI Reference Clock Input:</b> Synchronous clock reference for receive, transmit, and control interface. It is a 50 MHz clock $\pm 100$ ppm. |
| NCSI_TX_EN             | B1                   | G4                   | NCSI-In  |                     | Pdn <sup>2</sup>                 | <b>MC Transmit Enable:</b> Indicates that received data from MC is valid.                                                                         |
| NCSI_TXD0<br>NCSI_TXD1 | D3<br>D4             | H2<br>G3             | NCSI-In  |                     | Pup or Pdn <sup>2</sup>          | <b>MC Transmit Data:</b> Data signals from the MC to the X550.                                                                                    |
| NCSI_CRS_DV            | E3                   | H1                   | NCSI-Out |                     | Pup <sup>3</sup>                 | <b>Carrier Sense/Receive Data Valid (CRS/DV) to MC:</b> Indicates that the data transmitted from the X550 to MC is valid.                         |
| NCSI_RXD0<br>NCSI_RXD1 | E1<br>E2             | H3<br>G1             | NCSI-Out |                     | Pup <sup>3</sup>                 | <b>MC Receive Data:</b> Data signals from the X550 to the MC.                                                                                     |
| NCSI_ARB_IN            | C1                   | F1                   | NCSI-In  |                     | Pdn                              | <b>NC-SI Arbitration In</b>                                                                                                                       |
| NCSI_ARB_OUT           | D1                   | F2                   | NCSI-Out |                     |                                  | <b>NC-SI Arbitration Out</b>                                                                                                                      |

1. Pdn or Pup value should be considered as 10 K $\Omega$ .

2. Should be pulled down if NC-SI interface is disabled.

3. Should be pulled up if NC-SI interface is disabled or if set to multi drop configuration.

## 2.2.6 Software Defined Pins (SDPs)

See AC specifications in [Section 12.4.4.1](#).

See [Section 3.5](#) for more details on configurable SDPs.

| Pin Name                             | Ball #<br>(X550-AT2)     | Ball #<br>(X550-BT2)     | Type | Internal<br>Pup/Pdn      | External<br>Pup/Pdn | Name and Function                                                                                                                                                                                                                                 |

## 2.2.8 RSVD and No-Connect Pins

Connecting RSVD pins based on naming convention:

- NC — Pin is not connected in the package.
- RSVD\_NC — Reserved pin. Should be left unconnected.
- RSVD\_VSS — Reserved pin. Should be connected to GND.
- RSVD\_VCC — Reserved pin. Should be connected to VCC3P3.

| Pin Name                                                                                                                                                                                                             | Ball #<br>(X550-AT2) | Ball #<br>(X550-BT2)                                                                                 | Type                                                                                                         | Name and Function         |

## 2.2.8.1 Pin Differences in the X550-AT Single Port Device

NC = Pin is not connected in the package.

| Name       | Ball # (X550-AT2) | Connection (X550-AT) |
|------------|-------------------|----------------------|
| MDI1_0_p   | B16               | NC                   |
| MDI1_0_n   | C16               | NC                   |
| MDI1_1_p   | A14               | NC                   |
| MDI1_1_n   | B14               | NC                   |
| MDI1_2_p   | A12               | NC                   |
| MDI1_2_n   | B12               | NC                   |
| MDI1_3_p   | A11               | NC                   |
| MDI1_3_n   | B11               | NC                   |
| MDI1_4_p   | A9                | NC                   |
| MDI1_4_n   | B9                | NC                   |
| LAN1_DIS_N | M16               | NC                   |

For additional information on these pins in the X550-AT2, see [Section 2.2.2](#).

## 2.2.9 Miscellaneous

See AC/DC specifications in [Section 12.4.4.1](#).

| Pin Name     | Ball #<br>(X550-AT2) | Ball #<br>(X550-BT2) | Type | Internal<br>Pup/Pdn | External<br>Pup/Pdn | Name and Function                                                                                                                                                                                                               |
|--------------|----------------------|----------------------|------|---------------------|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LAN_PWR_GOOD | N/A                  | L24                  | In   | Pup                 | Pup <sup>1</sup>    | <b>LAN Power Good:</b> A 3.3 V input signal. A transition from low to high initializes the X550 into operation. If not used (BYPASS_POR = 0b), an internal Power-on-Reset (POR) circuit triggers the X550 power up.             |
| BYPASS_POR   | N/A                  | H23                  | In   | Pdn                 | Pdn <sup>2</sup>    | <b>Bypass POR</b>                                                                                                                                                                                                               |
| AUX_PWR      | H3                   | P2                   | In   |                     | Note <sup>3</sup>   | <b>Auxiliary Power Available:</b> When set, indicates that auxiliary power is available and the X550 should support D3 <sub>COLD</sub> power state if enabled to do so. This pin is latched at the rising edge of LAN_PWR_GOOD. |
| MAIN_PWR_OK  | G3                   | R2                   | In   |                     | Note <sup>4</sup>   | <b>Main Power Good:</b> Indicates that platform main power is up. Must be connected externally.                                                                                                                                 |

1. Pup value should be considered as 1 K $\Omega$ .
2. Pdn value should be considered as 1 K $\Omega$ .
3. Connect AUX\_PWR signal to Pup if AUX power is available. Connect Pdn if AUX power is not available. Pup/Pdn value should be considered as 1 K $\Omega$ .
4. Connect MAIN\_PWR\_OK signal to Main Power through Pup resistor. Pup value should be considered as 10 K $\Omega$ .
5. For the X550-AT and X550-AT2, this pin is input during PCIe\_RST\_N assertion only, and is output after that.

## 2.2.10 JTAG

See AC specifications in [Section 12.4.4.2](#).

| Pin Name | Ball #<br>(X550-AT2) | Ball #<br>(X550-BT2) | Type    | Internal<br>Pup/Pdn | External<br>Pup/Pdn | Name and Function                                            |
|----------|----------------------|----------------------|---------|---------------------|---------------------|--------------------------------------------------------------|
| JTCK     | F16                  | Y22                  | In-Only | Pup                 | Pdn <sup>1</sup>    | <b>JTAG Clock Input</b>                                      |
| JTDI     | F14                  | W22                  | In-Only | Pup                 | Pup <sup>2</sup>    | <b>JTAG Data Input</b>                                       |
| JTDO     | F15                  | V22                  | Out     |                     | Pup <sup>3</sup>    | <b>JTAG Data Output</b>                                      |
| JTMS     | G14                  | W21                  | In-Only | Pup                 | Pup <sup>2</sup>    | <b>JTAG TMS Input</b>                                        |
| JTRST_N  | H14                  | W23                  | In-Only | Pup                 | Pdn <sup>1</sup>    | <b>JTAG Reset Input:</b> Active low reset for the JTAG port. |

1. Pdn value should be considered as 470  $\Omega$ .
2. Pup value should be considered as 10 K $\Omega$ .
3. Pup value should be considered as 3.3 K $\Omega$ .

**Note:** If the JTAG is disconnected, use the external pull-up or pull-down values listed.

## 2.2.11 Power Supplies

See AC specifications in [Section 12.3.1](#).

| Pin Name    | Ball # (X550-AT2)                                                                                                                                    | Ball # (X550-BT2)                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Type    | Name and Function   |

## 2.3 Pull-Up/Pull-Down Information

### 2.3.1 External Pull-Ups

Table 2-1 lists external pull-up resistors and their functionality.

**Table 2-1. External Pull-Up Resistors**

| Signal Name   | External Pull-Up/<br>Pull-Down | Notes                                                                                                                                                              |
|---------------|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RESET_N       | Pull-up                        | In X550-BT2 only.                                                                                                                                                  |
| PE_WAKE_N     | Pull-up                        |                                                                                                                                                                    |
| FLSH_SCK      | Pull-down                      | Should be pulled down for normal operation.                                                                                                                        |
| FLSH_SI       | Pull-down/Pull-up              | Serial data output to the Flash. In the X550-BT2, no need for a pull-up or a pull-down. In the X550-AT2, when pulled down, IPsec encryption features are disabled. |
| SMBD          | Pull-up                        |                                                                                                                                                                    |
| SMBCLK        | Pull-up                        |                                                                                                                                                                    |
| SMBALRT_N     | Pull-up                        |                                                                                                                                                                    |
| NCSI_CLK_IN   | Pull-down                      | Should be pulled down if NC-SI interface is disabled.                                                                                                              |
| NCSI_CRS_DV   | Pull-down                      | Only if NC-SI is unused or set to multi drop configuration.                                                                                                        |
| NCSI_RXD[1:0] | Pull-up                        |                                                                                                                                                                    |
| NCSI_TX_EN    | Pull-down                      | Should be pulled down if NC-SI interface is disabled.                                                                                                              |
| NCSI_TXD[1:0] | Pull-down                      |                                                                                                                                                                    |
| JTCK          | Pull-down                      | These resistors should be connected if JTAG is not used. See <a href="#">Section 2.2.10</a> for details.                                                           |
| JTDI          | Pull-up                        |                                                                                                                                                                    |
| JTDO          | Pull-up                        |                                                                                                                                                                    |
| JTMS          | Pull-up                        |                                                                                                                                                                    |
| JTRST_N       | Pull-down                      |                                                                                                                                                                    |
| ENCRYPTION_EN | Pull-down                      | In the X550-BT2 only. When pulled up, IPsec encryption features are enabled.                                                                                       |

## 2.4 Strapping Options

Table 2-2 lists the different strapping pins and their sampling point in both packages.

**Table 2-2. Strapping Options**

| Strap         | X550-BT2 Location  | X550-AT2 Location | Latched At                             |
|---------------|--------------------|-------------------|----------------------------------------|
| LAN0_DIS_N    | LAN0_DIS_N (K23)   | LAN0_DIS_N (M15)  | LAN_PWR_GOOD, PE_RST_N, In-band Reset. |
| LAN1_DIS_N    | LAN1_DIS_N (K24)   | LAN1_DIS_N (M16)  | LAN_PWR_GOOD, PE_RST_N, In-band Reset. |
| ENCRYPTION_EN | ENCRYPTION_EN (M1) | FLSH_SI (K3)      | LAN_PWR_GOOD                           |

## 2.5 Ball Out — Top View Through Package

|   | 1            | 2           | 3                     | 4         | 5        | 6        | 7        | 8        | 9        | 10       | 11       | 12       | 13       | 14          | 15         | 16         |   |

## 3.0 Interconnects

---

### 3.1 PCI Express (PCIe)

#### 3.1.1 General Overview

The X550 supports Rev 3.0 of the PCIe base specification.

On top of the capabilities required by the PCIe specifications, The X550 supports optional functionality as listed in this section:

- All PCI functions are native PCIe functions.
- Physical Layer:
  - Support for 2.5 GT/s, 5 GT/s, and 8 GT/s
  - Interface width of 1, 4 or 8 PCIe lanes (8 lanes are supported only in the X550-BT2, and only at 5 GT/s or 2.5 GT/s speeds.)
  - Full swing and half swing signaling
  - Lane reversal
- Transaction layer mechanisms:
  - 64-bit and 32-bit memory address spaces
  - Removal of I/O BAR (optional)
  - Relaxed ordering
  - Flow control update timeout mechanism
  - ID-based ordering (IDO)
  - Packet sizes: Maximum packet size: 512, Maximum read request size: 2 KB
  - Function-Level Reset (FLR)
  - TLP Processing Hints (TPH)
- Reliability:
  - Advanced Error Reporting (AER)
  - End-to-End CRC (ECRC) generation and checking
  - Recovery from data poisoning
  - Completion Timeout

- Power management:
  - Active state power management (L1 state)
  - Wake capability
  - Latency Tolerance Reporting (LTR)
- DFT and DFM support for high-volume manufacturing.
- The X550 supports the following Extended Capabilities:
  - Advanced Error Reporting (AER)
  - Device Serial Number
  - Alternative RID Interpretation (ARI)
  - Single Root I/O Virtualization (SR-IOV)
  - TPH Requester — Access Control Services (ACS)

## 3.1.2 Transaction Layer

### 3.1.2.1 Transaction Types Accepted by the X550

Table 3-1 summarizes the transactions accepted by the device and their attributes.

**Table 3-1. Transaction Types Accepted by the Transaction Layer**

| Transaction Type            | FC Type     | Tx Layer Reaction | Hardware Should Keep Data from Original Packet |
|-----------------------------|-------------|-------------------|------------------------------------------------|
| Configuration Read Request  | NPH         | CPLH + CPLD       | Requester ID, TAG, attribute                   |
| Configuration Write Request | NPH + NPD   | CPLH              | Requester ID, TAG, attribute                   |
| Memory Read Request         | NPH         | CPLH + CPLD       | Requester ID, TAG, attribute                   |
| Memory Write Request        | PH + PD     | -                 | -                                              |
| IO Read Request             | NPH         | CPLH + CPLD       | Requester ID, TAG, attribute                   |
| IO Write Request            | NPH + NPD   | CPLH              | Requester ID, TAG, attribute                   |
| Read Completions            | CPLH + CPLD | -                 | -                                              |
| Message                     | PH          | -                 | -                                              |

#### Flow Control Types Legend:

- CPLD — Completion Data Payload
- CPLH — Completion Headers
- NPD — Non-Posted Request Data Payload
- NPH — Non-Posted Request Headers
- PD — Posted Request Data Payload
- PH — Posted Request Headers

### 3.1.2.1.1 Size of Target Accesses

#### 3.1.2.1.1.1 Memory Accesses

##### Rules for accesses to the CSR space (both memory BAR and MSI-X BAR):

- Write accesses:
  - Zero-length writes have no internal impact (nothing written, no effect such as clear-by-write). The transaction is treated as a successful operation (no error event).
  - CSR writes are 32-bit or 64-bit only. Larger or partial CSR writes are handled as Completer Abort - data is dropped and an error is generated per PCIe rules.
- Read accesses:
  - Partial reads with at least one byte disabled are handled as a full read. Any side effect of the full read (such as clear by read) is also applicable to partial reads. The completion on PCIe obeys the specification rules regarding the number of bytes reported in the completion.
  - Zero-length reads generate a completion, but the register is not accessed and undefined data is returned.
  - CSR reads are 32-bit or 64-bit only. Larger CSR read requests are handled as Completer Abort. The completion includes a CA status and an error is generated per PCIe rules.
  - Some 64-bit reads are handled atomically (i.e. not interleaved with any other requests). This applies mainly to reading counters, where all 64-bit need to be read simultaneously. Such registers are explicitly marked in their description.

##### Rules for accessing the Flash space in the memory BAR or the Expansion ROM BAR:

- Write accesses:
  - Writes to Flash are 8-bit wide only.
  - Any larger write accesses are handled as Completer Abort - data is dropped and an error is generated per PCIe rules.
- Read accesses:
  - Reads to Flash are 32-bit wide.
  - Partial reads with at least one byte disabled are handled internally as a full read. That is, any side effect of the full read (such as clear by read) is also applicable to partial reads. The completion on PCIe obeys the specification rules regarding the number of bytes reported in the completion.
  - Larger CSR read requests are handled as Completer Abort - the completion includes a CA status and an error is generated per PCIe rules.

### 3.1.2.1.1.2 I/O Accesses

#### Rules for accesses to the I/O BAR:

- Write accesses:
  - Write accesses are 32-bit wide.
  - Zero-length writes have no internal impact (nothing written, no effect such as clear-by-write). The transaction is treated as a successful operation (no error event).
  - Other accesses (partial writes, larger writes) are handled as Completer Abort - data is dropped and an error is generated per PCIe rules.
- Read accesses:
  - Reads to the I/O BAR are 32-bit wide.
  - Partial reads with at least one byte disabled are handled internally as a full read. That is, any side effect of the full read (such as clear by read) is also applicable to partial reads. The completion on PCIe obeys the specification rules regarding the number of bytes reported in the completion.
  - Larger CSR read requests are handled as Completer Abort - the completion includes a CA status and an error is generated per PCIe rules.

### 3.1.2.1.1.3 Messages

MCTP messages may contain payload of up to 64 bytes.

### 3.1.2.1.2 Support for Dynamic Changes

The X550 captures the Bus Number and Device Number per each Configuration Write Request. However, dynamic change of Bus Number or Device Number is not supported. Rather, the PCIe link should be quiescent prior to such a change, including reception of all completion for previous requests.

## 3.1.2.2 Transaction Types Initiated by the X550

**Table 3-2. Transaction Types Initiated by the Transaction Layer**

| Transaction Type                       | Payload Size          | FC Type     |
|----------------------------------------|-----------------------|-------------|
| Configuration Read Request Completion  | Dword                 | CPLH + CPLD |
| Configuration Write Request Completion | -                     | CPLH        |
| IO Read Request Completion             | Dword                 | CPLH + CPLD |
| IO Write Request Completion            | -                     | CPLH        |
| Read Request Completion                | Dword/Qword           | CPLH + CPLD |
| Memory Read Request                    | -                     | NPH         |
| Memory Write Request                   | <= MAX_PAYLOAD_SIZE   | PH + PD     |
| Message                                | 64 bytes <sup>1</sup> | PH          |

1. MCTP messages contain payload.

### Configuration values:

- Max Payload Size — The value of the *Max Payload Size Supported* field in the Device Capabilities Register is loaded from NVM.
  - Hardware default is 512.
  - System software then programs the actual value into the *Max Payload Size* field of the Device Control Register.
    - Non-ARI mode: If not all functions are programmed with the same value, the max payload size used for all functions is the minimum value programmed among all functions.
    - ARI mode: *Max\_Payload\_Size* is determined solely by the setting in Function 0.
- Max Read Request Size — The X550 supports read requests of up to 2 KB.
  - The actual maximum size of a read request is defined as the minimum {2 KB, *Max Read Request Size* field in the Device Control Register}.

The number of outstanding memory read requests is bounded by the following:

- The total number of outstanding requests is not more than 32 requests. These are shared by all sources for memory reads.

#### 3.1.2.2.1 Data Alignment

Requests must never specify an address/length combination that causes a memory space access to cross a 4 KB boundary. The X550 therefore breaks requests into 4 KB-aligned requests (if needed). This does not place any requirement on software. However, if software allocates a buffer across a 4 KB boundary, hardware issues multiple requests for the buffer. Software should consider aligning buffers to a 4 KB boundary in cases where it improves performance. The maximum size of a read request is defined as the minimum {2 KB bytes, *Max\_Read\_Request\_Size*}

The general rules for packet alignment are as follows. Note that these apply to all the X550 requests (read/write):

- The length of a single request does not exceed the PCIe limit of *MAX\_PAYLOAD\_SIZE* for write and *MAX\_READ\_REQ* for read.
- The length of a single request does not exceed the X550 internal limitations.
- A single request does not span across different memory pages as noted by the 4 KB boundary alignment previously mentioned.

If a request can be sent as a single PCIe packet and still meet the general rules for packet alignment, it is not broken at the cache line boundary but rather sent as a single packet. However, if any of the three general rules require that the request is broken into two or more packets, the request is broken at the cache line boundary.

For requests with data payload, if the payload size is larger than (*MAX\_PAYLOAD\_SIZE* - *CACHELINE\_SIZE*), the request is broken into multiple TLPs starting at the first cache line boundary following the (*MAX\_PAYLOAD\_SIZE* - *CACHELINE\_SIZE*) bytes. For example, if *MAX\_PAYLOAD\_SIZE* = 256 bytes and *CACHELINE\_SIZE* = 64 bytes, a 1 KB request starting at address 0x...10 is broken into TLPs such that the first TLP contains 240 bytes of payload (since 240B + 10h = 256B is on cache line boundary).

The system cache line size is controlled by the *PCI\_CNF2.CACHELINE\_SIZE* bit, loaded from the NVM. Note that the Cache Line Size Register in the PCI configuration space is not related to the *PCI\_CNF2.CACHELINE\_SIZE* and is solely for software use.

### 3.1.2.3 Messages

#### 3.1.2.3.1 Received Messages

Message packets are special packets that carry a message code. The upstream device transmits special messages to the X550 by using this mechanism. The transaction layer decodes the message code and responds to the message accordingly.

**Table 3-3. Supported Messages in the X550 — as a Receiver**

| Message Code [7:0]                       | Routing r2r1r0         | Message                                         | X550 Later Response                                                                                         |
|------------------------------------------|------------------------|-------------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| 0x14                                     | 100b                   | PM_Active_State_NAK                             | Accepted                                                                                                    |
| 0x19                                     | 011b                   | PME_Turn_Off                                    | Accepted                                                                                                    |
| 0x40, 0x41, 0x43, 0x44, 0x45, 0x47, 0x48 | 100b                   | Ignored messages (used to be hot-plug messages) | Silently drop                                                                                               |
| 0x50                                     | 100b                   | Slot power limit support (has one Dword data)   | Silently drop.                                                                                              |
| 0x7E                                     | 000b, 010b, 011b, 100b | Vendor defined type 0                           | Drop and handle as an Unsupported request.                                                                  |
| 0x7F                                     | 100b                   | Vendor defined type 1                           | Silently drop.                                                                                              |
| 0x7F                                     | 010b, 011b, 000b       | Vendor defined type 1                           | Send to MCTP reassembly if Vendor ID = 0x1AB4 (DMTF) and VDM code = 0000b (MCTP). Otherwise, silently drop. |
| 0x00                                     | 011b                   | Unlock                                          | Silently drop.                                                                                              |

#### 3.1.2.3.2 Transmitted Messages

The transaction layer is also responsible for transmitting specific messages to report internal/external events (such as interrupts and PMEs).

**Table 3-4. Supported Messages in the X550 — as a Transmitter**

| Message Code [7:0] | Routing r2r1r0 | Message          |
|--------------------|----------------|------------------|
| 0x20               | 100b           | Assert INT A     |
| 0x21               | 100b           | Assert INT B     |
| 0x22               | 100b           | Assert INT C     |
| 0x23               | 100b           | Assert INT D     |
| 0x24               | 100b           | De- Assert INT A |
| 0x25               | 100b           | De- Assert INT B |
| 0x26               | 100b           | De- Assert INT C |
| 0x27               | 100b           | De- Assert INT D |
| 0x30               | 000b           | ERR_COR          |
| 0x31               | 000b           | ERR_NONFATAL     |
| 0x33               | 000b           | ERR_FATAL        |
| 0x18               | 000b           | PM_PME           |

**Table 3-4. Supported Messages in the X550 — as a Transmitter (Continued)**

| Message Code [7:0] | Routing r2r1r0   | Message    |
|--------------------|------------------|------------|
| 0x1B               | 101b             | PME_TO_Ack |
| 0x10               | 100b             | LTR        |
| 0x7F               | 000b, 010b, 011b | VDM        |

### 3.1.2.3.3 Vendor Defined Messages (VDM)

The following vendor defined messages are supported:

- DMTF MCTP

#### 3.1.2.3.3.1 MCTP VDMs

MCTP VDMs are supported as both master and target. The following header fields are involved (see Figure 3-1):

- Fmt — Set to 11b to indicate 4 Dword header with data.
- Type
  - [4:3] Set to 10b to indicate a message.
  - [2:0] Routing r2r1r0 = 000b, 010b or 011b.
- Traffic Class — Set to 000b.
- TLP Digest — Set to 0b (no ECRC) or 1 (ECRC) according to the PCI\_CAPSUP.ECRC\_MCTP\_GEN bit.
- Error Present - Set to 0.
- Attributes[1:0] — Set to 01 (no snoop).
- Tag field — Indicates this is an MCTP packet and the size of padding to Dword alignment added.
- Message code = 0x7F (Type 1 VDM).
- Destination ID — captures the target B/D/F for Route by ID. Otherwise, reserved.
- Vendor ID = 0x1AB4 (DMTF).

**Figure 3-1. MCTP Over PCIe Header Format**

|                                                                   |                               |   |           |   |                               |   |             |                           |             |                          |                                             |                        |
|-------------------------------------------------------------------|-------------------------------|---|-----------|---|-------------------------------|---|-------------|---------------------------|-------------|--------------------------|---------------------------------------------|------------------------|
| FMT<br>011                                                        | Type<br>10r2r1r0 <sup>1</sup> | R | TC<br>000 | R | A<br>t<br>t<br>r <sup>2</sup> | R | T<br>H<br>2 | T<br>D<br>2               | E<br>P<br>2 | Attr<br>[1:0]<br>2       | AT<br>00                                    | Length<br>00_000x_xxxx |
| PCI Requester ID                                                  |                               |   |           |   |                               |   |             | PCI Tag Field             |             |                          | Message Code<br>Vendor Defined = 0111_1111b |                        |
|                                                                   |                               |   |           |   |                               |   |             | R                         | Pad<br>Len  | MCTP VDM<br>code - 0000b |                                             |                        |
| PCI Target ID (For Route by ID messages,<br>otherwise = Reserved) |                               |   |           |   |                               |   |             | Vendor ID = 0x1AB4 (DMTF) |             |                          |                                             |                        |

1. r2r1r0 =  
000b: Route to Root Complex  
010b: Route by ID  
011b: Broadcast from Root Complex
2. TD = 0, EP = 0, IC = 0, TH = 0, Attr[2:0] = 0 for sent packets and is ignored for received packets.

### 3.1.2.4 Transaction Attributes

#### 3.1.2.4.1 Traffic Class (TC) and Virtual Channels (VC)

The X550 only supports TC = 0 and VC = 0 (default).

#### 3.1.2.4.2 TLP Processing Hints (TPH)

The X550 supports the TPH capability defined in the PCI Express specification. It does not support Extended TPH requests.

Existence of a TLP Processing Hint (TPH) is indicated on the PCIe link by setting the TH bit in the TLP header. Using the PCIe TLP Steering Tag (ST) and Processing Hints (PH) fields, The X550 can provide hints to the root complex about the destination (socket ID) and about data access patterns (locality in Cache) when executing DMA memory writes or read operations.

The X550 exposes a PCIe TPH capability structure (See [Section 9.2.4.5](#)) with no steering table.

See [Section 7.5](#) for details on the usage of TPH.

### 3.1.2.5 Ordering Rules

The X550 meets the PCIe ordering rules by following the PCI simple device model:

1. Deadlock Avoidance — The X550 meets the PCIe ordering rules that prevent deadlocks:
  - a. Posted writes overtake stalled read requests. This applies to both target and master directions. For example, if master read requests are stalled due to lack of credits, master posted writes are allowed to proceed. On the target side, it is acceptable to timeout on stalled read requests to allow later posted writes to proceed.
  - b. Target posted writes overtake stalled target configuration writes.
  - c. Completions overtake stalled read requests. This applies to both target and master directions. For example, if master read requests are stalled due to lack of credits, completions generated by the X550 are allowed to proceed.
2. Descriptor/Data Ordering — The X550 ensures that a Rx descriptor is written back on PCIe only after the data that the descriptor relates to is written to the PCIe link. MSI and MSI-X Ordering Rules. System software might change the MSI or MSI-X tables during run-time. Software expects that interrupt messages issued after the table has been updated are using the updated contents of the tables.
  - a. Since software does not know when the tables are actually updated in the X550, a common scheme is to issue a read request to the MSI or MSI-X table (a PCI configuration read for MSI and a memory read for MSI-X). Software expects that any message issued following the completion of the read request, is using the updated contents of the tables.
  - b. Once an MSI or MSI-X message is issued using the updated contents of the interrupt tables, any consecutive MSI or MSI-X message does not use the contents of the tables prior to the change.
3. The X550 meets the rules relating to independence between target and master accesses:
  - a. The acceptance of a target posted request does not depend upon the transmission of any TLP.
  - b. The acceptance of a target non-posted request does not depend upon the transmission of a non-posted request.
  - c. Accepting a completion does not depend upon the transmission of any TLP.

### 3.1.2.5.1 Relaxed Ordering

The X550 takes advantage of the relaxed ordering rules in PCIe. By setting the relaxed ordering bit in the packet header, the X550 enables the system to optimize performance in the following cases:

1. Relaxed ordering for descriptor and data reads — When the X550 masters a read transaction, its split completion has no ordering relationship with the writes from the CPUs (same direction). It should be allowed to bypass the writes from the CPUs.
2. Relaxed ordering for receiving data writes — When the X550 masters receive data writes, it also enables them to bypass each other in the path to system memory because software does not process this data until their associated descriptor writes are done.
3. The X550 cannot relax ordering for receive descriptor writes or an MSI write.

Relaxed ordering is enabled in the X550 by clearing the CTRL\_EXT.RO\_DIS bit. Relaxed ordering is further controlled through the *Enable Relaxed Ordering* bit in the PCIe Device Control Register (Section 9.2.3.6.5).

### 3.1.2.5.2 ID-Based Ordering (IDO)

ID-based ordering was introduced in the PCIe rev. 2.1 specification. When enabled, the X550 sets IDO in all applicable TLPs defined in the PCIe specification.

This capability allows a supporting root complex to relax ordering rules for TLPs sent by different requesters.

IDO is enabled when all of the following conditions are met:

- The NVM PCI\_CAPSUP.IDO Enable bit is set (Section 6.4.5 and Section 8.2.2.5.11).
- The PCIe IDO Request Enable bit (for requests) or the IDO Completion Enable bit (for completions) in Device Control 2 Register is set (Section 9.2.3.6.11).

## 3.1.2.6 Flow Control

### 3.1.2.6.1 Flow Control Rules

The X550 only implements the default Virtual Channel (VC0). A single set of credits is maintained for VC0.

**Table 3-5. Flow Control Credits Allocation**

| Credit Type                     | Operations                                                                                | Number of Credits (Dual Port)                                               |
|---------------------------------|-------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------|
| Posted Request Header (PH)      | Target write Message (one unit)                                                           | 16 credit units to support tail write at wire speed.                        |
| Posted Request Data (PD)        | Target Write (Length/16 bytes = one) Message (one unit)                                   | max{MAX_PAYLOAD_SIZE/16, 32}.                                               |
| Non-Posted Request Header (NPH) | Target read (one unit)<br>Configuration read (one unit)<br>Configuration write (one unit) | Four credit units (to enable concurrent target accesses to both LAN ports). |
| Non-Posted Request Data (NPD)   | Configuration write (one unit)                                                            | Four credit units.                                                          |
| Completion Header (CPLH)        | Read completion (N/A)                                                                     | Infinite (accepted immediately).                                            |
| Completion Data (CPLD)          | Read completion (N/A)                                                                     | Infinite (accepted immediately).                                            |

#### Rules for FC updates:

- UpdateFC packets are sent immediately when a resource becomes available.
- The X550 follows the PCIe recommendations for frequency of UpdateFC FCPs.
- Specific rules apply in L0 or L0s link states. See PCIe specification.

### 3.1.2.6.2 Flow Control Timeout Mechanism

The X550 implements the optional flow control update timeout mechanism. See the PCIe specification.

### 3.1.2.7 End-to-End CRC (ECRC)

The X550 supports ECRC as defined in the PCIe specification. The following functionality is provided:

- Inserting ECRC in all transmitted TLPs:
  - The X550 indicates support for inserting ECRC in the *ECRC Generation Capable* bit of the PCIe configuration registers. This bit is loaded from the *ECRC Generation* NVM bit.
  - Inserting ECRC is enabled by the *ECRC Generation Enable* bit of the PCIe configuration registers. VFs follow the behavior of their PF.
    - ECRC is not added to MCTP messages (per MCTP specification) unless the `PCI_CAPSUP.ECRC_MCTP_GEN` bit is set.
- ECRC is checked on all incoming TLPs. A packet received with an ECRC error is dropped. Note that for completions, a completion timeout occurs later (if enabled).
  - The X550 indicates support for ECRC checking in the *ECRC Check Capable* bit of the PCIe configuration registers. This bit is loaded from the *ECRC Check* NVM bit.
  - Checking of ECRC is enabled by the *ECRC Check Enable* bit of the PCIe configuration registers. ECRC checking is done if enabled by at least one physical function (enablement is not done via VFs).
- ECRC errors are reported on all physical functions (PFs) enabled for ECRC checking.
- System software can configure ECRC independently per each physical function.

## 3.1.3 Link Layer

### 3.1.3.1 ACK/NAK Scheme

The X550 supports two alternative schemes for ACK/NAK rate:

- NAKs are sent as soon as identified.
- ACKs are sent per Section 3.5.3.1 (Table 3-7, Table 3-8, and Table 3-9) in the PCIe Base Specification.

### 3.1.3.2 Supported DLLPs

The following DLLPs are supported by the X550 as a receiver:

- ACK
- NAK
- PM\_Request\_Ack
- InitFC1-P
- InitFC1-NP
- InitFC1-Cpl
- InitFC2-P
- InitFC2-NP
- InitFC2-Cpl
- UpdateFC-P
- UpdateFC-NP
- UpdateFC-Cpl

The following DLLPs are supported by the X550 as a transmitter:

- ACK
- NAK
- PM\_Enter\_L1
- PM\_Enter\_L23
- InitFC1-P
- InitFC1-NP
- InitFC1-Cpl
- InitFC2-P
- InitFC2-NP
- InitFC2-Cpl
- UpdateFC-P
- UpdateFC-NP

**Note:** UpdateFC-Cpl is not sent because of the infinite FC-Cpl allocation.

### 3.1.3.3 Transmit End Data Bit (EDB) Nullifying — End Bad

A TLP may be signaled as EDB or poisoned if during its transmission from the device, an internal memory error is detected that may corrupt the TLP payload.

## 3.1.4 Physical Layer

### 3.1.4.1 Link Speed

The X550 supports PCIe 2.1 and PCIe 3.0.

The following configuration controls link speed:

- **PCIe Supported Link Speeds bit** — Indicates the link speeds supported by the X550.
- **PCIe Current Link Speed bit** — Indicates the negotiated link speed.
- **PCIe Target Link Speed bit** — used to set the target compliance mode speed when software is using the *Enter Compliance* bit to force a link into compliance mode. The default value is loaded from the highest link speed supported defined by the above *Supported Link Speeds*.

The X550 does not initiate a hardware autonomous speed change.

The X550 supports entering compliance mode at the speed indicated in the *Target Link Speed* field in the PCIe Link Control 2 register ([Section 9.2.3.6.13](#)). Compliance mode functionality is controlled via the PCIe Link Control 2 register.

### 3.1.4.2 Link Width

The X550 supports a maximum link width of x8, x4, or x1. The maximum link width is loaded into the *Max Link Width* field of the PCIe Capability register (*LCAP[11:6]*). Hardware default is the x4 link for the X550-AT2, and x8 link for the X550-BT2.

During link configuration, the platform and the X550 negotiate on a common link width. The link width must be one of the supported PCIe link widths (x1, x4, x8), such that:

- If Maximum Link Width = x8, the X550 negotiates to either x8, x4 or x1.
- If Maximum Link Width = x4, the X550 negotiates to either x4 or x1
- If Maximum Link Width = x1, the X550 only negotiates to x1

When negotiating for x4, or x1 link, the X550 may negotiate the link to reside starting from physical lane 0 or starting from physical lane 4.

The X550 does not initiate a hardware autonomous link width change.

When operating in x8 link width the X550 does not support Gen3 link speed (8GT/s).

The x8 link width is available only in the X550-BT2.

### 3.1.4.3 Lane Configurations

The X550 supports lane reversal and degraded modes.

The following general rules determine how the device reacts in different cases of lanes configuration:

- If lane 0 is found valid, the X550 does not initiate lane reversal. The link partner (LP) may initiate lane reversal (to end up with an optimal lane width) and the X550 consents with the lane reversal.
- If lane 0 is found invalid, the X550 initiates lane reversal. Lane reversal succeeds if the link partner supports link reversal.
- If the lanes at both ends of the port (i.e. lanes 0 & 7 for x8, lanes 0 & 3 for x4, lane 0 for x1) are invalid, a link is not established.

**Note:** Some of the configurations or transitions assume lane reversal is done by the link partner. If the link partner does not support a specific transition, the respective configuration is not provided on that system.

Figure 3-2, Figure 3-3, and Figure 3-4 depict the initial link width configuration and link degradation options. In Figure 3-2 and Figure 3-3, the upper part of the Figure describes link options where the Link Partner (LP) and the X550 (NIC) are aligned. The bottom part of the Figure describes link options where the Link Partner and the X550 are reversed in order.

- Figure 3-2 applies when either the Link partner or the X550 is physically set to x8.
- Figure 3-3 applies when either the Link partner or the X550 is physically set to x4 and both are not physically set x8.
- Figure 3-4 applies when both the Link partner or the X550 is physically set to x1.

Figure 3-2. Link Width Configurations for a x8 Port

**Figure 3-3. Link Width Configurations for a x4 Port**

**Figure 3-4. Link Width Configurations for a x1 Port**

### 3.1.4.4 Receiver Framing Requirements

This section applies to Gen3 operation only and lists the optional capabilities defined in Section 4.2.2.3.3 (Receiver Framing Requirements) of the PCIe base specification.

The device implements the optional Gen3 receiver framing error checks other than:

- TLP Token length=0
- Mixed order sets across lanes

## 3.1.5 Error Events and Error Reporting

### 3.1.5.1 General Description

PCIe defines three error reporting paradigms: the baseline capability, the Advanced Error Reporting (AER) capability, and a proprietary mechanism. The baseline error reporting capabilities are required of all PCIe devices and define the minimum error reporting requirements. The AER capability is defined for more robust error reporting and is implemented with a specific PCIe capability structure. Both mechanisms are supported by the X550. The proprietary error reporting mechanism used for error better handled by the software device driver using internal CSRs is described in [Section 3.1.5.8](#).

The *SERR# Enable* and the *Parity Error* bits from the Legacy Command register also take part in the error reporting and logging mechanism.

In a multi-function device, PCIe errors that are not related to any specific function within the device are logged in the corresponding status and logging registers of all functions in that device. [Figure 3-5](#) shows, in detail, the flow of error reporting in the X550.

### Figure 3-5. Error Reporting Mechanism

### 3.1.5.2 Error Events

Table 3-6 lists the error events identified by the X550 and the response in terms of logging, reporting, and actions taken. Refer to the PCIe specification for the effect on the PCI Status register.

**Table 3-6. Response and Reporting of PCIe Error Events**

| Error Name                     | Error Events                                                                                                                                                                                                                                                                                                                                                                     | Default Severity                            | Action                                                                                                                                                                                                                                                                                                                                                                                          |

### 3.1.5.3 Completion Timeout Mechanism

The X550 supports completion timeout as defined in the PCIe specification.

The X550 controls the following aspects of completion timeout:

- Disabling or enabling completion timeout.
  - The PCIe *Completion Timeout Disable Supported* bit in the Device Capabilities 2 Register ([Section 9.2.3.6.10](#)) is hardwired to 1b to indicate that disabling completion timeout is supported
  - The PCIe *Completion Timeout Disable* bit in Device Control 2 Register controls whether completion timeout is enabled
- A programmable range of timeout values.
  - The X550 supports all four ranges as programmed in the *Completion Timeout Ranges Supported* field of the Device Capabilities 2 Register. The actual completion timeout value is written in the *Completion Timeout Value* field of Device Control 2 Register ([Section 9.2.3.6.10](#))

The following sequence takes place when completion timeout is detected:

- The appropriate message is sent on PCIe as described in [Table 3-6](#).
- The affected queue or client takes action based on the nature of the original request.
- An interrupt is issued to the respective PF.

#### 3.1.5.4 Error Forwarding (TLP Poisoning)

If a TLP is received with an error-forwarding trailer, the packet is dropped and is not delivered to its destination. The X550 then reacts as listed in [Table 3-6](#).

The following sequence takes place when a poisoned TLP is received:

- The appropriate message is sent on PCIe as described in [Table 3-6](#).
- An interrupt is issued.
- If the TLP is a completion, a completion timeout follows at some later time. Processing continues as described in [Section 3.1.5.3](#).

System logic is expected to trigger a system-level interrupt to signal the operating system of the problem. Operating systems can then stop the process associated with the transaction, re-allocate memory to a different area instead of the faulty area, etc.

#### 3.1.5.5 Completion with Unsuccessful Completion Status

A completion arriving with unsuccessful completion status (either UR or CA) is dropped and not delivered to its destination. A completion timeout follows at some later time. Processing continues as described in [Section 3.1.5.3](#).

#### 3.1.5.6 Error Pollution

Error pollution can occur if error conditions for a given transaction are not isolated to the error's first occurrence. If the PHY detects and reports a receiver error, to avoid having this error propagate and cause subsequent errors at the upper layers, the same packet is not signaled at the data link or transaction layers. Similarly, when the data link layer detects an error, subsequent errors that occur for the same packet are not signaled at the transaction layer.

#### 3.1.5.7 Blocking on Upper Address

The PCI\_UPADD register blocks master accesses from being sent out on PCIe if the TLP address exceeds some upper limit. Bits [31:1] correspond to bits [63:33] in the PCIe address space, respectively.

When a bit is set in GLPCI\_UPADD[31:1], any transaction in which the corresponding bit in its address is set, is blocked and not sent over PCIe. If all register bits are cleared, there is no effect (in other words, no TLPs are blocked by this mechanism).

The PCI\_UPADD register is loaded from NVM with a value allowing all addresses to pass. The software device driver should override this value with a system dependent value.

Processing a blocked transaction:

- Write transaction
  - The transaction is dropped.
  - Set the “Exceeded upper address limit (write requests)” event in the PCIe errors register (see [Section 3.1.5.8](#)).
  - An interrupt is issued as described in [Section 3.1.5.8](#).

- Read transaction
  - The transaction is dropped.
  - Set the “Exceeded upper address limit (read requests)” event in the PCIe errors register (see [Section 3.1.5.8](#)).
  - The originating internal client is notified.
  - The affected queue or client takes action based on the nature of the original request. An interrupt is issued to the respective PF.

### 3.1.5.8 Proprietary Error Reporting

The PCIe specification defines how to report errors to system software. There are, however, error events that the device driver should be aware of or that the device driver is in better position to handle and recover from. This section describes the mechanism to report PCIe related errors to device drivers.

Several CSRs are dedicated to this functionality, with a separate bit allocated per error type (see [Table 3-7](#)):

- The “PCIe Errors Reported” register (PCI\_PCIERR - RO) indicates which errors are reported using this mechanism. It is shared by all PFs. It is loaded from NVM. All non-reserved errors are enabled.
- The “PCIe Interrupt Cause” register (PCI\_ICAUSE - RW1C) indicates pending errors for errors set in the PCIe Errors Reported register. It is dedicated per PF.
- The “PCIe Interrupt Enable” register (PCI\_IENA - RW) determines if an interrupt should be issued to the respective PCI function on an error event. It is dedicated per PF.

Reporting an error to the PF driver involves the following steps:

- The device checks if the respective bit is set in the PCIe Errors Reported register. If cleared, done. Else, continue
- The respective bit is set in the “PCIe Interrupt Cause” register
- If the respective bit is set in the “PCIe Interrupt Enable” register, an interrupt is issued to the PCI function. The *PCI\_EXCEPTION* cause is used (see the EICR register - [Section 8.2.2.6.1](#)).

**Table 3-7. PCIe Errors Reported to Device Software**

| Error Event                                   | Index | Description and Comments                                                                             | Function Association                                                                          |
|-----------------------------------------------|-------|------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------|
| Exceeded upper address limit (read requests)  | 00    | See <a href="#">Section 3.1.5.7</a>                                                                  | Sent to PF                                                                                    |
| Exceeded upper address limit (write requests) | 01    | See <a href="#">Section 3.1.5.7</a>                                                                  | Sent to PF                                                                                    |
| Reserved                                      | 02    | Reserved entries                                                                                     | N/A                                                                                           |
| Poisoned TLP received                         | 03    | See <a href="#">Section 3.1.5.4</a>                                                                  | Sent to PF                                                                                    |
| Reserved                                      | 04-05 | Reserved entries                                                                                     | N/A                                                                                           |
| ECRC error detected                           | 06    | ECRC check failed on a received TLP. See <a href="#">Section 3.1.5.7</a>                             | Sent to all PFs                                                                               |
| Unsupported Request - Request Type            | 07    | Request causes an Unsupported Request due to receipt of TLP with unsupported Request Type            | Sent to PF                                                                                    |
| Unsupported Request - Vendor Message          | 08    | Request causes an Unsupported Request due to receipt of an Unsupported Vendor Defined Type 0 Message | Sent to PF unless r[2:0] = <i>Broadcast from Root Complex</i> , in which case sent to all PFs |

**Table 3-7. PCIe Errors Reported to Device Software (Continued)**

| Error Event                           | Index   | Description and Comments                                                                                                          | Function Association |
|---------------------------------------|---------|-----------------------------------------------------------------------------------------------------------------------------------|----------------------|
| Unsupported Request - Message Code    | 09      | Request causes an Unsupported Request due to receipt of an invalid Message Code                                                   | Sent to PF           |
| Unsupported Request - Function Number | 10      | Request causes an Unsupported Request due to receipt of a not-supported Function Number                                           | Sent to all PFs      |
| Unsupported Request - Address Range   | 11      | Request causes an Unsupported Request due to receipt of a not-supported Address Range                                             | Sent to PF           |
| Unsupported Request - D3hot           | 12      | Request causes an Unsupported Request due to receipt of a Request TLP during D3hot, other than Configuration and Message requests | Sent to PF           |
| Completer abort - target size         | 13      | Received Target Access with illegal data size per <a href="#">Section 3.1.2.1.1</a> (CA)                                          | Sent to PF           |
| Reserved                              | 14 - 31 | Reserved entries                                                                                                                  | N/A                  |

### 3.1.6 Performance and Statistics Counters

The X550 incorporates counters to track the behavior and performance of the PCIe interconnect. The X550 implements several types of counters:

- Transaction layer event counters — [Section 3.1.6.1](#)
- Link and Physical layer event counters — [Section 3.1.6.2](#)
- Bandwidth counters — [Section 3.1.6.3](#)
- Latency counters — [Section 3.1.6.4](#)

General characteristics of the counters:

- Software can reset, stop, or start the counters.
- The counters are shared by all PCI functions (“Service” mode of sharing).

Part of the registers that manage the operation of the performance counters are accessed via the PCI\_LCBADD and PCI\_LCBDATA register pair.

Reading a register via the PCI\_LCBADD/PCI\_LCBDATA pair is done as follows:

- Write the following values into the PCI\_LCBADD register.
  - ADDRESS — The 18-bit register address. See below for the specific address per each register.
  - BLOCK\_ID — Defines the sub-unit where the register resides. Use the value 0x7F to access registers mentioned in this section.
  - LOCK — Use if need to gain access in case of multiple agents accessing the PCI\_LCBADD/PCI\_LCBDATA registers.
- Read the PCI\_LCBDATA register.

**Note:** Although PCI\_LCBDATA is a 32-bit register, the registers that maintain the actual count are read as atomic 64-bit reads. The PCI\_LCBADD contains the address of the low DW, and reading PCI\_LCBDATA returns a 64-bit value.

Writing a register via the PCI\_LCBADD/PCI\_LCBDATA pair is done as follows:

- Write the following values into the PCI\_LCBADD register.
  - ADDRESS — The 18-bit register address. See below for the specific address per each register.
  - BLOCK\_ID — Defines the sub-unit where the register resides. For actual values, consult the text below.
  - LOCK — Use if need to gain access in case of multiple agents accessing the PCI\_LCBADD/PCI\_LCBDATA registers.
- Write to the PCI\_LCBDATA register.

### 3.1.6.1 Event Counters - Transaction Layer

Counters operate in one of the following modes:

- **Count Mode** — The counter increments when the respective event occurred
- **Leaky Bucket Mode** — The counter increments only when the rate of events exceeded a certain value. See [Section 3.1.6.1.2](#) for more details.

The list of events supported by the X550 are listed in [Table 3-8](#).

**Table 3-8. PCIe Statistic Events Encoding**

| Events                          | Event Mapping (Hex) | Description                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Cycles                          | 0x00                | Increment on each PCIe clock tick                                                                                                                                                                                                                                                                                                                             |
| <b>Transaction Layer Events</b> |                     |                                                                                                                                                                                                                                                                                                                                                               |
| Bad Request TLPs                | 0x10                | Number of bad TLPs arriving to the transaction layer. These include: <ul style="list-style-type: none"> <li>• Request caused UR</li> <li>• Request caused CA</li> <li>• Malformed TLP</li> </ul>                                                                                                                                                              |
| Bad Completions                 | 0x11                | Number of bad Completions received. These include: <ul style="list-style-type: none"> <li>• Unexpected Completion</li> <li>• UR status</li> <li>• CA status</li> </ul>                                                                                                                                                                                        |
| Completion Timeout              | 0x12                | Number of completion timeout events                                                                                                                                                                                                                                                                                                                           |
| Poisoned TLP                    | 0x13                | Number of TLPs received with poisoned data                                                                                                                                                                                                                                                                                                                    |
| ECRC Check                      | 0x14                | Number of TLPs that fail ECRC check                                                                                                                                                                                                                                                                                                                           |
| <b>Link Layer Events</b>        |                     |                                                                                                                                                                                                                                                                                                                                                               |
| Retry Buffer Timeout            | 0x31                | Number of replay events that happen due to timeout (does not count replay initiated due to NACK)                                                                                                                                                                                                                                                              |
| Retry Buffer Replay Roll-Over   | 0x32                | Increment when a replay is initiated for more than 3 times                                                                                                                                                                                                                                                                                                    |
| <b>Physical Layer Events</b>    |                     |                                                                                                                                                                                                                                                                                                                                                               |
| Receive Error                   | 0x50                | Increment when one of the following occurs: <ol style="list-style-type: none"> <li>1. Decoder error occurred during training in the PHY. It is reported only when training ends.</li> <li>2. Decoder error occurred during link-up or till the end of the current packet (in case the link failed). This error is masked when entering/exiting EI.</li> </ol> |
| Surprise Link Down              | 0x51                | Increment when link is unpredictably down (Not because of reset or DFT)                                                                                                                                                                                                                                                                                       |

### 3.1.6.1.1 Count Mode

The following CSR fields control operation of the Count mode:

- Four 32-bit counters `PCI_GSCN_0_3` track events and increment on each occurrence of an event.
  - The four 32-bit counters can also operate in a two 64-bit mode to count long intervals or large payloads.
    - Registers `PCI_GSCN_0_3[0]` and `PCI_GSCN_0_3[1]` form the first 64-bit counter. Registers `PCI_GSCN_0_3[2]` and `PCI_GSCN_0_3[3]` form the second 64-bit counter.
    - The `PCI_GSCL_1.GIO_64_BIT_EN` selects between 32-bit and 64-bit modes.
- The `PCI_GSCL_1.GIO_COUNT_EN_[3:0]` bits enable each of the 4 counters.
  - The enable bits for the two 64-bit counters are `PCI_GSCL_1.GIO_COUNT_EN_0` and `PCI_GSCL_1.GIO_COUNT_EN_2`, respectively.
- The `PCI_GSCL_1.GIO_COUNT_START` bit starts event counting of enabled counters.
- The `PCI_GSCL_1.GIO_COUNT_STOP` bit stops event counting of running counters.
- The `PCI_GSCL_1.GIO_COUNT_RESET` bit resets the event counters.
- The `PCI_GSCL_2` associates an event with each of the 4 counters.
  - In 64-bit mode, the `GIO_EVENT_NUM_[2,0]` fields are used.

### 3.1.6.1.2 Leaky Bucket Mode

Each of the counters can be configured independently to operate in a leaky bucket mode. When in leaky bucket mode, the following functionality is provided:

- One of four 16-bit Leaky Bucket Counters (LBC) is enabled via the `LBC_ENABLE_[3:0]` bits in the PCIe Statistic Control register #1.
- The LBC is controlled by the `GIO_COUNT_START`, `GIO_COUNT_STOP`, `GIO_COUNT_RESET` bits in the PCIe Statistic Control register #1.
- The LBC increments every time the respective event occurs.
- The LBC is decremented every  $T_{\mu s}$  as defined in the `LBC_TIMER_N` field in the PCIe Statistic Control registers #5...#8 (`PCI_GSCL_5_8`).
- When an event occurs and the value of the LBC meets or exceeds the threshold defined in the `LBC_THRESHOLD_N` field in the PCIe Statistic Control registers #5...#8 (`PCI_GSCL_5_8`), the respective statistics counter increments, and the LBC counter is cleared to zero.

## 3.1.6.2 Event Counters - Link and Physical Layers

This section describes the performance events for the Link and Physical layers and how to manage the counters associated with these events.

**Note:** Before using LCB performance counters, the clock gating should be disabled by setting the `PCIE_CLKGATE_DIS` field in the `PCI_GLBL_CNF` register.

The registers responsible for the Link and Physical layers counters are accessed via the `PCI_LCBADD` and `PCI_LCBDATA` register pair.

Two events can be counted concurrently. The event counters include two sets of registers, each managing one event counter. Such pairs are documents as `<register_name>[1:0]`.

The following procedures manage the operation of the event counters (when writing to part of the register, make sure other fields are written with their existing values):

- Resetting the counters configuration:
  - Set the XPPERFCON.GRST bit.
  - Clear the XPPERFCON.GRST bit (otherwise the logic stays in reset).
- Setting an event:
  - Write 0x0...0 to the XPPMCL[1:0] registers
  - Set the XPPMR[1:0].CENS field to 0x1
  - Set the XPPMR[1:0].CNTMD field to 0x1
  - Set the XPPMER[1:0].XPRSCA field to 0x1
  - Set the event according to [Table 3-9](#).
- Starting a count:
  - Set the XPPERFCON.GCE bit.
- Stopping a count:
  - Clear the XPPERFCON.GCE bit.
- Reading the count (note: reading the counter clears their values):
  - Read the respective XPPMDH[1:0] and XPPMDL[1:0] register pair in a single 64-bit aligned access.

[Table 3-9](#) defines the Link and Physical Layer events.

**Table 3-9. Link and Physical Layer Performance Events**

| Event                      | Description                                                                                                                                                            | Register Field          |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|
| Uncorrectable Errors       | Counts the total number of Uncorrectable Errors.                                                                                                                       | XPPMER[1:0].CNTUCERR    |
| Correctable Errors         | Counts the total number of Correctable Errors.                                                                                                                         | XPPMER[1:0].CNTCERR     |
| Tx L0s state utilization   | Counts the number of entries to L0s on the Tx lanes.                                                                                                                   | XPPMER[1:0].TXLOSU      |
| Rx L0s state utilization   | Counts the number of entries to L0s on the Rx lanes.                                                                                                                   | XPPMER[1:0].RXLOSU      |
| Link Utilization           | Counts clocks that a port is receiving data.<br>If one counter counts receiver errors and another counter counts Link Utilization, a bit error rate can be calculated. | XPPMER[1:0].LNKUTIL     |
| Recovery State Utilization | Counts the number of entries to Recovery state.                                                                                                                        | XPPMER[1:0].RECOVERY    |
| ASPM L1 state utilization  | Counts the number of entries to ASPM L1 state (i.e. initiated by the device).                                                                                          | XPPMER[1:0].L1          |
| SW L1 state utilization    | Counts the number of entries to L1 state initiated by software.                                                                                                        | XPPMER[1:0].SWL1        |
| Tx and Rx L0s utilization  | Counts number of events where both Tx and Rx are in L0s state.                                                                                                         | XPPMER[1:0].RXLOSTXLOSU |
| NAK DLLP received          | Counts number of received NAK DLLPs.                                                                                                                                   | XPPMER[1:0].NAKDLLP     |

### 3.1.6.3 Bandwidth Counters

The bandwidth counters measure total payload bytes transferred over the PCIe link. Counting is provided per each traffic type (posted, non-posted, completions) per direction (upstream, downstream).

The mechanisms described above hold for the bandwidth counters with the following differences:

- Setting an event:
  - Set the XPPMR[1:0].*CENS* field to 0x1.
  - Set the XPPMR[1:0].*EGS* field to 0x2.
  - Set the XPPMR[1:0].*FCCSEL* field to the desired traffic type (posted, non-posted, completions, or all).
  - Set the XPPMER[1:0].*TXRXSEL* field to desired values.
  - Set the XPPMER[1:0].*XPRSCA* field to 0x1.
  - Set the XPPERFCON.*GCE* field to 0x1.

Registers fields used exclusively by the bandwidth counters:

- XPPMR[1:0].*FCCSEL* — Selects the desired traffic type (posted, non-posted, completions, or all).
- XPPMER[1:0].*TXRXSEL* — Selects between monitoring downstream traffic, upstream traffic, or both.

#### 3.1.6.3.1 Register Map

The register fields that control the Link and Physical Layer events are as follows:

**Table 3-10. XP PM Compare Low Bits Register (XPPMCL[1:0]) (0x3288, 0x328C)**

| Field | Bit(s) | Init.    | Description                                                                        |
|-------|--------|----------|------------------------------------------------------------------------------------|
| CMPL  | 31:0   | 0xFF...F | <b>PM Compare Low Value</b><br>Low order bits [31:0] for PM compare register[1:0]. |

**Table 3-11. XP PM Data Low Bits Register (XPPMDL[1:0]) (0x32E8, 0x32F0)**

| Field | Bit(s) | Init.     | Description                                                                         |
|-------|--------|-----------|-------------------------------------------------------------------------------------|
| CNTL  | 31:0   | 0x00...00 | <b>PM Data Counter Low Value</b><br>Low order bits [31:0] for PM data counter[1:0]. |

**Note:** XPPMDL must be read together with the respective XPPMDH register as a single 64-bit aligned read. The registers are simultaneously cleared on read.

**Table 3-12. XP PM Data High Bits Register (XPPMDH[1:0]) (0x32EC, 0x32F4)**

| Field | Bit(s) | Init.   | Description                                                                            |
|-------|--------|---------|----------------------------------------------------------------------------------------|
| CNTH  | 3:0    | 0x0     | <b>PM Data Counter High Value</b><br>High order bits [35:32] for PM data counter[1:0]. |
| RSVD  | 31:4   | 0x0...0 | Reserved.                                                                              |

**Note:** XPPMDH must be read together with the respective XPPMDL register as a single 64-bit aligned read. The registers are simultaneously cleared on read.

**Table 3-13. XP PM Response Control Register (XPPMR[1:0]) (0x3294, 0x3298)**

| Field | Bit(s) | Init. | Description                  |
|-------|--------|-------|------------------------------|
| RSVD  | 10:0   | 0x0   | Reserved.                    |
| CENS  | 13:11  | 00b   | <b>Counter Enable Source</b> |
| CNTMD | 15:14  | 00b   | <b>Count Mode</b>            |
| EGS   | 20:19  | 00b   | <b>Event Group Selection</b> |
| RSVD  | 31:21  | 0x0   | Reserved.                    |

**Table 3-14. XP PM Resource Events Register (XPPMER[1:0]) (0x32AC, 0x32B0)**

| Field    | Bit(s) | Init. | Description                                                                                                                                                                                                                                       |
|----------|--------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TXRXSEL  | 1:0    | 00b   | <b>Tx/Rx Select</b><br>This field selects the traffic direction to monitor:<br>1xb = Transmit<br>x1b = Receive (from PCIe bus)<br>11b = Either Transmit or Receive direction.                                                                     |

### 3.1.6.4 Latency Counter

The latency counter measures the min, max, or average read latency.

**Note:** Completion Timeout events are ignored when the latency counter is enabled.

The latency counters are managed via a set of register fields described below (see also [Table 3-16](#), [Table 3-17](#), and [Table 3-18](#)). Each of the following sources of traffic has its separate set of registers and counters:

- 0x0 — Rx LAN descriptor fetch
- 0x1 — Tx LAN descriptor fetch
- 0x4 — Internal cache load
- 0x5 — Internal management engine read
- 0x6 — Tx LAN packet fetch

The registers are accessed via the PCI\_LCBADD and PCI\_LCBDATA registers.

The register fields that control the latency counter operation are:

**Table 3-16. NPQ Control Register - NPQC (0x00000)**

## 3.2 Management Interfaces

The X550 contains three possible interfaces to an external BMC.

- SMBus
- NC-SI (over RMII)
- MCTP (over PCIe or SMBus)

### 3.2.1 SMBus

SMBus is an optional interface for pass-through and/or configuration traffic between an external BMC and the X550. The SMBus channel behavior and the commands used to configure or read status from the X550 are described in [Section 11.5](#).

The X550 also enables reporting and controlling the device using the MCTP protocol over SMBus. The MCTP interface is used by the BMC to control the NIC and for pass-through traffic. All network ports are mapped to a single MCTP endpoint on SMBus. For information, refer to [Section 11.5](#).

#### 3.2.1.1 Channel Behavior

The SMBus specification defines a maximum frequency of 100 KHz. However, when acting as a slave, the X550 can receive transaction with a clock running at up to 1 MHz. When acting as a master, it can toggle the clock at 100 KHz, 400 KHz or 1 MHz. The speed used is set by the *SMBus Connection Speed* field in the *SMBus Notification Timeout and Flags* NVM word ([Section 6.5.4.3](#)).

## 3.3 Network Controller — Sideband Interface (NC-SI)

The NC-SI interface in the X550 is a connection to an external MC. It operates as a single interface with an external BMC, where all traffic between the X550 and the BMC flows through the interface.

The X550 NC-SI interface meets the NC-SI version 1.0.0 specification as a PHY-side device.

### 3.3.1 Electrical Characteristics

The X550 complies with the electrical characteristics defined in the NC-SI specification.

### 3.3.2 NC-SI Transactions

The NC-SI link supports both pass-through traffic between the BMC and the X550 LAN functions, as well as configuration traffic between the BMC and the X550 internal units as defined in the NC-SI protocol. Refer to [Section 11.6.2](#) for information.

### 3.3.3 MCTP (Over PCIe or SMBus)

The X550 supports MCTP protocol for management. MCTP runs over PCIe or SMBus. The X550 implements NC-SI over MCTP protocol for command and pass-through traffic. See [Section 11.7](#) for details.

## 3.4 Non-Volatile Memory (NVM)

### 3.4.1 General Overview

The X550 uses a Flash device to store product configuration information. The Flash is divided into three general regions:

- **Hardware Accessed** — Loaded by the the X550 hardware after power-up, PCI reset de-assertion, D3 to D0 transition, or software reset. Different hardware sections in the Flash are loaded at different events. For more details on power-up and reset sequences, see [Section 4.1](#) and [Section 4.2](#).
- **Firmware Area** — Includes firmware code and structures used by the firmware for management configuration in its different modes.
- **Software Accessed** — This region is used by software entities such as LAN drivers, option ROM software and tools, PCIe bus drivers, VPD software, etc.

#### 3.4.1.1 NVM Protection

The NVM protection method implemented in the X550 relies on an “authenticate on update” concept. It means that the protected modules are not authenticated after initialization, but prior to committing a module update operation only. NVM protection is guaranteed by an inductive authentication chain, that assumes an initial secured NVM image and requires that any NVM update must be secure as well. This method mandates the following limitations and restricting working assumptions:

1. An initial ‘good’ image is loaded into the flash at the manufacturing site which is assumed to be safe.
  - It assumes customers (OEM and end-user) know the source of the installed components, the supply chain producing these components is not compromised during manufacturing, and that the NIC/LOM is physically protected from modification after deployment.
  - The possibility exists that unauthorized firmware may be loaded into the NVM via physical modification post manufacturing, as well as through supply chain vulnerabilities. However, firmware updates via programmatic (software) methods are enhanced to require authentication prior to updating NVM settings. Furthermore, host software can independently detect whether the firmware image has an invalid digital signature.
2. In a normal operating mode, NVM write accesses are controlled by the device (firmware) and cannot be performed via the memory mapped accesses, EEWR register, or bit-banging. Memory mapped NVM access remains available for NVM read accesses only. For simplicity and flexibility reasons, NVM write accesses from the host can be initiated via host interface commands ([Section 11.8.3.3](#)), VPD write interface, or via a BMC command, which are all handled by firmware. Memory BAR writes, EEWR and FLA bit-banging accesses are blocked by hardware when the NVM is protected.

3. All the supported Flash parts share the same set of op-codes as described in [Section 3.4.1.2](#). A blank Flash programming mode is provided (besides the normal programming mode previously mentioned in item 2), where the Flash can be programmed directly without firmware involvement via the FLA bit-banging or Flash BAR interfaces. This mode is indicated by `FLA.LOCKED = 0b`.

### 3.4.1.2 Flash Device Requirements

The X550 supports Flash devices with a sector erase size of 4 KB and an address width of 24 bits (up to 4 MB). Note that many Flash vendors are using the term sector differently. This document uses the term Flash sector for a logic section of 4 KB.

The X550 supports Flash devices that are either write-protected by default after power-up or not. The X550 is responsible to remove the protection by sending the write-protection removal Op-Code to the Flash after power up.

The following Op-Codes are supported by the X550 as they are common to all supported Flash devices:

1. Write Enable (0x06)
2. Read Status Register (0x05) - used by hardware internally.
3. Write Status Register (0x01). The written data is 0x00 to cancel the Flash default protection. Used by hardware internally.
4. Read Data (0x03). Burst read is supported.
5. Byte Program (0x02). To program a data byte.
6. 4 KB Sector-Erase (0x20)
7. Chip-Erase (0xC7)
8. Read JEDEC ID (0x9F)

#### 3.4.1.2.1 Flash Identification

The Flash connected to the X550 can be identified by its JEDEC ID that can be read using the *Flash Info* host interface command ([Section 11.8.3.3.9](#)). This identification is available only if a valid Flash is installed. If the Flash is empty or with an invalid signature, software can read the JEDEC ID by applying an RDID command (opcode 0x9F) or a Read SFDP command (opcode 0x5A) via the bit-bang interface.

## 3.4.2 Shadow RAM

The first eight 4 KB sectors of the X550's Flash are allocated to create two 16 KB sections (section 0 and section 1), for the configuration content. At least one of these two sections must be valid at any given time or else the X550 is set to hardware default. Following a Power On Reset (POR), the X550 copies the valid section of the Flash device into an internal Shadow RAM. Any further read accesses of the software or firmware to the lower 16 KB addresses of the NVM (not through flash BAR) are directed to the internal Shadow RAM. Modifications made to the Shadow RAM content are copied by the X550 into the other 16 KB section of the NVM, circularly flipping the valid section between sections 0 and 1 in the NVM.

This mechanism provides the following advantages:

1. A way to protect the image-update procedure from power down events by establishing a double-image policy. See [Section 3.4.8.1](#) for a description of the double-image policy. It relies on having pointers to NVM modules stored in the NVM section mirrored in the internal Shadow RAM.

2. A way to ensure hardware auto-load during a PCIe reset event can be completed within PCIe timing constraints (100 ms), even if the Flash is busy performing an erase operation initiated prior to that reset event.

Figure 3-6 shows the Shadow RAM mapping and interface.

**Figure 3-6. NVM Shadow RAM**

### 3.4.2.1 Shadow RAM Update Flow

Following a write access by the software device driver to update the Shadow RAM, the data should be updated in the Flash as well. The X550 updates the Flash from the Shadow RAM when software explicitly requests to update the Flash using the Shadow RAM Dump host interface command (Section 11.8.3.3.8). To reduce Flash update operations, software is expected to request a dump only once its last Shadow RAM update access completes. The X550 then copies the content of the Shadow RAM to the non valid configuration section and makes it the valid one.

### 3.4.3 NVM Clients and Interfaces

There are different software clients that can access the NVM: driver, tools, BIOS, VPD, etc.

Table 3-20 lists the different accesses to the NVM.

Table 3-20. Clients and Access Types to the NVM

| Client               | NVM Access Method (Data Width)                               | NVM Access Target | Logical Byte Address Range | NVM Access Interface                                           | Protection and Enforcement                                                                                                                                                                                                                          |
|----------------------|--------------------------------------------------------------|-------------------|----------------------------|----------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Software        | Memory BAR (parallel 32-bit)                                 | Flash             | 0x000000 - 0xFFFFFFFF      | Memory mapped read/write via BARs.                             | Write access is limited to a single byte, and is allowed only if hardware protection is disabled (FLA.LOCKED = 0).                                                                                                                                  |
|                      | FLA bit-banging (serial 1-bit)                               | Flash             | 0x000000 - 0xFFFFFFFF      | Software accesses to Flash by toggling the SPI pins.           | FLA interface access is available only if hardware protection is disabled (FLA.LOCKED = 0).                                                                                                                                                         |
|                      | Host interface Shadow RAM Read/Write command                 | Shadow RAM        | 0x000000 - 0x003FFF        | Access to Shadow RAM through the Shadow RAM Read/Write command | Requires a valid firmware image. Write protection is enforced by firmware.                                                                                                                                                                          |
|                      | Host interface Flash read command                            | Flash             | 0x000000 - 0xFFFFFFFF      | Software read from Flash via Flash Read command.               | Requires a valid firmware image.                                                                                                                                                                                                                    |
|                      | Host interface Flash write command/Flash block erase command | Flash             | 0x008000 - 0xFFFFFFFF      | Software write to sector/Flash erase                           | Requires a valid firmware image. Writes to protected areas are dropped when protection (enforced by firmware) is enabled. Protected sector erase or a complete Flash erase requests are rejected when protection (enforced by firmware) is enabled. |
|                      | VPD access (parallel 32-bit)                                 | Shadow RAM        | 0x000000 - 0x0003FF        | VPD Address and Data registers.                                | Write accesses are enabled to the R/W area of the VPD<br>If the VPD structure is not valid, the entire 1024 bytes area is RO.                                                                                                                       |
| Firmware or Software | FLMNG Parallel (Read: 32-bits Write: 8-bits)                 | Flash             | 0x000000 - 0xFFFFFFFF      | FLMNGCTL and FLMNGDATA registers accesses to the FLASH         | Software access is available only when protection is disabled.                                                                                                                                                                                      |

### 3.4.3.1 Memory Mapped Host Interface

Using the legacy Flash transactions, the Flash is accessed by the X550 each time the host CPU performs a read or a write operation to a memory location mapped to the Flash address space, or upon boot via accesses in the space indicated by the Expansion ROM Base Address register. Accesses to the Flash are based on a direct decode of CPU accesses to a memory window defined in either:

- Memory CSR + Flash Base Address Register (PCIe Control Register at offset 0x10).
- The Expansion ROM Base Address Register (PCIe Control Register at offset 0x30).
- The X550 is responsible to map accesses via the Expansion ROM BAR to the physical NVM. The offset in the NVM of the Expansion ROM module is defined by the *PCIe Expansion/Option ROM Pointer* (NVM word address 0x05). This pointer is loaded by the X550 from the NVM before enabling any access to the Expansion ROM memory space.

The X550 controls accesses to the Flash when it decodes a valid access. Attempt to out of range read access the PCIe Expansion/Option ROM module (according to *NVM Size* field in *NVM Control Word 1*) would return a value of 0xDEADBEEF. Attempt to memory-mapped write accesses to the Flash when protection is enabled or via expansion ROM BAR are ignored.

### 3.4.4 Flash Access Contention

Flash accesses initiated through different LAN functions might occur concurrently. The X550 does not synchronize between entities accessing the Flash, so a contention caused from one entity reading and another modifying the same location is possible.

To avoid such contention between software LANs or between software and firmware accesses, these entities are required to make use of the semaphore registers. Refer to [Section 11.8.4](#). Any read or write access to the NVM made by software/firmware must be preceded by acquiring ownership over the NVM. This is also useful to avoid the time out of a PCIe transaction made to a memory mapped Flash address while the Flash is busy performing a sector erase operation.

However, two software entities cannot use this semaphore mechanism: BIOS access through expansion ROM and VPD software.

- Since VPD software accesses only the VPD module, which is located in the configuration section of the NVM, VPD accesses are always performed against the Shadow RAM. Firmware must take NVM ownership before dumping the VPD changes to the Flash. The Shadow RAM dump sequence is described in [Section 3.4.2.1](#).
- No contention can occur between the BIOS access through expansion ROM and other software entities (including VPD) as it accesses the NVM while the operating system is down.
- Contentions between BIOS and firmware can however happen if a system reboot occurs while the MC is accessing the NVM.
  - If a system reboot is caused by a user pressing the standby button, it is required to route the wake-up signal from the standby button to the MC and not to the chipset. The MC issues a system reboot signal to the chipset only after the NVM write access completes. Firmware is responsible to respond with a "busy" error code to MC NC-SI commands while other NVM writes are in progress.
  - If a system reboot is issued by a local user on the host, there is no technical way to prevent NVM access contentions between the BIOS and the MC.

**Caution:** It is the user's responsibility when remotely accessing the NVM via the MC, to make sure another user is not currently initiating a local host reboot.

**Notes:** The PHY auto-load process from the Flash device is made up of short read bursts (32-bits) that can be inserted by hardware in between other NVM clients' accesses, at the lowest priority. It is the user's responsibility to avoid initiating a PHY auto-load while updating the PHY NVM modules.

The MAC auto-load from the Flash device itself occurs after power-up only, before host or firmware can attempt to access the Flash. The host must wait until PCIe reset is de-asserted (after ~1 second, which is enough time for the MAC auto-load to complete), and firmware starts its auto-load after the `EEC.MNG_READY` bit is asserted by hardware.

Other MAC auto-load events are performed from the internal Shadow RAM and do not compete with memory mapped accesses to the Flash device. During such MAC auto-loads, accesses from other clients via EEPROM-Mode registers are delayed until the auto-load process completes.

Software and firmware should avoid holding Flash ownership (via the dedicated semaphore bit) for more than 500 ms.

### 3.4.4.1 Flash Deadlock Avoidance

The Flash is a shared resource between the following clients:

1. Hardware auto-load of Shadow RAM (at power up).
2. LAN port 0 and LAN port 1 software accesses.
3. Manageability/firmware accesses.
4. Software tools.

All clients can access the Flash using parallel access. Hardware implements the actual access to the Flash. Hardware arbitrates between the different clients and schedules these accesses, avoiding starvation of any client.

However, the software and firmware clients can access the Flash using bit-banging. In this case, there is a request/grant mechanism that locks the Flash to the exclusive use of one client. If one client is stuck without releasing the lock, the other clients can no longer access the Flash. To avoid this deadlock, the X550 implements a time-out mechanism, which revokes the grant from a client that does not toggle the Flash bit-bang interface (FLA.FL\_SCK bit) for more than 2 seconds. If any client fails to release the Flash interface, hardware clears its grant, enabling the other clients to use the interface.

The deadlock timeout mechanism is enabled by the *Deadlock Timeout Enable* bit in *NVM Control Word 2* in the Flash.

### 3.4.5 Signature Field

The only way the X550 can tell if a Flash is present is by trying to read the Flash. The X550 first reads the Control word at word address 0x0 and at word address 0x2000. It then checks the signature value at bits 7 and 6 in both addresses.

If bit 7 is 0b and bit 6 is 1b in (at least) one of the two addresses, it considers the Flash to be present and valid. It then reads the additional Flash words from that section and programs its internal registers based on the values read. Otherwise, it ignores the values read from that location and does not read additional words.

If the signature bits are valid at both addresses the X550 assumes that the first section is the valid one.

### 3.4.6 VPD Support

The Flash image can contain an area for VPD. This area is managed by the OEM vendor and does not influence the behavior of hardware. Word 0x2F of the Flash image contains a pointer to the VPD area in the Flash. A value of 0xFFFF means VPD is not supported and the *PCI\_CAPCTRL.VPD\_EN* bit should be cleared in the PCI NVM section ([Section 6.4.5](#)), to prevent the VPD capability from appearing in the configuration space.

The maximal area size is 1024 bytes but can be smaller. The VPD block is built from a list of resources. A resource can be either large or small. The structure of these resources are listed [Table 3-21](#) and [Table 3-22](#).

**Table 3-21. Small Resource Structure**

| Offset  | 0                                                                       | 1 – n |
|---------|-------------------------------------------------------------------------|-------|
| Content | Tag = 0xxx,xyyyb (Type = Small(0), Item Name = xxxx, length = yy bytes) | Data  |

**Table 3-22. Large Resource Structure**

| Offset  | 0                                                        | 1 – 2  | 3 – n |
|---------|----------------------------------------------------------|--------|-------|
| Content | Tag = 1xxx,xxxxb (Type = Large(1), Item Name = xxxxxxxx) | Length | Data  |

The X550 parses the VPD structure during the auto-load process following PCIe reset to detect the read only and read/write area boundaries. The X550 assumes the following VPD fields with the limitations listed:

**Table 3-23. VPD Structure**

| Tag  | Length (Bytes)              | Data       | Resource Description                                                   |
|------|-----------------------------|------------|------------------------------------------------------------------------|
| 0x82 | Length of identifier string | Identifier | Identifier string.                                                     |
| 0x90 | Length of RO area           | RO data    | VPD-R list containing one or more VPD keywords.                        |
| 0x91 | Length of RW area           | RW data    | VPD-W list containing one or more VPD keywords. This part is optional. |
| 0x78 | n/a                         | n/a        | End tag.                                                               |

**VPD structure limitations:**

- The structure should start with a Tag = 0x82. If the X550 does not detect a value of 0x82 in the first byte of the VPD area or the structure does not follow the description of [Table 3-23](#), it assumes the area is not programmed and the entire 1024 bytes area is read only.
- The RO area and RW area are both optional and can appear in any order. A single area is supported per tag type. Refer to Appendix I in the PCI 3.0 specification for details of the different tags.
- If a VPD-W tag is found, the area defined by its size is writable via the VPD structure.
- The structure should end with a Tag = 0x78. The tag must be word aligned.
- The VPD area can be accessed through the PCIe configuration space VPD capability structure listed in [Table 3-23](#). Write accesses to a read only area or any access to an offset outside of the VPD area via this structure are ignored.
- VPD area must be mapped in the first 16 KB section of the Flash mapped to the Shadow RAM.
- VPD software does not check the semaphores before attempting to access the Flash via dedicated VPD registers. Even if the Flash is owned by another entity, VPD software read access to the VPD area in the Flash might complete immediately since it is first performed against the Shadow RAM. However, VPD software write access might not complete immediately since the VPD changes are committed to the Flash device at the X550's initiative, once the other entity releases Flash ownership, which may take up to several seconds.

### 3.4.6.1 VPD Access Flows

#### 3.4.6.1.1 First VPD Area Programming

The VPD capability is exposed in the PCIe configuration space only if the *PCI\_CAPCTRL.VPD\_EN* bit is set, regardless of any other sanity checks that are performed on the VPD area contents.

The VPD content and pointer can be written on a blank Flash without any limitation, such as for any other NVM module when in the blank Flash programming mode. After protection is enabled, if *VPD Write Enable* bit in *NVM Control Word 1* is cleared, only the RW area of the VPD is writable and only via the VPD interface.

#### 3.4.6.1.2 VPD Area Update Flow

1. The host initiates a VPD write by programming the offset and data fields of the VPD capability register set, and then setting the capability's *Flag* bit. (bit 15 in VPD Address Register - 0xE2).
2. Firmware checks if the VPD write is allowed - it checks that the write offset falls within the VPD-RW area.
  - a. If writing is not allowed, firmware clears the VPD flag in the configuration space to notify the VPD software that the transaction completed, and then it exits the flow.
3. Firmware indicates VPD access completion by clearing the VPD flag in the configuration space.

**Note:** In case the Flash is occupied with a previous sector erase operation, or if NVM ownership is held by software, the completion indication ([Step 3](#)) might be delayed. Additional writes should not be attempted before the completion of [Step 3](#).

## 3.4.7 NVM Read, Write, and Erase Sequences

Refer to [Section 3.4.8.1](#) for the flow required to update secure NVM modules.

Any software flow described in this section must be preceded by taking NVM ownership via semaphores as described in [Section 11.8.4](#).

### 3.4.7.1 Flash Block Erase Flow by Software

1. Send a Flash Block Erase host interface command ([Section 11.8.3.3.7](#)) with the aligned address of the block to erase.
2. Wait for the command to complete before releasing the NVM semaphore.

### 3.4.7.2 X550 Software Flow to the Bit-Banging Interface

To directly access the Flash when Flash is blank or not protected, software should follow these steps:

1. Write a 1b to the *Flash Request* bit (FLA.FL\_REQ).
2. Poll the *Flash Grant* bit (FLA.FL\_GNT) until it becomes 1b. It remains 0b as long as there are other accesses to the Flash.
3. Write or read the Flash using the direct access to the 4-wire interface as defined in the FLA register. The exact protocol used depends on the Flash placed on the board.

4. Write a 0b to the *Flash Request* bit (FLA.FL\_REQ).
5. Following a write or erase instruction, software should clear the *Request* bit only after it has checked that the cycles were completed by the NVM. This can be checked by reading the *BUSY* bit in the Flash device STATUS register. Refer to Flash data sheet for the op-code to be used for reading the STATUS register.

**Note:** The bit-banging interface is blocked during normal operation (protection enabled). Software should use the Host Interface commands. The firmware can use this interface all the time.

### 3.4.7.3 Erase Flow Using the FLA Register

To directly erase a sector in the Flash when Flash is blank or not protected, software should follow these steps:

1. Take ownership of NVM semaphore.
2. Set the *Flash Address* (FLA.FL\_ADDR) to the index of the 4 KB sector to erase and *Sector Erase* bit (FLA.FL\_SER) bit.
3. Read the FLA register until *Flash Busy* bit (FLA.FL\_BUSY) is cleared.
4. Release ownership of NVM semaphore.

To directly erase the entire Flash when Flash is blank or not protected, software should follow these steps:

1. Take ownership of NVM semaphore
2. Set *Device Erase* bit (FLA.FL\_DER) bit.
3. Read the FLA register until *Flash Busy* bit (FLA.FL\_BUSY) is cleared.
4. Release ownership of NVM semaphore.

### 3.4.7.4 Software Access Flow to Shadow RAM

#### 3.4.7.4.1 Read Interface

Software can read from the Shadow RAM using the following flow:

1. Send a Shadow RAM Read host interface command ([Section 11.8.3.3.2](#)) with the address and length to read.
2. Wait for the command to complete.
3. Read the data from the response buffer.

#### 3.4.7.4.2 Write Interface

Software can write to the Shadow RAM using the following flow:

1. Send a Shadow RAM Write host interface command ([Section 11.8.3.3.4](#)) with the address, length and data to write.
2. Wait for the command to complete.

### 3.4.7.5 Software Access to Flash via Memory Mapped Interface

#### 3.4.7.5.1 Read Access

Software can always use the Flash BAR for read accesses.

**Note:** Software should take semaphore ownership before executing the flow.

#### 3.4.7.5.2 Write Access

When Flash is blank or protection is disabled, software might initiate a write cycle via the Flash BAR as follows:

1. Take semaphore ownership before executing the flow.
2. Write the data byte to the Flash through the Flash BAR.
3. Poll the *FL\_BUSY* flag in the FLA register until cleared.
4. Repeat [Step 2](#) and [Step 3](#) to write additional bytes.
5. Release NVM semaphore ownership

As a response, hardware executes the following steps for each write access:

1. Set the *FL\_BUSY* bit in the FLA register.
2. Initiate autonomous write enable instruction.
3. Initiate the program instruction right after the enable instruction.
4. Poll the Flash status until programming completes.
5. Clear the *FL\_BUSY* bit in the FLA register.

**Note:** Software must erase the sector prior to programming it.

### 3.4.7.6 Software Flash Programming via Host Interface Command

Software must take semaphore ownership before executing the flow.

Software can write to non write protected areas of the flash using the following flow:

1. Send a *Flash Write* host Interface command ([Section 11.8.3.3.3](#)) with the address, length and data to write.
2. Wait for the command to complete.

### 3.4.7.7 Software Flash Read via Host Interface Command

Software must take semaphore ownership before executing the flow.

Software can read from the flash using the following flow:

1. Send a *Flash Read* host Interface command ([Section 11.8.3.3.1](#)) with the address and length of the data to read.
2. Wait for the command to complete.
3. Read the data from the completion of the command.

## 3.4.8 Extended NVM Flows

### 3.4.8.1 Flow for Updating Secured Modules

This section describes the flow to use to update the firmware image ([Section 6.5.7](#)), Option ROM ([Section 6.6](#)) or PHY module ([Section 6.7](#)).

To protect the Flash update procedure from power-down events, a double image policy is used for each of the updated modules. The software flow to update a module is as follows:

1. Take ownership over the NVM via the semaphore bits. Refer to [Section 11.8.4](#).
  - a. If `SW_FW_SYNC.NVM_UPDATE_STARTED` bit is read as clear, set this bit together with setting NVM semaphore bit. It is used to notify other entities that a long NVM update process which may take up to several minutes has started. During this time, other entities can not perform a write access to the firmware or PHY modules, but reading these modules in between update write bursts is allowed using the flash memory mapping. Legacy EEPROM Modules are not concerned by this limitation.
  - b. Otherwise, release NVM semaphore ownership and restart the update process later on.
2. Read the pointer to the free provisioning area (NVM word 0x40). Check that the free provisioning area size read from NVM word 0x41 is greater or equal to the size of the new firmware/PXE/PHY image to be loaded in NVM.
  - a. If not, release NVM semaphore ownership, clear the `SW_FW_SYNC.NVM_UPDATE_STARTED` bit and exit the flow.
3. Initiate sector erase instructions ([Section 3.4.7.1](#)) to the entire free space provisioning segment.
  - a. To guarantee NVM semaphore ownership time does not exceed the 1 sec timeout, it is recommended to perform at this step no more than four 4 KB sector erase operations at once in a burst, releasing semaphore ownership for 200  $\mu$ s in between. This way, other entities can insert NVM read accesses in between burst without waiting for the entire update process completion, which might take minutes.
4. Write the new firmware/Option ROM/PHY module to the free provisioning area via Flash-mode access.
  - a. Same as [Step 3a](#), it is recommended to write at this step no more than four 4 KB sectors at once in a burst, releasing semaphore ownership for 200  $\mu$ s in between.

5. Send a Flash Module Update host Interface command ([Section 11.8.3.3.5](#)) with the module ID of the section to update. The encoding of the modules is:

| Module                     | ID       | Reference                     |
|----------------------------|----------|-------------------------------|
| Firmware code              | 0x1      | <a href="#">Section 6.5.7</a> |
| Reserved                   | 0x2      |                               |
| Reserved                   | 0x3      |                               |
| Reserved                   | 0x4      |                               |
| PHY Firmware Image         | 0x5      | <a href="#">Section 6.7</a>   |
| Reserved                   | 0x6-0xFD |                               |
| Option ROM                 | 0xFE     | <a href="#">Section 6.6</a>   |
| Reserved (Full Shadow RAM) | 0xFF     |                               |

6. Release the NVM semaphore and clear the SW\_FW\_SYNC.NVM\_UPDATE\_STARTED bit.
- Software must avoid taking the NVM semaphore again until the firmware command has completed. Any attempt to write the NVM until then is not performed by the device.
7. Firmware swaps between the Free Provisioning Area Pointer (word 0x40) and the Firmware Code Module pointer, PXE module pointer or the PHY pointer located at the Shadow RAM word address 0x3A/0x5/0x4 respectively
8. Software waits for the command to complete.
- If the update process failed due to a security check failure or a flash write fault, an *Authentication Error* (0x80) or *Data Error* (0x6) respectively is returned. Software must then exit the flow, prior to attempt another update.
9. If the updated module is the PHY image, the PHY should be instructed to reload the image using the following flow:
- Update the PHY firmware version number at NVM word address 0x19 ([Section 6.3.4.2](#)) using the Legacy EEPROM Module Update flow ([Section 3.4.7.6](#)).
  - Read-modify-write SRAMREL register for setting *LATCH\_IMAGE\_VLD* bit to 1b.
  - Read-modify-write SRAMREL register for setting *LATCH\_IMAGE\_VLD* bit to 0b.
  - Write PHY register bit 1E.C474.0 bit to 0b.
  - Force PHY image reload by setting PHY register bit 1E.C442.0 to 1b.
10. If the updated module is the firmware image, the firmware should be instructed to reload the image using the *Apply Update* command ([Section 11.8.3.3.6](#)).

### 3.4.8.2 Flow for Updating One of the RW Legacy EEPROM Modules

When updating one or several fields from a legacy EEPROM module there is a risk that a hardware auto-load event occurs in the middle of the operation (for example, due to a sudden PCIe reset), leading to the auto-load of an invalid or inconsistent content from the internal Shadow RAM into the device registers or memory. Therefore unless the field(s) can be updated by a single EEPROM-mode access, the updating software must repeatedly use the following procedure for each legacy EEPROM module to be updated:

1. Take ownership over the NVM via semaphore bits. Refer to [Section 11.8.4](#).
2. Invalidate the pointer to the module to be modified by setting it to 0xFFFF using *Shadow RAM Write* command. This way, if a hardware auto-load of the module is attempted, the associated register defaults are loaded instead. Do not invalidate pointers to firmware modules, only to hardware auto-load modules.
3. Modify the contents of the module via *Shadow RAM Write* command.
4. Restore the pointers modified in [Step 2](#) via *Shadow RAM Write* command.
5. Compute and update the software checksum (word 0x3F) if the contents covered by the software checksum was modified.
6. Release the NVM semaphore.
7. Send a Shadow RAM dump command ([Section 11.8.3.3.8](#)) to ask the device firmware to load the internal Shadow RAM into the Flash.

**Note:** Depending on the modified RO items, a system reset is generally required for loading the modifications into the device.

### 3.4.9 NVM Authentication Procedure

NVM update integrity feature ensures that only Intel approved firmware code (or other protected NVM module) is able to be updated on the X550 devices after manufacturing. This procedure is performed whenever attempting to update one of the protected modules.

Integrity validation of NVM updates is provided by a digital signature. The digital signature is a SHA256 Hash computed over the protected content (long by 256-bits) which is then encrypted by a 2048-bits RSA encryption using an Intel private key. This digital signature is stored in the manifest in the NVM module image. Also stored in the manifest is the corresponding RSA modulus (public key) and RSA exponent to be used to decrypt the digital signature.

To verify the authenticity of the digital signature, firmware must first verify that the RSA Modulus and RSA Exponent fields in the new firmware image loaded are identical to those in the old firmware image. If the RSA Modulus and Exponent fields are the same, firmware decrypts the digital signature using the 2048-bit RSA Modulus and Exponent fields stored in the manifest of the old firmware image to extract the expected SHA256 Hash of content (stored hash). Firmware then performs an independent SHA256 Hash over the protected content (computed hash). If the stored hash matches the computed hash, the digital signature is accepted, and the NVM update is applied.

NVM updates are validated prior to invalidating the old NVM configuration, such that the old NVM configuration is still usable if the update fails to validate. After the new NVM is successfully verified, the updated image is committed to device flash.

**Figure 3-7. Sign & Verify Procedures for Authenticated NVM Modules**

### 3.4.9.1 Digital Signature Algorithm Details

As described the digital signature generation is a hash computation followed by an RSA encryption. This is performed within Intel as part of the NVM update image generation process and not performed by Intel software in the field, nor by the X550.

The different algorithms used are described in the following locations:

- PKCS #1 v2.1: RSA Cryptography Standard, RSA Laboratories, June 14, 2002  
[www.rsa.com](http://www.rsa.com)
- SHA family definition  
[http://csrc.nist.gov/publications/fips/fips180-3/fips180-3\\_final.pdf](http://csrc.nist.gov/publications/fips/fips180-3/fips180-3_final.pdf)
- SHA usage with digital signatures  
<http://csrc.nist.gov/publications/nistpubs/800-107/NIST-SP-800-107.pdf>
- SHA validation vectors  
<http://csrc.nist.gov/groups/STM/cavp/documents/shs/SHAVS.pdf>

## 3.5 Configurable I/O Pins — Software-Definable Pins (SDPs)

The X550 has four software-defined pins (SDP pins) per port that can be used for miscellaneous hardware or software-controllable purposes. Unless specified otherwise, these pins and their function are bound to a specific LAN device. The use, direction, and values of SDP pins are controlled and accessed by the Extended SDP Control (ESDP) register. To avoid signal contention, following power-up, all four pins are defined as input pins.

Some SDP pins have specific functionality:

- The default direction of the SDP pins is loaded from the *SDP Control* word in the NVM.
- The lower SDP pins (SDP0-SDP2) can also be configured for use as External Interrupt Sources (GPI). To act as GPI pins, the desired pins must be configured as inputs and enabled by the GPIE register. When enabled, an interrupt is asserted following a rising-edge detection of the input pin (rising-edge detection occurs by comparing values sampled at the internal clock rate, as opposed to an edge-detection circuit). When detected, a corresponding GPI interrupt is indicated in the EICR register.

**Note:** An SDP configured as output can also generate interrupts, but this is not a recommended configuration.

The bit mappings are shown in [Table 3-24](#) for clarity.

**Table 3-24. GPI to SDP Bit Mappings**

| SDP Pin to be Used as GPI | ESDP Field Settings |                         | Resulting EICR Bit (GPI) |
|---------------------------|---------------------|-------------------------|--------------------------|
|                           | Directionality      | Enable as GPI Interrupt |                          |
| 2                         | SDP2_IODIR          | SDP2_GPIEN              | 27                       |
| 1                         | SDP1_IODIR          | SDP1_GPIEN              | 26                       |
| 0                         | SDP0_IODIR          | SDP0_GPIEN              | 25                       |

- SDP1 pins can also be used to (electrically) disable both PCIe functions altogether. Also, if the MC is present, the MC-to-LAN path(s) remain fully functional. This PCIe-Function-Off mode is entered when SDP1 pin of a port is driven high while PE\_RST\_N is de-asserted. For correct capturing, it is therefore recommended to set SDP1 pins to their desired levels while the PE\_RST\_N pin is driven low and to maintain the setting on the (last) rising edge of PE\_RST\_N. This ability is enabled by setting bit 11 in *NVM Control Word 2* (global NVM offset 0x01 - [Section 6.4.2.2](#)).

**Note:** The PCIe-Function-Off is activated regardless of the SDP1 direction defined in the NVM SDP Control word.

- The lowest SDP pins (SDP0\_0) of port 0 can be used to encode the NC-SI package ID of the X550. This ability is enabled by setting bit 15 in *NC-SI Configuration 2* word (offset 0x05 - [Section 6.5.4.6](#)) of the NVM. The 3-bit package ID is encoded as follows: Package ID = {0, SDP0\_0, 0}.
- When the SDP pins are used as IEEE1588 auxiliary signals they can generate an interrupt on any transition (rising or falling edge), refer to [Section 7.7.4](#).
- A pair of SDPs can be used to create an I<sup>2</sup>C interface as described in [Section 3.5.1](#).

All SDP pins can be allocated to hardware functions. See more details on IEEE1588 auxiliary functionality in [Section 7.7.4](#) while I/O pins functionality are programmed by the TimeSync Auxiliary Control (TSAUXC) register.

If mapping of these SDP pins to a specific hardware function is not required, the pins can be used as general purpose software defined I/Os. For any of the function-specific usages, the SDP I/O pins should be set to native mode by software setting of the *SDPxxx\_NATIVE* bits in the ESDP register. Native mode in those SDP I/O pins, defines the pin functionality at inactive state (reset or power down) while behavior at active state is controlled by the software. The hardware functionality of these SDP I/O pins differs mainly by the active behavior controlled by software.

Table 3-25 summarize the setup required to achieve each of the possible SDP configurations.

**Table 3-25. SDP Settings**

| SDP | Usage                                               | NVM Setting                                                         | ESDP        |              |               |                |
|-----|-----------------------------------------------------|---------------------------------------------------------------------|-------------|--------------|---------------|----------------|
|     |                                                     |                                                                     | SDPx_NATIVE | SDPx_IODIR   | SDP1_Function | SDP23_function |
| 0   | SDP                                                 | N/A                                                                 | 0           | Input/Output | N/A           |                |
|     | NC-SI package ID (Port #0 only)                     | Bit 15 in <i>NC-SI Configuration 2</i> NVM word                     | 0           | Input        |               |                |
|     | 1588 functionality as defined by the TSSDP register | N/A                                                                 | 1           | Input/Output |               |                |
| 1   | SDP                                                 | N/A                                                                 | 0           | Input/Output | 0             | N/A            |
|     | PCI disable                                         | NVM Control Word 2, <i>SDP_FUNC_OFF_EN</i> bit                      | N/A         | N/A          | N/A           |                |
|     | 1588 functionality as defined by the TSSDP register | N/A                                                                 | 1           | Input/Output | 0             |                |
|     | Thermal Sensor                                      | TS NVM-based Mode Enable bit in the Common Firmware Parameters word | 0           | Output       | 1             |                |
|     | Reserved                                            | N/A                                                                 | 1           | N/A          | 1             |                |
| 2   | SDP                                                 | N/A                                                                 | 0           | Input/Output | N/A           | N/A            |
|     | 1588 functionality as defined by the TSSDP register |                                                                     | 1           | Input/Output |               | 0              |
|     | I <sup>2</sup> C clock                              |                                                                     | 1           | N/A          |               | 1              |
| 3   | SDP                                                 | N/A                                                                 | 0           | Input/Output | N/A           | N/A            |
|     | 1588 functionality as defined by the TSSDP register |                                                                     | 1           | Input/Output |               | 0              |
|     | I <sup>2</sup> C data                               |                                                                     | 1           | N/A          |               | 1              |

### 3.5.1 I<sup>2</sup>C Over SDP

The I<sup>2</sup>C usage of SDP pins is enabled by setting the *SDP23\_function* bit and the *SDP[23]\_NATIVE* bits to 1b in ESDP register. This relates to the SDPx\_2 and SDPx\_3 pins, which operate as I2C\_CLK and I2C\_DATA, respectively.

The I<sup>2</sup>C interface operates via the I2CCMD and I2CPARAMS register set. Since this register set can be used by either software or firmware in alternation, its ownership must be acquired/released via the semaphore ownership taking/release flows described in [Section 4.7](#).

The I<sup>2</sup>C interface can be used in two methods, a hardware based access, where the device initiate a transaction following a software device driver request via the I2CCMD register ([Section 8.2.2.1.16](#)) or a software controlled bit-banging using the I2CPARAMS register ([Section 8.2.2.1.17](#)).

#### 3.5.1.1 Hardware Based I<sup>2</sup>C Access

The following flows should be used to access an I<sup>2</sup>C register.

As part of device initialization, or anytime before the actual access, the following parameters should be set:

- I2CPARAMS.PHYADD — the address of the device to access.
- I2CPARAMS.ACCESS\_WIDTH — the width of the data to read or write (byte or word).

**Note:** The I2CPARAMS register should not be modified during an I<sup>2</sup>C transaction.

To execute a write access, the following steps should be done:

1. Check that register is ready: Poll I2CCMD.R bit until it is read as 1b.
2. Command — The I2CCMD register is initialized with the appropriate PHY register address in *REGADD* field, the data to write in the *DATA* field and the operation (write) to the *OP* field (0b).
  - a. If an interrupt is required, set the I2CCMD.I field
3. Check that command is done: Poll I2CCMD.R bit until it is read as 1b.
  - a. Check that no error is indicated in the I2CCMD.E field.

To execute a read access, the following steps should be done:

1. Check that register is ready: Poll I2CCMD.R bit until it is read as 1b.
2. Command — The I2CCMD register is initialized with the appropriate PHY register address in the *REGADD* field, and the operation (read) to the *OP* field (1b).
  - a. If an interrupt is required, set the I2CCMD.I field
3. Check that command is done: Poll I2CCMD.R bit until it is read as 1b.
  - a. Check that no error is indicated in the I2CCMD.E field.
4. Read the data returned from the I2CCMD.DATA field. If a byte access is done (I2CPARAMS.ACCESS\_WIDTH = 0), only DATA[7:0] is valid.

See [Section 3.5.1.3](#) below for the I<sup>2</sup>C commands supported when using the built in read and write commands. All the transactions uses a clock of 100 KHz. When using the bit-bang method any command can be given to the I<sup>2</sup>C device.

### 3.5.1.2 Bit-Bang Based I<sup>2</sup>C Access

In this mode, the software device driver controls the I<sup>2</sup>C interface directly using the *I2CPARAMS* register according to the following table:

| Pad                             | Field Controlling the Output Value | Field Reflecting the Input Value | Field Controlling the Output Enable Value <sup>1</sup> |
|---------------------------------|------------------------------------|----------------------------------|--------------------------------------------------------|
| SDPx_2 (I <sup>2</sup> C clock) | CLK_OUT                            | CLK_IN                           | CLK_OE_N                                               |
| SDPx_3 (I <sup>2</sup> C data)  | DATA_OUT                           | DATA_IN                          | DATA_OE_N                                              |

1. 0b = Pad is output. 1b = Pad is input.

### 3.5.1.3 Supported Commands

**Note:** The gray columns below denotes cycles driven by the I<sup>2</sup>C device. White columns denotes cycles driven by the X550.

When a word read command (*I2CPARAMS.ACCESS\_WIDTH* = 1b, *I2CCMD.OP* = 1b) is given the following sequence is done by the X550:

**Table 3-26. I<sup>2</sup>C Read Transaction - Dummy Write**

|   |                           |    |   |                           |   |  |
|---|---------------------------|----|---|---------------------------|---|--|
| 1 | 7                         | 1  | 1 | 8                         | 1 |  |

## 3.6 LEDs

The X550 implements four output drivers intended for driving external LED circuits per port. Each of the four LED outputs can be individually configured to select the particular event, state, or activity, which is indicated on that output. In addition, each LED can be individually configured for output polarity as well as for blinking versus non-blinking (steady-state) indication.

The configuration for LED outputs is specified via the LEDCTL register. Furthermore, the hardware-default configuration for all LED outputs can be specified via NVM fields ([Section 6.4.7.3](#)) thereby supporting LED displays configurable to a particular OEM preference.

Each of the four LED's can be configured to use one of a variety of sources for output indication. For more information on the MODE bits see LEDCTL register (see [Section 8.2.2.1.10](#)).

The *IVRT* bits enable the LED source to be inverted before being output or observed by the blink-control logic. LED outputs are assumed to normally be connected to the negative side (cathode) of an external LED.

The *BLINK* bits control whether the LED should be blinked (on for 200 ms, then off for 200 ms or 83 ms on and 83 ms off according to the `LEDCTL.GLOBAL_BLINK_MODE`) while the LED source is asserted. The blink control can be especially useful for ensuring that certain events, such as *ACTIVITY* indication, cause LED transitions, which are sufficiently visible by a human eye.

**Note:** The LINK/ACTIVITY mode functions slightly differently than others as it ignores the BLINK value. The LED is:

- Off if there is no LINK
- On if there is LINK and no ACTIVITY
- Blinks if there is LINK and ACTIVITY

The mapping in [Table 3-32](#) is used to specify the LED control source (MODE) for each LED output:

Table 3-32. LED Mapping

| MODE        | Selected Mode   | Source Indication                                                                                                                                         |
|-------------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0000b       | LINK_UP         | Asserted or blinking according to the <i>LEDx_BLINK</i> setting when any speed link is established and maintained.                                        |
| 0001b       | LINK_10G        | Asserted or blinking according to the <i>LEDx_BLINK</i> setting when a 10 Gb/s link is established and maintained.                                        |
| 0010b       | MAC_ACTIVITY    | Active when link is established and packets are being transmitted or received. In this mode, the <i>LEDx_BLINK</i> must be set.                           |
| 0011b       | FILTER_ACTIVITY | Active when link is established and packets are being transmitted or received that passed MAC filtering. In this mode, the <i>LEDx_BLINK</i> must be set. |
| 0100b       | LINK/ACTIVITY   | Asserted steady when link is established and there is no transmit or receive activity. Blinking when there is link and receive or Transmit activity.      |
| 0101b       | LINK_1G         | Asserted or blinking according to the <i>LEDx_BLINK</i> setting when a 1 Gb/s link is established and maintained.                                         |
| 0110b       | LINK_100        | Asserted or blinking according to the <i>LEDx_BLINK</i> setting when a 100 Mb/s link is established and maintained.                                       |
| 0111b       | LINK_2_5G       | Asserted or blinking according to the <i>LEDx_BLINK</i> setting when a 2.5 Gb/s link is established and maintained.                                       |
| 1000b       | LINK_5G         | Asserted or blinking according to the <i>LEDx_BLINK</i> setting when a 5 Gb/s link is established and maintained.                                         |
| 1001b:1101b | Reserved        | Reserved.                                                                                                                                                 |
| 1110b       | LED_ON          | Always asserted or blinking according to the <i>LEDx_BLINK</i> setting.                                                                                   |
| 1111b       | LED_OFF         | Always de-asserted.                                                                                                                                       |

## 3.7 Network Interface

### 3.7.1 Overview

The X550 provides dual-port network connectivity with copper media. Each port includes integrated MAC-PHY functionality and can be operated at either 10 GbE, 1 GbE, 5GBASE-T, 2.5GBASE-T, or 100BASE-T(X) link speed. In terms of functionality there is no primary and secondary port as each port can be enabled or disabled independently from the other, and they can be set at different link speeds.

The integrated PHYs support the following specifications:

- 10GBASE-T as per the IEEE 802.3an standard.
- 1000BASE-T and 100BASE-TX as per the IEEE 802.3 standard.
- 2.5 and 5 Gb/s as per the NBASE-T specification.

**Note:** The reader is assumed to be familiar with the specifications included in these standards, which is not overlapping with content of subsequent sections.

All MAC configuration is performed using Device Control registers mapped into system memory or I/O space; an internal MDIO/MDC interface, accessible via software, is used to configure the PHY operation.

## 3.7.2 Internal MDIO Interface

The X550 implements an internal IEEE 802.3 Management Data Input/Output Interface (MDIO Interface or MII Management Interface) between each MAC and its attached integrated PHY. This interface provides firmware and software the ability to monitor and control the state of the PHY. It provides indirect access to an internal set of addressable PHY registers. It complies with the new protocol defined by Clause 45 of IEEE 802.3 std. No backward compliance with Clause 22.

**Notes:** MDIO access to PHY registers must be operational from the time the PHY has completed its initialization once having read the PHY image from the NVM.

During internal PHY reset events where the MAC is not reset, PHY registers might not be accessible and the MDIO access does not complete.

Software is notified that PHY initialization and/or reset has completed by either polling or by PHY reset done interrupt (see [Section 3.7.3.4.4](#)).

The internal MDIO interface is accessed through registers MSCA and MSRWD. An access transaction to a single PHY register is performed by setting the MSCA.MDICMD bit to 1b after programming the appropriate fields in the MSCA and MSRWD registers. The MSCA.MDICMD bit is auto-cleared after the read or write transaction completes.

To execute a write access, the following steps should be done:

1. Address Cycle - Register MSCA is initialized with the appropriate PHY register address in *MDIADD DEVADD*, and *PORTADD* fields, the *OPCODE* field set to 00b and *MDICMD* bit set to 1b.
2. Poll MSCA.MDICMD bit until it is read as 0b.
3. Write Data Cycle - Data to be written is programmed in field MSRWD.MDIWRDATA.
4. Write Command Cycle - *OPCODE* field in the MSCA register is set to 01b for a write operation and the MSCA.MDICMD bit is set to 1b.
5. Wait for the MSCA.MDICMD bit to reset to 0b, which indicates that the transaction on the internal MDIO interface completed.

To execute a read access, the following steps should be done:

1. Address Cycle - Register MSCA is initialized with the appropriate PHY register address in *MDIADD DEVADD*, and *PORTADD* fields, the *OPCODE* field set to 00b and *MDICMD* bit set to 1b.
2. Poll MSCA.MDICMD bit until it is read as 0b.
3. Read Command Cycle - *OPCODE* field in the MSCA register is set to 11b for a read operation and the MSCA.MDICMD bit is set to 1b.
4. Wait for the MSCA.MDICMD bit to reset to 0b, which indicates that the transaction on the internal MDIO interface completed.
5. Read Data Cycle - Read the data in field MSRWD.MDIRDDATA.

**Notes:** A read-increment-address flow is performed if the *OPCODE* field is set to 10b in [Step 3](#). The address is increased internally once data is read at [Step 5](#) so that no address cycle is needed to perform a data read from the next address.

Before writing the MSCA register, make sure that the MDIO interface is ready to perform the transaction by reading MSCA.MDICMD as 0b.

## 3.7.3 Integrated Copper PHY Functionality

### 3.7.3.1 PHY Performance

#### 3.7.3.1.1 Reach

**Table 3-33. BER and Ranges vs. Link Speed and Cable Types**

| Speed      | Cable  | Committed Reach                  | Committed BER       |
|------------|--------|----------------------------------|---------------------|
| 10GBASE-T  | CAT-7  | Full reach: 100 m                | < 10 <sup>-12</sup> |
|            | CAT-6a | Full reach: 100 m                |                     |
|            | CAT-6a | Short reach: 30 m                |                     |
|            | CAT-6a | Jumper mode / direct attach: 1 m |                     |
|            | CAT-6  | 55 m                             |                     |
|            | CAT-5e | 1m                               |                     |
| 1000BASE-T | CAT-5e | Full reach: 100 m                | < 10 <sup>-10</sup> |
| 100BASE-TX | CAT-5e | Full reach: 100 m                | < 10 <sup>-8</sup>  |
| 2.5GBASE-T | CAT-5e | Full Reach: 100 m                | < 10 <sup>-12</sup> |
|            | CAT-6  | Full Reach: 100 m                |                     |
| 5GBASE-T   | CAT-5e | Full Reach: 100 m                | < 10 <sup>-12</sup> |
|            | CAT-6  | Full Reach: 100 m                |                     |

**Note:** Reaches specified in the table refer to real cable lengths and not to the IEEE standard model.

#### 3.7.3.1.2 MDI/Magnetics Spacing

The X550 supports a variable distance of from 1.5 to 4 inches with the magnetics.

#### 3.7.3.1.3 Cable Discharge

The X550 is capable of passing the Intel cable discharge test. Contact your Intel representative for more details.

### 3.7.3.2 Auto-Negotiation and Link Setup

Link configuration is always determined by PHY auto-negotiation with the link partner. The X550 does not support parallel detect 100BASE-TX.

The software device driver must intervene in cases where a successful link is not negotiated or the designer desires to manually configure the link. This can be the situation only if the link partner is a legacy 100BASE-TX device, which does not support auto-negotiation.

### 3.7.3.2.1 Automatic MDI Cross-Over and Lane Inversion

Twisted pair Ethernet PHYs must be correctly configured for MDI (no cross-over) or MDI-X (cross-over) operation to inter operate. This has historically been accomplished using special patch cables, magnetics pinouts or Printed Circuit Board (PCB) wiring. The PHY supports the automatic MDI/MDI-X configuration (like automatic cross-over detection) originally developed for 1000Base-T and standardized in IEEE 802.3 clause 40, at any link speed and also during auto-negotiation. Manual (non-automatic) MDI/MDI-X configuration is still possible via bits 1:0 of Auto-Negotiation Reserved Vendor Provisioning 1 register at address 7.C410.

In addition to supporting MDI/MDI-X, the PHY supports lane inversion (MDI swap) of the ABCD pairs to DCBA. It is useful for tab up or tab down RJ45 or integrated magnetics modules on the board. It is configurable via PHY register 1.E400.

**Figure 3-8. Cross-Over Function (7.C410.1:0 = 00b)**

### 3.7.3.2.2 Auto-Negotiation Process

The integrated copper PHY performs the auto-negotiation function. Auto-Negotiation provides a method for two link partners to exchange information in a systematic manner to establish a link configuration providing the highest common level of functionality supported by both partners. Once configured, the link partners exchange configuration information to resolve link settings such as:

- Speed: 100/1000 Mb/s or 10 Gb/s
- Link flow control operation (known as PAUSE operation)

**Notes:** When operating in Data Center Bridging (DCB) mode, generally, priority flow control is used instead of link flow control, and it is negotiated via higher layer protocol (DCBx protocol) and not via auto-negotiation. Refer to [Section 3.7.4](#).

Each PHY is capable of successfully auto-negotiating with any device that supports 100 Mb/s or higher Ethernet, regardless of its method of Power over Ethernet (PoE) detection.

The X550 supports only full duplex mode of operation at any speed.

PHY specific information required for establishing the link is also exchanged.

If link flow control is enabled in the X550, the settings for the desired flow control behavior must be set by software in the PHY registers and auto-negotiation is restarted. After auto-negotiation completes,

the software device driver must read the PHY registers to determine the resolved flow control behavior of the link and reflect these in the MAC register settings (FCCFG.TFCE and MFLCN.RFCE).

Once PHY auto-negotiation completes, the PHY asserts a link-up indication to the MAC that might notify software by an interrupt if the Link Status Change (LSC) interrupt is enabled. The resolved speed is also indicated by the PHY to the MAC. The status of both is directed to software via LINKS.LINK\_UP and LINKS.LINK\_SPEED bits.

### 3.7.3.2.2.1 Speed Resolution and Partner Presence

At the end of the auto-negotiation process, the link speed is automatically set to the highest common denominator between the abilities advertised by the link partners.

If there is no common denominator, the PHY asserts the *Device Present* bit (Auto-Negotiation Reserved Vendor Status 1: Address 7.C810, bit E) if it detected valid link pulses during auto-negotiation even though there is no common link speed with the link partner. This bit is valid only if auto-negotiation is enabled.

If the PHY training sequence cannot complete properly in spite of auto-negotiation completing, the PHY retries auto-negotiation for a programmable number of times (set by PHY register 7.C400: 3:0) before downshifting cyclically. Downshifting is enabled by PHY register 7.C400: 4. Automatic downshifting events are reported by the *Automatic Downshift* bit in PHY register 7.CC00.

### 3.7.3.2.2.2 Link Flow Control Resolution

Flow control is a function that is described in Clause 31 of the IEEE 802.3 standard. It allows congested nodes to pause traffic. Flow control is essentially a MAC-to-MAC function. PHYs indicate their MAC ability to implement flow control during auto-negotiation. These advertised abilities are controlled through two bits in the auto-negotiation registers (Auto-Negotiation Advertisement Register: Address 7.10), bits 5 and 6 for PAUSE and Asymmetric PAUSE, respectively.

After auto-negotiation, the link partner's flow control capabilities are indicated in Auto-Negotiation Link Partner Base Page Ability Register: Address 7.13, bits 5 and 6.

There are two forms of flow control that can be established via auto-negotiation: symmetric and asymmetric. Symmetric flow control was defined originally for point-to-point links; and asymmetric for hub-to-end-node connections. Symmetric flow control enables either node to flow-control the other. Asymmetric flow-control enables a repeater or switch to flow-control a DTE, but not vice versa.

Generally either symmetric PAUSE is used or PAUSE is disabled, even between a end-node and a switch.

Table 3-34 lists the intended operation for the various settings of ASM\_DIR and PAUSE. This information is provided for reference only; it is the responsibility of the software to implement the correct function. The PHY merely enables the two MACs to communicate their abilities to each other.

**Table 3-34. Pause and Asymmetric Pause Settings**

| Local and Remote<br>ASM_DIR Settings | Local Pause<br>Setting | Remote Pause<br>Setting | Result                                              |
|--------------------------------------|------------------------|-------------------------|-----------------------------------------------------|
| Both ASM_DIR = 1b                    | 1                      | 1                       | Symmetric — Either side can flow control the other. |
|                                      | 1                      | 0                       | Asymmetric — Remote can flow control local only.    |
|                                      | 0                      | 1                       | Asymmetric — Local can flow control remote.         |

|                                      | Either or both = 0     |                         | No flow control.                                    |

### 3.7.3.3 PHY Initialization

#### 3.7.3.3.1 PHY Boot

Each PHY has an Embedded Microprocessor (MCP). Each MCP has its own instruction RAM (IRAM) and Data RAM (DRAM). The MCP code/data segment and the PHY default configuration are fetched from the external Flash device, right after power-on reset and also per PHY MMD register set to force a reload (Global General Provisioning 3: Address 1E.C442, bit 0).

PHY access to the Flash device is controlled by the MAC. Assuming the PHY is granted by the MAC with back-to-back access to the Flash, the PHY initialization process should take less than 200 ms, at the end of which a PHY reset done interrupt is issued and/or reported in PHY register 1E.CC00.6.

Internal MDIO interface provides access to the PHY registers but it does not provide the software with the ability to overwrite the PHY image located in the NVM. MDIO access is done via dedicated MAC registers only.

The X550 maintains a CRC-16 (standard CCITT CRC  $x^{16} + x^{12} + x^5 + 1$ ) over the PHY image in the NVM, and checks this on NVM loads. Inversion of the CRC after calculation is not required. If a CRC error occurs, the PHY image is reloaded again. If an error also occurs on the second try, the PHY is stopped and a fatal interrupt is generated to the host.

Default configuration read from the Flash overrides the default register values of the PHY. The same MCP code/data segment is auto-loaded to both PHYs, but each PHY has its own default configuration.

MCP code/data segment and default configuration read from the Flash are stored into internal Shadow RAMs. At PHY reset events, which are either issued by software (Global Standard Control 1: Address 1E.0000, bit F) or internally by the MAC, there is a reset of the micro controller; however there is no reload of ISRAM/DSRAM from the Flash. The micro controller begins executing instructions out of internal memory loaded from the previous Flash load. The same stands for PHY registers, which retrieves their default values loaded from the previous Flash load.

#### 3.7.3.3.2 PHY Power-Up Operations

The integrated PHY is designed to perform the following operations at boot:

1. Power-up calibration of VCOs and power supplies.
2. Provision stored default values (from Flash into internal data RAM and then into PHY registers).
3. Calibration of the Analog Front-End (AFE).
4. Cable diagnostics.
5. Auto-negotiation.
6. Perform training (as required).
7. Verify error-free operation.
8. Enter steady state.

#### 3.7.3.3.3 PHY Reset

Each PHY protects its data RAM via parity bits and its code RAM via ECC. In the event data corruption is detected, a PHY fault interrupt is issued (see [Section 3.7.3.4.1](#)).

Each PHY supports a watchdog timer to detect a stuck micro controller. Upon failure, a PHY fault interrupt is issued as well. Watchdog timer is set to 5 seconds by default.

The PHY is also reset on the same occasions that MAC is reset, except on software reset events for which the PHY does not get reset. A dedicated PHY reset command is provided to software instead, via a PHY register (Global Standard Control 1: Address 1E.0, bit F). Refer to [Table 4-5](#).

At PHY reset events, all the PHY functionality goes to reset including the micro controller except the PHY PLLs that go to reset only at power-up.

PHY reset completion is expected to take up to 5 ms, with no MDIO access during that time. PHY reset event causes link failure, which can take up to several seconds for resuming via auto-negotiation.

### 3.7.3.4 PHY Interrupts

The interrupt structure of each internal PHY is hierarchical in nature, and allows masking of all interrupts, at each of the levels of the hierarchy. The PHY has two interrupt hierarchies one is fully clause 45 compliant, the other is vendor defined, which is intended to allow determining the cause of an interrupt with only two status reads.

The values of these interrupt masks are visible via the internal MDIO interface in the vendor specific areas of each MMD, and the global summary register is located in the vendor specific area of the PHY registers (Global PHY Standard Interrupt Flags: Addresses 1E.FC00 and Global PHY Vendor Interrupt Flags: Addresses 1E.FC01).

The interrupt structure of each PHY is such that all standards-based interrupts can be read and cleared using a maximum of two PHY register reads.

There are two types of PHY interrupts according to their severity, normal or fatal:

- Fatal PHY interrupts are reported together with other fatal interrupts by the *ECC* bit in the EICR register. They concern the following events:
  - ECC error when reading PHY micro controller code
  - CRC error on the second attempt to load the PHY image from the NVM
  - PHY micro controller watchdog failure
- Normal PHY interrupts are reported by the *PHY\_GLOBAL\_INTERRUPT* bit in EICR register. They concern all other PHY interrupt causes.

**Note:** The PHY micro controller never resets itself to a fatal interrupt or to any other event. The host is responsible to reset the link in such situations. The link is down until then.

Many of the interrupt causes are mostly useful to debug the PHY hardware. Therefore, they are masked by default and unless a specific need arises should remain so.

By default, Link State Change and Global Fault are the only interrupts that should be unmasked by software. To enable them software should set the following bits:

- 1E.FF01.C and 1E.FF01.2 — PHY vendor mask
- 1E.D400.4 — Enable chip fault interrupt
- 1E.FF00.8 — Enable standard autoneg interrupt 1

Additionally, software can enable an interrupt on reset complete:

- 1E.D400.6 — Enable reset done interrupt

### 3.7.3.4.1 PHY Fault Interrupt

In the event of a PHY fatal error, 1E.CC00.4 is set and an error code is written to 1E.C850. Software should log this code and attempt to reset the PHY.

Among others, a fatal interrupt is generated on one of the following events:

- CRC error over the PHY image when trying to load it from Flash twice without success
- ECC error on one of the PHY's internal memory that contains control data
- Watchdog failure of the PHY embedded micro controller

In reaction to a fatal error, the MAC drops the link until the fatal error is cleared. Software is therefore required to reset the link (not only the PHY) and retry to reload the PHY firmware as described in [Section 3.7.3.4.2](#).

If three fatal PHY interrupts are handled with no link-up event in between, the link is considered to be down and the port must be disabled.

### 3.7.3.4.2 PHY Firmware Reload Flow

First read is 1E.FC00.0 = Vendor Alarm, followed by 1E.FC01, checking for bits 2 and 0 (Global Alarms 1 and 3 respectively) being set.

1. If any of them is set, check the following bits:

- 1E.CC02.0 *Watchdog Timer Alarm*
- 1E.CC00.4 *Device Fault* alarm (DRAM/IRAM non-correctable parity error)
- 1E.CC02.A *DRAM Parity Error* alarm
- 1E.CC02.9 Multi-bits *IRAM Parity Error* alarm; errors not corrected.
- If any of them is set, initiate daisy-chain reload on the PHY that is corrupted by setting 1E.C442.0.
- Wait for PHY interrupt and check that the reset is done by reading PHY register 1.CC02 and checking that bit 0 (*Reset Complete*) is set.
- Resume normal operation.

### 3.7.3.4.3 Link State Change Interrupt

When an interrupt is caused by a change in the link state, bit 7.1.2 is latching low. The actual link state can be found in register 1.E800.0.

**Table 3-35. PHY Link State Registers**

| Register Bits | Name                  | Description                                                               |
|---------------|-----------------------|---------------------------------------------------------------------------|
| 7.C800 2:1    | Connect Rate          | 0x0 = Reserved<br>0x1 = 100BASE-TX<br>0x2 = 1000BASE-T<br>0x3 = 10GBASE-T |
| 7.C800 0      | Connect Type (Duplex) | 0b = Half<br>1b = Full                                                    |
| 7.C810 F      | Energy Detect         | 1b = Detected                                                             |

Table 3-35. PHY Link State Registers (Continued)

| Register Bits | Name                   | Description                                                                                                                                                                                                                                                                                                                                                    |
|---------------|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7.C800 E      | Far End Device Present | 1b = Present                                                                                                                                                                                                                                                                                                                                                   |
| 7.C800 D:9    | Connection State       | 0x00 = Inactive (such as low-power or high-impedance).<br>0x01 = Cable diagnostics.<br>0x02 = Auto-negotiation.<br>0x03 = Training (10 GbE and 1 GbE only).<br>0x04 = Connected.<br>0x05 = Fail (waiting to retry autoneg).<br>0x06 = Test Mode.<br>0x07 = Loopback Mode.<br>0x08 = Reserved.<br>0x09 = Reserved.<br>0x0A = Reserved.<br>0x0B:0x10 = Reserved. |

#### 3.7.3.4.4 Reset Done Interrupt

If software has enabled the reset done interrupt, such an event generates an interrupt, which is indicated by bit 1E.CC00.6 being set. Note that a boot complete event is simultaneous with the reset event.

#### 3.7.3.4.5 PHY Interrupt Handling Flow

Firmware is responsible to guarantee an operative PHY even when host is down or malfunctioning, to:

- Provide a remote access to MC from the network.
- Receive WoL packets.

When the host is down, interrupts from MAC blocks which are critical for MC/WoL are also handled by the firmware:

- ECC-Error from Security Rx/Tx blocks
- ECC-Error from Rx-Filter
- ECC-Error from DMA-Tx

##### 3.7.3.4.5.1 Firmware to Software PHY Interrupt Handling Coordination

**Note:** As the software device driver does not handle PHY interrupt events, the flow below is not implemented and is provided as a guideline if implemented in the future. The software device driver needs to handle PHY interrupts.

Firmware cannot be sure the host is well functioning and consequently it always handles PHY interrupts first. Once it has completed to do its handling of PHY interrupts, firmware sets the relevant EEMNGCTL.CFG\_DONE0/1 bit and notifies the host it can start its own handling by issuing EICR.MNG interrupt. Since the PHY interrupt flags are cleared by read, the following flow must be run by host and firmware whenever a PHY interrupt occurs:

1. Host does not attempt to take ownership over the PHY semaphore until *CFG\_DONE* bit is set by firmware.
  - In case the PHY semaphore is currently owned by the host, it stops accessing *PHYINT\_STATUS* or PHY registers and releases the PHY ownership as soon as possible. Refer to [Section 11.8.4](#) for the maximum semaphore ownership time allowed.
2. Firmware takes ownership of PHY semaphore
3. Firmware copies the PHY interrupt flags read from PHY registers into the *PHYINT\_STATUS* registers
  - When writing *PHYINT\_STATUS* registers firmware must not clear bits that were not cleared by the host yet
4. Firmware handles the PHY interrupt by resetting the PHY (only if it is a fatal PHY interrupt)
5. Firmware sets *CFG\_DONE* bit, releases ownership of the PHY semaphore, and issues *EICR.MNG* interrupt to host.
6. Host takes semaphore ownership over the PHY.
7. Host reads the *PHYINT\_STATUS* registers and clears them (by writing zeros).
8. Host handles the PHY interrupts.
  - Prior to doing a PHY re-configuration that might drop the link (e.g. restart auto-negotiation), the host must wait until the *VETO* bit is read as 0b.
9. Host releases PHY semaphore.

**Notes:** *CFG\_DONE* bits are set by firmware and cleared by software. They cannot be cleared by firmware, and cannot be set by software.

For simplifying drivers, firmware runs the above flow even if there is no MC or WoL. No wake-up of the host occurs for the fatal PHY events handled by firmware.

*PHYINT\_STATUS* registers and *EEMNGCTL.CFG\_DONE* bits are reset by hardware only at power-up events.

### 3.7.3.5 Cable Diagnostics

The PHY implements a powerful cable diagnostic algorithm to accurately measure all of the TDR and TDT sequences within the group of four channels. The algorithm used transmits a pseudo-noise sequence with an amplitude of less than 300 mV for a brief period of time during startup. From the results of this measurement, the length of each pair, the top four impairments along the pair, and the impedance of the cable are flagged. These measurements are accurate to  $\pm 1$  m under the assumption of the ISO 11801 cable propagation characteristics of 5.46 ns / m and are presented in the Global MMD register map.

Cable diagnostics performed by the PHY are listed in [Table 3-36](#) and apply to all operating rates and scenarios.

**Note:** The PHY does not distinguish more than one feature within 5 m, the dominant source of reflection can be recorded as a single feature.

Each PHY completes the TDR measurement within 5 seconds of activation from an MDIO accessible register bit (1E.C470[4]). The PHY indicates that the operation is complete using the *Connection State* field in *Auto-Negotiation Reserved Vendor Status 1* register (7.C810.[D:9]). The PHY completes the entire cable diagnostic functions following a single access from the host.

**Table 3-36. Proprietary Cable Diagnostics**

| Test                                         | Feature                                                                             | Notes            |
|----------------------------------------------|-------------------------------------------------------------------------------------|------------------|
| Distance to reflections: each of four pairs. | Distance to four reflection points for each pair.                                   | ±1 m resolution. |
|                                              | Un-terminated end point ( $>300\ \Omega$ ).                                         |                  |
|                                              | Terminated $> 115\ \Omega$ or mismatch.                                             |                  |
|                                              | Terminated $\approx 100\ \Omega$ or compliant connector (if reflection is visible). |                  |
|                                              | Terminated $< 85\ \Omega$ or mismatch.                                              |                  |
|                                              | Short circuit $< 30\ \Omega$ or mismatch.                                           |                  |
| Pair-to-pair short.                          | Distance to short.                                                                  |                  |
|                                              | Suspected pairs.                                                                    |                  |

Cable diagnostics is able to detect all simple shorts on a cable. If the short is from one pair to any other pair, it is necessary to indicate the detail of the pair-pair short connectivity. It is recommended to use a mechanism that includes sending a signal on one pair and listening on all pairs. If a reflection is detected (greater than the limit allowed for NEXT) on any pair other than the one with the signal, it can be assumed that this is due to an inter-pair short.

Each PHY performs cable diagnostics at startup, prior to attempting auto-negotiation. Manual re-running of diagnostics can also be initiated by setting bit 4 of Global Reserved Provisioning 1 register (1E.C470).

### 3.7.3.6 False Training Detection

Each PHY restricts the amplitude of the cable diagnostics sequence to be less than 300 mV to avoid false detection of the training sequence by a parallel detection auto-negotiation block.

### 3.7.3.7 Low Power Operation and Power Management

The PHY incorporates numerous features to maintain the lowest power possible. Refer to [Section 5.3.1](#).

## 3.7.4 Ethernet Flow Control (FC)

The X550 supports flow control as defined in 802.3x, as well as the specific operation of asymmetrical flow control defined by 802.3z. The X550 also supports Priority Flow Control (PFC), known as Class Based Flow Control, as part of the DCB architecture.

**Note:** The X550 can either be configured to receive regular FC packets or PFC packets. The X550 does not support receiving both types of packets simultaneously.

FC is implemented to reduce receive buffer overflows, which result in the dropping of received packets. FC also allows for local controlling of network congestion levels. This can be accomplished by sending an indication to a transmitting station of a nearly full receive buffer condition at a receiving station.

The implementation of asymmetric FC allows for one link partner to send FC packets while being allowed to ignore their reception. For example, not required to respond to PAUSE frames.

The following registers are defined for implementing FC. In DCB mode, some of the registers are duplicated replicated per Traffic Class (TC), up to eight duplicates copies of the registers. If DCB is disabled, index [0] of each register is used.

- MAC Flow Control Register (*MFLCN*) — Enables FC and passing of control packets to the host.
- Flow Control Configuration (*FCCFG*) — Determines mode for Tx FC (No FC vs. link-based vs. priority-based). Note that if Tx FC is enabled, Tx CRC by hardware should be enabled as well (*HLREG0.TXCRCEN* = 1b).
- Flow Control Source Address Low, High (*RAL*[0], *RAH*[0])
- Flow Control Destination Address Low, High (*FCAMACL*, *FCAMACH*) — 6-byte FC multicast address.
- Priority Flow Control Type Opcode (*PFCTOP*) — Contains the type and OpCode values for PFC.
- Flow Control Receive Threshold High (*FCRTH*[7:0]) — A set of 13-bit high watermarks indicating receive buffer fullness. A single watermark is used in link FC mode and up to eight watermarks are used in PFC mode.
- Flow Control Receive Threshold Low (*FCRTL*[7:0]) — A set of 13-bit low watermarks indicating receive buffer emptiness. A single watermark is used in link FC mode and up to eight watermarks are used in PFC mode.
- Flow Control Transmit Timer Value (*FCTTV*[3:0]) — A set of 16-bit timer values to include in transmitted PAUSE frame. A single timer is used in link FC mode and up to eight timers are used in PFC mode.
- Flow Control Refresh Threshold Value (*FCRTV*) — 16-bit PAUSE refresh threshold value (in legacy FC *FCRTV*[0] must be smaller than *FCTTV*[0]).

### 3.7.4.1 MAC Control Frames and Reception of Flow Control Packets

#### 3.7.4.1.1 MAC Control Frame — Other than FC

The IEEE specification reserved the Ethertype value of 0x8808 for MAC control frames, which are listed in [Table 3-37](#).

**Table 3-37. MAC Control Frame Format**

| Field                 | Description                                                                                                                                                                                                                                   |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DA                    | The <i>Destination Address</i> field can be an individual or multicast (including broadcast) address. Permitted values for the <i>Destination Address</i> field can be specified separately for a specific control OpCode such as FC packets. |
| SA                    | Port Ethernet MAC Address (six bytes).                                                                                                                                                                                                        |
| Type                  | 0x8808 (two bytes).                                                                                                                                                                                                                           |
| Opcode                | The MAC control OpCode indicates the MAC control function.                                                                                                                                                                                    |
| Parameters            | The MAC control <i>Parameters</i> field must contain MAC control OpCode-specific parameters. This field can contain none, one, or more parameters up to a maximum of <i>minFrameSize</i> = 20 bytes.                                          |
| Reserved field = 0x00 | The <i>Reserved</i> field is used when the MAC control parameters do not fill the fixed length MAC control frame.                                                                                                                             |
| CRC                   | Four bytes.                                                                                                                                                                                                                                   |

### 3.7.4.1.2 Structure of 802.3X FC Packets

802.3X FC packets are defined by the following three fields (see [Table 3-38](#)):

1. A match on the six-byte multicast address for MAC control frames or a match to the station address of the device (Receive Address Register 0). The 802.3x standard defines the MAC control frame multicast address as 01-80-C2-00-00-01.
2. A match on the *Type* field. The *Type* field in the FC packet is compared against an IEEE reserved value of 0x8808.
3. A match of the MAC control *Opcode* field has a value of 0x0001.

Frame-based FC differentiates XOFF from XON based on the value of the *PAUSE Timer* field. Non-zero values constitute XOFF frames while a value of zero constitutes an XON frame. Values in the *Timer* field are in units of pause quanta (such as slot time). A pause quanta lasts 64 byte times, which is converted into an absolute time duration according to the line speed.

**Note:** XON frame signals the cancellation of the pause from that was initiated by an XOFF frame. Pause for zero pause quanta.

**Table 3-38. 802.3X Packet Format**

| Field  | Description                          |
|--------|--------------------------------------|
| DA     | 01_80_C2_00_00_01 (6 bytes).         |
| SA     | Port Ethernet MAC Address (6 bytes). |
| Type   | 0x8808 (2 bytes).                    |
| Opcode | 0x0001 (2 bytes).                    |
| Time   | XXXX (2 bytes).                      |
| Pad    | 42 bytes.                            |
| CRC    | 4 bytes.                             |

### 3.7.4.1.3 Priority Flow Control

DCB introduces support for multiple TCs assigning different priorities and bandwidth per TC. Link-level Flow Control (PAUSE) stops all the TCs. Priority Flow Control (PFC), known as Class Based Flow Control or CBFC, allows more granular Flow Control on the Ethernet link in a DCB environment as opposed to the PAUSE mechanism defined in 802.3X.

PFC is implemented to prevent the possibility of receive packet buffers overflow. Receive packet buffers overflow results in the dropping of received packets for a specific TC. Implement PFC by sending a timer indication to the transmitting station TC (XOFF) of a nearly full receive buffer condition at the X550. At this point the transmitter stops transmitting packets for that TC until the XOFF timer expires or a XON message is received for the stopped TC.

Similarly, once the X550 receives a priority-based XOFF it stops transmitting packets for that specific TC until the XOFF timer expires or XON packet for that TC is received.

**Figure 3-9. 802.3X Link Flow Control (PAUSE)**

Link flow control (802.3X) causes all traffic to be stopped on the link. DCB uses the same mechanism of FC but provides the ability to do PFC on TCs, as shown in [Figure 3-10](#).

**Figure 3-10. Priority Flow Control**

**Table 3-39. Packet Format for PFC**

| Field                  | Description                          |
|------------------------|--------------------------------------|
| DA                     | 01_80_C2_00_00_01 (6 bytes).         |
| SA                     | Port Ethernet MAC Address (6 bytes). |
| Type                   | 0x8808 (2 bytes).                    |
| Opcode                 | 0x0101 (2 bytes).                    |
| Priority Enable Vector | 0x00XX (2 bytes).                    |
| Timer 0                | XXXX (2 bytes).                      |
| Timer 1                | XXXX (2 bytes).                      |
| Timer 2                | XXXX (2 bytes).                      |
| Timer 3                | XXXX (2 bytes).                      |
| Timer 4                | XXXX (2 bytes).                      |
| Timer 5                | XXXX (2 bytes).                      |
| Timer 6                | XXXX (2 bytes).                      |
| Timer 7                | XXXX (2 bytes).                      |
| Pad                    | 26 bytes.                            |
| CRC                    | 4 bytes.                             |

**Table 3-40. Format of Priority Enable Vector**

|                                                            | ms octet | ls octet           |
|------------------------------------------------------------|----------|--------------------|
| Priority enable vector definition                          | 0        | e[7]...e[n]...e[0] |
| e[n] = 1 => time (n) valid<br>e[n] = 0 => time (n) invalid |          |                    |

The Priority Flow Control Type Opcode (PFCTOP) register contains the type and OpCode values for PFC. These values are compared against the respective fields in the received packet.

Each of the eight timers refers to a specific User Priority (UP), such as Timer 0 refers to UP 0, etc. The X550 binds a UP and timer to one of its TCs according to the UP-to-TC binding tables. Refer to the RTTUP2TC register for the binding of received PFC frames to Tx TCs, and to the RTRUP2TC register for the binding of transmitted PFC frames to Rx TCs.

Tx manageability traffic is bound to one the TCs via the MNGTXMAP register, and should thus be paused according to RTTUP2TC mapping when receiving PFC frames.

When a PFC frame is formatted by the X550, the same values are replicated into every *Timer* field and priority enable vector bit of all the UPs bound to the associated TC. These values are configured in the RTRUP2TC register.

The following rule is applicable for the case of multiple UPs that share the same TC (as configured in the RTTUP2TC register). When PFC frames are received with different timer values for the previously mentioned UPs, the traffic on the associated TC must be paused by the highest XOFF timer's value.

### 3.7.4.1.4 Operation and Rules

The X550 operates in either link FC or in PFC mode. Note that enabling both modes concurrently is not allowed:

- Link FC is enabled by the *RFCE* bit in the MFLCN register.
- PFC is enabled per UP by the corresponding *RPFCE* bit in the MFLCN register, and globally by MFLCN.*RPFCM* bit.

**Note:** Link FC capability must be negotiated between link partners via the auto-negotiation process. The PFC capability is negotiated via some higher level protocol and the resolution is usually provided to the driver by the DCB management agent. It is the driver's responsibility to reconfigure the link FC settings (including *RFCE* and *RPFCE*) after the auto-negotiation process was resolved.

**Note:** Receiving a link FC frame while in PFC mode might be ignored or might pause TCs in an unpredictable manner. Receiving a PFC frame while in link FC mode is ignored. Flow control events that are ignored do not increment any flow control statistics counters.

Once the receiver has validated the reception of an XOFF, or PAUSE frame, the device performs the following:

- Increment the appropriate statistics register(s)
- Initialize the pause timer based on the packet's PAUSE *Timer* field (overwriting any current timer's value)
  - For PFC, this is done per TC. If several UPs are associated with a TC, the device sets the timer to the maximum value among all enabled *Timer* fields associated with the TC.
- Disable packet transmission or schedule the disabling of transmission after the current packet completes.
  - For PFC, this is done per paused TC
  - Tx manageability traffic is bound to a specific TC as defined in the MNGTXMAP register, and is thus paused when its TC is paused

Resumption of transmission can occur under the following conditions:

- Expiration of the PAUSE timer
  - For PFC, this is done per TC
- Receiving an XON frame (a frame with its PAUSE timer set to 0b)
  - For PFC, this is done per TC

Both conditions clear the relevant TXOFF status bits in the Transmit Flow Control Status (TFCS) register and transmission can resume. Hardware records the number of received XON frames.

### 3.7.4.1.5 Timing Considerations

When operating at 10 GbE line speed, the X550 must not begin to transmit a (new) frame more than 74 pause quanta after receiving a valid Link XOFF frame, as measured at the wires (a pause quantum is 512 bit times).

When operating at 1 GbE line speed, the X550 must not begin to transmit a (new) frame more than 2 pause quanta after receiving a valid Link XOFF frame, as measured at the wires.

When operating at 100 Mb/s line speed, the X550 must not begin to transmit a (new) frame more than 1 pause quantum plus 64 bit times after receiving a valid Link XOFF frame, as measured at the wires.

The 802.1Qbb draft 2, proposes that the tolerated response time for Priority XOFF frames are the same as Link XOFF frames with extra budget of 2 pause quanta. This extra budget is aimed to compensate the fact that decision to stop new transmissions from a specific TC must be taken earlier in the transmit data path than for the Link Flow Control case.

### 3.7.4.2 PAUSE and MAC Control Frames Forwarding

Two bits in the Receive Control register control transfer of PAUSE and MAC control frames to the host. These bits are *Discard PAUSE Frames (DPF)* and *Pass MAC Control Frames (PMCF)*. Note also that any packet must pass the L2 filters as well.

- The *DPF* bit controls the transfer of PAUSE packets to the host. The same policy applies to both link FC and PFC packets as listed in [Table 3-41](#). Note that any packet must pass the L2 filters as well.
- The *Pass MAC Control Frames (PMCF)* bit controls the transfer of non-PAUSE packets to the host. Note that when link FC frames are not enabled (RFCE = 0b), link FC frames are considered as MAC control frames for this case. Similarly, when PFC frames are not enabled (RPFCM = 0b), PFC frames are considered as MAC control frames as well.

**Note:** When virtualization is enabled, forwarded control packets are queued according to the regular switching procedure defined in [Section 7.8.3.4](#).

**Table 3-41. Transfer of PAUSE Packet to Host (DPF Bit)**

| RFCE | RPFCM | DPF | Link FC Handling                                         | PFC Handling                                             |
|------|-------|-----|----------------------------------------------------------|----------------------------------------------------------|
| 0b   | 0b    | X   | Treat as MAC control (according to <i>PMCF</i> setting). | Treat as MAC control (according to <i>PMCF</i> setting). |
| 1b   | 0b    | 0b  | Accept.                                                  | Treat as MAC control (according to <i>PMCF</i> setting). |
| 1b   | 0b    | 1b  | Reject.                                                  | Treat as MAC control (according to <i>PMCF</i> setting). |
| 0b   | 1b    | 0b  | Treat as MAC control (according to <i>PMCF</i> setting). | Accept.                                                  |
| 0b   | 1b    | 1b  | Treat as MAC control (according to <i>PMCF</i> setting). | Reject.                                                  |
| 1b   | 1b    | X   | Unsupported setting.                                     | Unsupported setting.                                     |

### 3.7.4.3 Transmitting PAUSE Frames

The X550 generates PAUSE packets to ensure there is enough space in its receive packet buffers to avoid packet drop. The X550 monitors the fullness of its receive FIFOs and compares it with the contents of a programmable threshold. When the threshold is reached, the X550 sends a PAUSE frame. The X550 supports both link FC and PFC — but not both concurrently. When DCB is enabled, it only sends PFC, and when DCB is disabled, it only sends link FC.

**Note:** Similar to receiving flow control packets previously mentioned, software can enable FC transmission by setting the FCCFG.TFCE field only after it is negotiated between the link partners (possibly by auto-negotiation).

### 3.7.4.3.1 Priority Flow Control (PFC)

The X550 operates in either a link 802.3X compliant mode or in a Priority Flow Control mode, but not in both at the same time.

The same watermarks mechanism is used for PFC and for 802.3X FC to determine when to send XOFF and XON packets. When PFC is used in the receive path, priority PAUSE packets are sent instead of 802.3X PAUSE packets. The format of priority PAUSE packets is described in [Section 3.7.4.1.3](#).

Specific considerations for generating PFC packets:

- When a PFC packet is sent, the packet sets all the UPs that are associated with the relevant TC (UP-to-TC association in receive is defined in RTRUP2TC register).

### 3.7.4.3.2 Operation and Rules

The *TFCE* field in the Flow Control Configuration (FCCFG) register enables transmission of PAUSE packets as well as selects between the link FC mode and the PFC mode.

The content of the Flow Control Receive Threshold High (FCRTH) register determines at what point the X550 transmits the first PAUSE frame. The X550 monitors the fullness of the receive FIFO and compares it with the contents of FCRTH. When the threshold is reached, the X550 sends a PAUSE frame with its pause time field equal to FCTTV.

At this time, the X550 starts counting an internal shadow counter (reflecting the pause time-out counter at the partner end). When the counter reaches the value indicated in FCRTV register, then, if the PAUSE condition is still valid (meaning that the buffer fullness is still above the low watermark), an XOFF message is sent again.

Once the receive buffer fullness reaches the low water mark, the X550 sends an XON message (a PAUSE frame with a timer value of zero). Software enables this capability with the XONE field of the FCRTL.

The X550 sends a PAUSE frame if it has previously sent one and the FIFO overflows. This is intended to minimize the amount of packets dropped if the first PAUSE frame did not reach its target.

### 3.7.4.3.3 Flow Control High Threshold — FCRTH

The X550 sends a PAUSE frame when the Rx packet buffer is full above the high threshold. The threshold should be large enough to overcome the worst case latency from the time that crossing the threshold is sensed until packets are not received from the link partner.

Referring to Annex O of IEEE802.1Qbb rev 2.3, worst case latency depends on two parameters:

1. Maximum frame size over the traffic class for which FCRTH is computed. It is referred as MaxFrame(TC).
2. Maximum frame size over the link (all traffic classes altogether). It is referred as MaxFrame(link).

Three values are envisaged for MaxFrame:

- 1.5 KB (Ethernet - Jumbo disabled)
- 2.2 KB (FCoE)
- 9.5 KB (Jumbo enabled)

Worst case latency, which is referred as Standard Delay Value (Std DV), is given by:

$$\text{Std DV} = \text{MaxFrame(TC)} + \text{MaxFrame(link)} + \text{PFC Frame} + 2 \times \text{Cable Delay} + 2 \times \text{Interface Delay} + \text{Higher Layer Delay} \times \text{Sec Y Transmit Delay}$$
$$\text{Std DV (bit time units)} = \text{MaxFrame(TC)} + \text{MaxFrame(link)} + 672 + 2 \times 5,556 + 2 \times (25,600 + 8,192 + 2 \times 2,048) + 6,144 \times (\text{MaxFrame(link)} + 3,200)$$

MaxFrame(TC) term and MaxFrame(link) term included in Sec Y Transmit Delay correspond to worst case scenarios issued by the link partner. All other terms in Std DV formula must take in account worst case incoming traffic pattern which would lead to worst case buffer utilization as per the internal architecture of Rx packet buffer in the X550.

Internal architecture of the Rx packet buffer has the following restrictions:

1. Any packet starts at 32 byte aligned address.
2. Any packet has an internal status of 32 bytes. As a result, the Rx packet buffer is used at worst conditions when the Rx packet includes 65 bytes that are posted to the host memory. Assuming that the CRC bytes are not posted to host memory, in the worst case the Rx packet buffer can be filled at 1.44 higher rate than the wire speed (69-byte packet including CRC + 8-byte preamble + 12-byte back-to-back IFS consumes  $4 \times 32$  bytes = 128 bytes on the Rx packet buffer).
3. An additional packet from the concerned traffic class may be inserted into the Rx packet buffer due to the internal loopback switch \*just before\* it is decided to issue XOFF to the link partner

It leads to the below revised formula for the X550:

$$\text{X550 DV (bit time units)} = 1.44 \times [(\text{MaxFrame(link)} + 672 + 2 \times 5,556 + 2 \times (25,600 + 8,192 + 2 \times 2,048) + 6,144 \times (3,200))] + \text{MaxFrame(TC)} + \text{MaxFrame(TC)} \times \text{MaxFrame(link)}$$

FCRTH must be set to the size of the Rx packet buffer allocated to the traffic class minus the X550 DV.

**Table 3-42. X550 Delay Values (DV) Used for FCRTH**

| 9.5 KB Jumbo Enabled | FCoE Traffic Class | X550 DV |
|----------------------|--------------------|---------|
| No                   | No                 | 24 KB   |
| No                   | Yes                | 25 KB   |
| Yes                  | No                 | 50 KB   |
| Yes                  | Yes                | 35 KB   |
| No                   | No                 | 27 KB   |
| No                   | Yes                | 27 KB   |
| Yes                  | No                 | 60 KB   |
| Yes                  | Yes                | 45 KB   |

**Note:** 9.5 KB Jumbo enabled/disabled is a global setting per port which concerns all Traffic Classes except the FCoE Traffic Class.

#### 3.7.4.3.4 FC Low Threshold — FCRTL

The low threshold value is aimed to protect against wasted available host bandwidth. There is some latency from the time that the low threshold is crossed until the XON frame is sent and packets are received from the link partner. The low threshold must be set high enough so that the Rx packet buffer does not get empty before any new entire packets are received from the link partner. When considering data movement from the Rx packet buffer to host memory, large packets represent the worst. Assuming the host bandwidth is about the bandwidth on the wire (when dual ports are active at a given time), and assuming a PCIe round trip is required to get the receive descriptors, we get the following formula for FCRTL:

$$\text{FCRTL} = 2 \times \text{MaxFrame}(\text{TC}) + \text{PCIe round trip delay}$$

PCIe round trip delay is assumed to be  $\sim 1$  us and it must cover for worst case incoming traffic pattern (buffer utilization by 1.44 than wire rate):

$$\text{FCRTL (bit time units)} = 2 \times \text{MaxFrame}(\text{TC}) + 1.44 \times 10,000$$

Setting the FCRTL to lower values than expressed by the previous equation is permitted. It might simply result with potential sub-optimal use of the PCIe bus once bandwidth is available.

**Table 3-43. X550 FCRTL**

| 9.5 KB Jumbo Enabled | FCoE Traffic Class | X550 DV |
|----------------------|--------------------|---------|
| No                   | No                 | 5 KB    |
| No                   | Yes                | 7 KB    |
| Yes                  | No                 | 21 KB   |
| Yes                  | Yes                | 7 KB    |

### 3.7.4.3.5 Packet Buffer Size

When FC is enabled, the total size of a TC packet buffer must be large enough for the Low and high thresholds. To avoid constant transmission of XOFF and XON frames it is recommended to add some space for hysteresis type of behavior. The difference between the two thresholds is recommended to be at least one frame size (when 9.5 KB jumbo frames are expected over the TC) and larger than a few frames in other cases (4.5 KB for instance). If the available Rx buffer is large enough, it is recommended to increase as much as possible the hysteresis budget. If the available Rx buffer is not large enough it might be required to cut both the low threshold as well as the hysteresis budget.

- For a PFC-enabled TC:
  - $\text{FCRTH} = \text{FCRTL} + \text{hysteresis budget} = \text{FCRTL} + \text{Max}(\text{MaxFrame}(\text{TC}), 4.5 \times 1024 \text{ B})$
  - Rx Packet Buffer size =  $\text{FCRTH} + \text{the X550 DV}$  (see [Section 3.7.4.3.3](#))
- For a best effort TC:
  - Rx Packet Buffer size =  $\text{FCRTL}$ , as the same considerations than described in [Section 3.7.4.3.4](#) play here to avoid bubbles over PCIe

The total Rx Packet Buffer size available to a port for all its supported TCs is either 384 KB, 320 KB, or 256 KB, depending on the size allocated to the Flow Director table, 0 KB, 64 KB, or 128 KB, respectively.

[Table 3-44](#) assumes four PFC-enabled Traffic Classes are defined over the port, of which two are allocated to FCoE traffic and two for other loss less traffic types like iSCSI, etc. The table lists the recommended settings for the supported combinations. When less than 4 PFC-enabled TCs are defined, and/or when less than 8 TCs are defined, it is recommended to refer to the setting rules described in this section, in [Section 3.7.4.3.3](#), and in [Section 3.7.4.3.4](#). Note that reducing the number of TCs of a port to what is really needed, helps increasing the port's throughput.

Table 3-44. Some Recommended Rx Packet Buffer Settings

| Flow Director Table Size | 9.5 KB Jumbo Enabled | Packet Buffer Size of Any of the 4 Best Effort TCs | Packet Buffer Size of Any of the 2 FCoE TCs | Packet Buffer Size of Any of the Other 2 PFC-Enabled TCs |
|--------------------------|----------------------|----------------------------------------------------|---------------------------------------------|----------------------------------------------------------|
| No                       | Yes                  | 33 KB                                              | 62 KB<br>FCRTL = 7 KB<br>FCRTH = 37 KB      | 61 KB<br>FCRTL = 6 KB<br>FCRTH = 37 KB                   |
| No                       | Yes                  | 27 KB                                              | 52 KB<br>FCRTL = 7 KB<br>FCRTH = 17 KB      | 86 KB<br>FCRTL = 21 KB<br>FCRTH = 36 KB                  |

| 128 KB                   | No                   | 16 KB                                              | 48 KB<br>FCRTL = 7 KB<br>FCRTH = 21 KB      | 47 KB<br>FCRTL = 6 KB<br>FCRTH = 20 KB                   |

**Notes:**

1. In some of the cases above, it has been necessary to get compromised on the rules for hysteresis and FCRTL to fit the size available for Rx packet buffer.
2. In some other cases, after having applied all the rules there was an exceeding available Rx packet buffer left which has been used to extend the hysteresis budgets.
3. In all cases, FCRTH rule has been applied as is, since compromising on it is not allowed and extending it provides no performance benefits.

### 3.7.4.4 Link FC in DCB Mode

When operating in DCB mode, PFC is the preferred method of getting the best use of the link for all TCs. When connecting to switches that do no support (or enable) PFC, the X550 can also throttle the traffic according to incoming link FC notifications. Following is the required device setting and functionality.

- The X550 should be set to legacy link FC by setting *MFLCN.RFCE*.
- Receive XOFF pauses transmission in all TCs.
- Crossing the Rx buffer high threshold on any TC generates XOFF transmission. Each TC can have its own threshold configured by the *FCRTH[n]* registers.

- Crossing the Rx buffer Low threshold on any TC generates XON transmission. This behavior is undesired. Therefore, software should not enable XON in this mode by clearing FCRTL[n].XONE bits in all TC.
- The FCTTV of all TCs must be set to the same value.

### 3.7.5 Inter Packet Gap (IPG) Control and Pacing

The X550 supports transmission pacing by extending the IPG (the gap between consecutive packets). The pacing mode enables the average data rate to be slowed in systems that cannot support the full link rate (10 GbE, 1 GbE or 100 Mb/s). As listed in [Table 3-45](#), the pacing modes work by stretching the IPG in proportion to the data sent. In this case the data sent is measured from the end of preamble to the last byte of the packet. No allowance is made for the preamble or default IPG when using pacing mode.

#### Example 1:

Consider a 64-byte frame. To achieve a 1 GbE data rate when link rate is 10 GbE and packet length is 64 bytes (16 Dwords), add an additional IPG of 144 Dwords (nine times the packet size to reach 1 GbE). When added to the default IPG gives an IPG of 147 Dwords.

#### Example 2:

Consider a 65-byte frame. To achieve a 1 GbE data rate when link rate is 10 GbE and packet length is 65 bytes (17 Dwords when rounded up) add an additional IPG of 153 Dwords (nine times the packet duration in Dwords). When added to the default IPG gives an IPG of 156 Dwords. Note that in this case, where the packet length counted in Dwords is not an integer, count any fraction of a Dword as an entire Dword for computing the additional IPG.

[Table 3-45](#) lists the pacing configurations supported by the X550 at link rates of 10 GbE. When operating at lower link speeds the pacing speed is proportional to the link speed.

**Table 3-45. Pacing Speeds at 10 GbE Link Speed**

| Pacing Speeds (Gb/s) | Delay Inserted into IPG    | Register Value |
|----------------------|----------------------------|----------------|
| 10 (LAN)             | None                       | 0000b          |
| 9.294196 (WAN)       | 1 byte for 13 transmitted  | 1111b          |
| 9.0                  | 1 Dword for 9 transmitted  | 1001b          |
| 8.0                  | 1 Dword for 4 transmitted  | 1000b          |
| 7.0                  | 3 Dwords for 7 transmitted | 0111b          |
| 6.0                  | 2 Dwords for 3 transmitted | 0110b          |
| 5.0                  | 1 Dwords for 1 transmitted | 0101b          |
| 4.0                  | 3 Dwords for 2 transmitted | 0100b          |
| 3.0                  | 7 Dwords for 3 transmitted | 0011b          |
| 2.0                  | 4 Dwords for 1 transmitted | 0010b          |
| 1.0                  | 9 Dwords for 1 transmitted | 0001b          |
| 10                   | None                       | Default        |

Pacing is configured in the *PACE* field of the Pause and Pace (PAP) register.

## 4.0 Initialization

### 4.1 Power Up

#### 4.1.1 Power-Up Sequence

Figure 4-1 shows the X550's power-up sequence from power ramp up until it is ready to accept host commands.

Figure 4-1. X550 Power-Up Sequence

## 4.1.2 Power-Up Timing Diagram

**Figure 4-2. Power-Up Timing Diagram**

**Table 4-1. Notes for Power-Up Timing Diagram**

| No. | Note                                                                                                                                                                                                                                                       |
|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | Internal Power On Reset (POR) is released $T_{spwr}$ after power is stable and the reset pin has been de-asserted, releasing PLL kickstart.                                                                                                                |
| 2   | Bgap indication is checked. If it is good, the PLL starts calibration and lock mechanism. Once PHY PLLs are locked, the efuses are read and the clock dividers are released to provide stable clocks. Finally, the PHY releases the POR signal to the MAC. |
| 3   | MAC starts its MAC-power-up-flow and internal LAN_PWR_Good signal is asserted (clocked on 50 MHz). At this stage, internal clocks are stable.                                                                                                              |
| 4a  | Clear RAM contents                                                                                                                                                                                                                                         |
| 5   | Shadow RAM read.                                                                                                                                                                                                                                           |
| 5a  | Clear Flash write protection, Interleaved Manageability and PHY firmware load (in parallel). The FLASH accesses are active at the same time, but with only one SPI bus, the indicated times must be summed, arbitration determines which finishes first    |

**Table 4-1. Notes for Power-Up Timing Diagram (Continued)**

| No. | Note                                                                                                                                                                                                                                                                                                              |
|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6   | NVM read starts following the read of the Shadow RAM.<br>First Flash auto-read sequence is owned by the MAC to load PCI analog section, LAN and PCIe sections, APM enable, and other configuration words from legacy NVM initialization section.<br>A PERST# de-assertion restarts part of the auto-load process. |
| 5   | APM wake-up and/or manageability active, based on NVM contents (if enabled).                                                                                                                                                                                                                                      |
| 6   | In this second MAC auto-load sequence, MAC manageability and wake-up modules are loaded (if manageability / wake-up enabled).                                                                                                                                                                                     |
| 6a  | First auto-load of LAN sections: MAC module if manageability is enabled.                                                                                                                                                                                                                                          |
| 6a  | Second auto-load of LAN sections PCIe general configuration; PCIe configuration space; LAN core modules, and MAC, module if manageability is not enabled.                                                                                                                                                         |
| 7   | SVR calibration - should be done before PERST# de-assertion                                                                                                                                                                                                                                                       |
| 8   | PERST# is de-asserted by minimum $t_{PVPGL}$ after power is stable (PCIe specification).                                                                                                                                                                                                                          |
| 9   | The PCIe reference clock is valid $t_{PWRGD-CLK}$ before the de-assertion of PERST# (PCIe specification).                                                                                                                                                                                                         |
| 10  | De-assertion of PERST# to PCIe PLL stable $t_{PCIPLL}$ .                                                                                                                                                                                                                                                          |
| 12  | PCIe link training starts after $t_{pgtrn}$ from PERST# de-assertion (PCIe specification).                                                                                                                                                                                                                        |
| 13  | A first PCIe configuration access might arrive after $t_{pgcfg}$ from PERST# de-assertion (PCIe specification).                                                                                                                                                                                                   |
| 14  | A first PCI configuration response can be sent after $t_{pgres}$ from PERST# de-assertion (PCIe specification).                                                                                                                                                                                                   |
| 15  | Setting the <i>Memory Access Enable</i> or <i>Bus Master Enable</i> bits in the PCI Command register transitions the X550 from D0u to D0 state.                                                                                                                                                                   |
| 16  | BIOS software reads the PCIe driver and iSCSI/FCoE boot code from Flash, via expansion ROM.                                                                                                                                                                                                                       |
| 17  | <b>Note:</b> PHY Init Done is a per port indication.<br>This indication is used by Windows drivers (by either polling or interrupt notification) to know that PHY Device IDs are readable via MDIO. The requirement is that it is readable within a maximum of 200 ms after software reset.                       |

### 4.1.2.1 Timing Requirements

The X550 requires the following start-up and power-state transitions.

**Table 4-2. Power-Up Timing Requirements**

| Parameter       | Description                                              | Min         | Max   | Notes                            |
|-----------------|----------------------------------------------------------|-------------|-------|----------------------------------|
| $t_{xog}$       | Base 50 MHz clock stable from power stable.              |             | 10 ms |                                  |
| $t_{PWRGD-CLK}$ | PCIe clock valid to PCIe power good.                     | 100 $\mu$ s | -     | According to PCIe specification. |
| $t_{PVPGL}$     | Power rails stable to PCIe reset inactive.               | 100 ms      | -     | According to PCIe specification. |
| $t_{pgcfg}$     | External PCIe reset signal to first configuration cycle. | 100 ms      |       | According to PCIe specification. |

**Note:** It is assumed that the external 50 MHz clock source is stable after power is applied; the timing for that is part of  $t_{xog}$ .

### 4.1.2.2 Timing Guarantees

The X550 guarantees the following start-up and power-state transition related timing parameters.

**Table 4-3. Power-Up Timing Guarantees**

| Parameter      | Description                                          | Min       | Max       | Notes                                                                                                              |
|----------------|------------------------------------------------------|-----------|-----------|--------------------------------------------------------------------------------------------------------------------|
| $t_{xog}$      | Xosc stable from power stable.                       |           | 10 ms     |                                                                                                                    |
| $T_{rspor}$    | Internal POR from power stable.                      | 21,000 us | 21,000 us | Uses an internal timer based on 50MHz clock.                                                                       |
| $T_{bgg}$      | Bandgap good indication is checked.                  | 5,280 us  | 10,560 us | If the bandgap does not report good, kickstart is issued and the bandgap status is checked again after $T_{bgg}$ . |
| $T_{cal\_pll}$ | VCO calibration of one PLL                           | 41 us     | 5,200 us  | worst case timing is when this step needs to iterate.                                                              |
| $T_{pll}$      | Lock detection of one PLL is checked.                | 5,280 us  | 10,560 us | If PLL is not locked, kickstart is issued and the PLL lock status is checked again after $T_{pll}$ .               |
| $T_{clkdiv}$   | Release of reset to the clock dividers.              | 1.1 us    | 1.1 us    |                                                                                                                    |
| $T_{efuse}$    | Read EFUSE content.                                  | 500 us    | 500 us    |                                                                                                                    |
| $t_{ppg}$      | Internal MAC power good delay from valid power rail. | 37,423 us | 63,581 us | Typically the time is no worse than 42 ms.                                                                         |
| $t_{fl}$       | Flash auto-read duration.                            |           | 3 ms      |                                                                                                                    |
| $t_{opll}$     | PCIe reset to start of link training.                |           | 10 ms     |                                                                                                                    |
| $t_{pcipll}$   | PCIe reset to PCIe PLL stable.                       |           | 3 ms      |                                                                                                                    |
| $t_{pgtrn}$    | PCIe reset to start of link training.                |           | 20 ms     | According to PCIe specification.                                                                                   |
| $t_{pgres}$    | PCIe reset to first configuration response cycle.    | 100 ms    |           | According to PCIe specification.                                                                                   |
| $T_{ramc}$     | RAM clear time                                       | 81 us     |           |                                                                                                                    |
| $T_{srar}$     | Shadow RAM read time                                 | 10.8 ms   |           |                                                                                                                    |
| $T_{FWI}$      | Manageability firmware load                          | 300 ms    | 380 ms    | Assumes 12.5 MHz clock                                                                                             |
| $T_{PHYFWI}$   | PHY firmware load                                    | 160 ms    | 240 ms    | Assumes 22.5 MHz clock                                                                                             |
| $T_{CWP}$      | Clear Write protect                                  | 100 us    |           |                                                                                                                    |
| $T_{PCiana}$   | PCI Analog Section auto-load                         | 65 ms     |           |                                                                                                                    |
| $T_{SBTC}$     | PCI Analog Section auto-load                         | 7 ms      | 15 ms     |                                                                                                                    |
| $T_{BIOSL}$    | BIOS Expansion ROM auto-load                         | 700 ms    | 900 ms    | Assumes 12.5 MHz clock                                                                                             |

### 4.1.3 Main-Power/Aux-Power Operation

**Figure 4-3. Low-Power Modes Timing Diagram**

**Table 4-4. Notes for Low-Power Modes Timing Diagram**

| No. | Note                                                                                                                                                      |
|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | AUX_PWR set to 1b, indicates that the X550 should support Aux-Power Mode.                                                                                 |
| 2   | LAN_PWR_GOOD signal de-asserted.                                                                                                                          |
| 3   | Internal Power-On-Reset de-asserted, indicates to all the X550 blocks that all power-rails are OK and the external Reset signal is de-asserted (reset_n). |
| 4   | MAC_LAN_PWR_OK de-asserted (internal signal), indicates that all clocks are stable.                                                                       |
| 5   | MAC reads configuration from NVM.                                                                                                                         |
| 6   | Main-Power-OK still de-asserted, indicates that the system still runs from Aux-Power.                                                                     |
| 7   | LPLU signals asserted from MAC to PHY, indicates the PHY needs to operate at low-speed (100 Mb/s or GbE)                                                  |
| 8   | PHY reads configuration from NVM.                                                                                                                         |
| 9   | PHY Init completes.                                                                                                                                       |
| 10  | PHY auto-negotiation to 100 Mb/s or GbE and establishes link (assuming LP available).                                                                     |
| 11  | PE_RESET is still de-asserted, indicates that the system is still down, keep PCIe at reset, and the MAC at low-power modes (WoL or MNG).                  |

## 4.2 Reset Operation

### 4.2.1 Reset Sources

The X550 reset sources are described in the sections that follow. [Figure 4-4](#) and [Figure 4-5](#) describes the hierarchy between the different reset causes.

**Figure 4-4. Reset Tree (Common)**

**Figure 4-5. Reset Tree (per Port)**

#### 4.2.1.1 LAN\_PWR\_GOOD

The X550 has an internal mechanism for sensing power pins. Once power is up and stable, the X550 creates an internal reset, which acts as a master reset of the entire chip. It is level sensitive, and while it is 0b, all of the registers are held in reset. LAN\_PWR\_GOOD is interpreted to be an indication that device power supplies are all stable. Note that LAN\_PWR\_GOOD changes state during system power-up.

#### 4.2.1.2 PE\_RST\_N (PCIe Reset)

De-asserting PCIe reset indicates that both the power and the PCIe clock sources are stable. This pin also asserts an internal reset after a D3cold exit. Most units are reset on the rising edge of PCIe reset. The only exception is the GIO unit, which is kept in reset while PCIe reset is asserted (level).

### 4.2.1.3 In-Band PCIe Reset

The X550 generates an internal reset in response to a physical layer message from PCIe or when the PCIe link goes down (entry to a polling or detect state). This reset is equivalent to PCI reset in previous PCI Gigabit Ethernet (GbE) controllers.

### 4.2.1.4 D3hot to D0 Transition

This is also known as ACPI reset. The X550 generates an internal reset on the transition from D3hot power state to D0 (caused after configuration writes from a D3 to D0 power state). Note that this reset is per function and resets only the function that transitions from D3hot to D0 and do not reset the config space of the function. Its effect is equivalent to a software reset ([Section 4.2.1.6.1](#)).

### 4.2.1.5 Function Level Reset (FLR) Capability

The *FLR* bit is required for the Physical Function (PF) and per Virtual Function (VF). Setting this bit for a VF only resets the part of the logic dedicated to the specific VF and does not influence the shared part of the port. Setting the PF *FLR* bit resets the entire function.

#### 4.2.1.5.1 FLR in Non-IOV Mode

A FLR reset to a function is equivalent to a D0 → D3 → D0 transition with the exception that this reset does not require driver intervention to stop the master transactions of this function. FLR affects the device 1 parallel clock cycle from FLR assertion by default setting, or any other value defined by the *FLR Delay Disable* and *FLR Delay* fields in the *PCIe Init Configuration 2 — Offset 0x02* word in the NVM.

#### 4.2.1.5.2 Physical Function FLR (PFLR)

A FLR reset to the PF function in an IOV mode is equivalent to a FLR reset in non-IOV mode. All VFs in the PCIe function of the PF are affected.

The affected VFs are not notified of the reset in advance. The *RSTD* bit in *VFMailbox[n]* is set following the reset (per VF) to indicate to the VFs that a PF FLR took place. Each VF is responsible to probe this bit (such as after a timeout).

#### 4.2.1.5.3 Virtual Function FLR (VFLR)

A VF operating in an IOV mode can issue a FLR. VFLR resets the resources allocated to the VF (like disabling the queues and masking interrupts). It also clears the PCIe configuration for the VF. There is no impact on other VFs or on the PF.

Tx and Rx flows for the queues allocated to this VF are disabled. All pending read requests are dropped and PCIe read completions to this function can be completed as unsupported requests.

**Note:** Clearing the *IOV Enable* bit in the IOV structure is equivalent to a VFLR to all VFs in the same port.

A VFLR does not release queues that were blocked due to malicious events. The PF device driver needs to release them using the matching bit in *WQBR\_RX* and *WQBR\_TX* registers. The matching bits in these registers should be cleared after each VFLR, even if not caused due to a malicious event.

**Note:** PF driver should clear the VF's *VFMBMEM* after a VFLR is detected.

## 4.2.1.6 Soft Resets

### 4.2.1.6.1 Software Reset

Software reset is done by writing to the *Device Reset* bit of the Device Control (CTRL.RST) register. The X550 re-reads the per-function NVM fields after software reset. Bits that are not normally read from the NVM are reset to their default hardware values.

**Note:** This reset is per function and resets only the function that received the software reset.

PCI configuration space (configuration and mapping) of the device is unaffected. The MAC might or might not be reset (see [Section 4.2.3](#)).

Prior to issuing a software reset, the software driver needs to execute the master disable algorithm as defined in [Section 5.2.4.3.2](#).

If DCB is enabled, following a software reset the steps below must be executed to prevent potential races between manageability mapping to TC before and after initialization.

- Clear the Flow Control enablement in the MAC by clearing the MFLCN.RFCE (or simply clear the whole register)
- Software should wait  $\sim 10\mu\text{s}$
- The software polls the  $\text{TFCS.TC\_XON}[0] = 0$  (most of the time it is expected to be found at zero while max poll time is always shorter than the max expected PAUSE time before the software reset initiated)
- The software maps the Manageability transmit TC (setting the MNGTXMAP register) and then maps the user priority of Manageability traffic to the Manageability TC (setting the RTRUP2TC and RTTUP2TC registers)
- The software waits  $\sim 10\mu\text{s}$
- The software can re-enable the Flow Control as part of the rest of the init flow

### 4.2.1.6.2 Physical Function Software Reset

A software reset by the PF in IOV mode has the same consequences as a software reset in a non-IOV mode.

The procedure for PF software reset is as follows:

- The PF driver disables master accesses by the device through the master disable mechanism (see [Section 5.2.4.3.2](#)). Master disable affects all VFs traffic.
- Execute the procedure described in [Section 4.2.2](#) to synchronize between the PF and VFs.

VFs are expected to timeout and check on the *RSTD* bit to identify a PF software reset event. The *RSTD* bits are cleared on read.

### 4.2.1.6.3 VF Software Reset

A software reset applied by a VF is equivalent to a FLR reset to this VF with the exception that the PCIe configuration bits allocated to this function are not reset. It is activated by setting the VTCTRL.RST bit.

#### 4.2.1.6.4 Force TCO

This reset is generated when manageability logic is enabled. It is only generated if enabled by the *Force TCO Reset* bit in the *Common Firmware Parameters* word in the NVM. If enabled by the NVM, the firmware triggers a port reset by setting the CTRL.LRST bit. In pass-through mode it is generated when receiving a Force TCO SMBus or NC-SI command with bit 0 set.

#### 4.2.1.7 Link Reset

Also referred to as MAC reset.

Initiated by writing the *Link Reset* bit of the Device Control register (CTRL.LRST).

A link reset is equivalent to a software reset + reset of the MAC + reset of the PHY. The X550 re-reads the per-function NVM fields after link reset. Bits that are normally read from the NVM are reset to their default hardware values. Note that this reset is per function and resets only the function that received the link reset.

The PF in IOV mode can generate a link reset.

Prior to issuing link reset the software driver needs to execute the master disable algorithm as defined in [Section 5.2.4.3.2](#).

#### 4.2.1.8 PHY Resets

Software can reset each PHY separately via MDIO, by setting the corresponding *Soft Reset* bit in the Global Standard Control 1 register. It resets all PHY functionalities expected to PLLs; however, the PHY image is not reloaded from the NVM.

Software can at once reset a PHY (excluding PLLs) and cause a PHY image reload from the NVM, for each PHY separately, by setting via MDIO the corresponding PHY *Image Reload* bit in the Global Standard Control 1 register.

A PHY reset event causes a link down and restarts the auto-negotiation process. This can take a few seconds to complete, which might result in drop of the TCP sessions with the host and/or with a Manageability Controller (MC). Because the PHY can be accessed by the MC (via internal firmware) and by the driver software concurrently, the driver software should coordinate any PHY reset with the firmware using the following procedure:

1. Ensure that the MMNGC.MNG\_VETO bit is cleared. If it is set, the MC requires a stable link and thus the PHY should not be reset at this stage. The software driver can skip the PHY reset (if it is not mandatory) or wait for this bit to be cleared by the MC. See [Section 5.3.5.2](#) for more details on MNG\_VETO bit.
2. Take ownership of the relevant PHY using the flow described in [Section 11.8.4](#).
3. Set the *PHY Reset* bit in the Global Standard Control 1 register (or bit 0 in PHY register 1E.C442 for a PHY *Image Reload* event).
4. For a PHY reset, wait for 2  $\mu$ s before initiating any MDIO access.
5. For a PHY image re-load and before initiating any MDIO access, do one of the following:
  - a. Wait for 100 ms and poll *Global Reset Completed* bit in PHYINT\_STATUS2 register until it is set by firmware.
  - b. Wait to receive a PHY reset done interrupt.
6. Release ownership of the relevant PHY using the flow described in [Section 11.8.4](#).

## 4.2.2 Reset in PCI-IOV Environment

Several mechanisms are provided to synchronize reset procedures between the PF and the VFs.

### 4.2.2.1 RSTI/RSTD

This mechanism is provided specifically for a PF software reset but can be used in other reset cases as follows.

- One of the following reset cases takes place:
  - LAN Power Good
  - PCIe reset (PE\_RST\_N and in-band)
  - D3hot --> D0
  - FLR
  - Software reset by the PF
- The X550 sets the *RSTI* bits in all the VFMailbox registers. Once the reset completes, each VF can read its VFMailbox register to identify a reset in progress.
  - The VF can poll the *RSTI* bit to detect if the PF is in the process of configuring the device.
- Once the PF completes configuring the device, it sets the CTRL\_EXT.PFRSTD bit. As a result, the X550 clears the *RSTI* bits in all the VFMailbox registers and sets the *Reset Done (RSTD)* bits in all the VFMailbox registers.
  - The VF might read the *RSTD* bit to detect that a reset has occurred. The *RSTD* bit is cleared on read.

### 4.2.2.2 VF Receive Enable (PFVFRE)/VF Transmit Enable (PFVFTE)

This mechanism insures that a VF cannot transmit or receive before the Tx and Rx path have been initialized by the PF.

- The PFVFRE register contains a bit per VF. When the bit is set to 0b, assignment of an Rx packet for the VF's pool is disabled. When set to 1b, the assignment of an Rx packet for the VF's pool is enabled.
- The PFVFTE register contains a bit per VF. When the bit is set to 0b, fetching data for the VF's pool is disabled. When set to 1b, fetching data for the VF's pool is enabled. Fetching descriptors for the VF pool is maintained, up to the limit of the internal descriptor queues — regardless of PFVFTE settings.

PFVFTE and PFVFRE are initialized to zero (VF Tx and Rx traffic gated) following a PF reset. The relevant bits per VF are also initialized by a VF software reset or VFLR.

## 4.2.3 Reset Effects

The resets listed in [Section 4.2.1](#) affect the following registers and logic:

**Table 4-5. Reset Effects — Common Resets**

| Reset Activation                               | LAN Power Good                  | PCIe PE_RST_N     | In-Band PCIe Reset | Firmware Reset | Notes                |
|------------------------------------------------|---------------------------------|-------------------|--------------------|----------------|----------------------|
| NVM read                                       | See <a href="#">Section 6.4</a> |                   |                    |                |                      |
| LTSSM (back to detect/polling)                 | X                               | X                 | X                  |                |                      |
| PCIe link data path                            | X                               | X                 | X                  |                |                      |
| PCI configuration registers (RO)               | X                               | X                 | X                  |                | <a href="#">8</a>    |
| PCI configuration registers (RW)               | X                               | X                 | X                  |                | <a href="#">8</a>    |
| PCIe local registers                           | X                               |                   |                    |                |                      |
| Data path                                      | X                               | X                 | X                  |                | <a href="#">2, 7</a> |
| MAC, TimeSync                                  | X                               | X <sup>6</sup>    | X <sup>6</sup>     |                |                      |
| PHY (excluding PLLs)                           | X                               | X <sup>6</sup>    | X <sup>6</sup>     |                | <a href="#">15</a>   |
| PCIe analog, PHY PLLs                          | X                               |                   |                    |                |                      |
| Wake-up (PM) Context                           | X                               | <a href="#">1</a> |                    |                | <a href="#">3</a>    |
| Wake-up/manageability control/status registers | X                               |                   |                    |                | <a href="#">4, 5</a> |
| Manageability unit                             | X                               |                   |                    | X              |                      |
| LAN disable strapping pins                     | X                               | X                 | X                  |                |                      |
| All other strapping pins                       | X                               |                   |                    |                |                      |
| Shadow RAMs in MAC or PHY                      | X                               |                   |                    |                |                      |

**Table 4-6. Reset Effects — per Function Resets**

| Reset Activation                               | D3 or Dr                        | FLR or PFLR     | Software Reset  | Link Reset or Exit from LAN Disable | PHY Image Reload or PHY Reset | Notes                |
|------------------------------------------------|---------------------------------|-----------------|-----------------|-------------------------------------|-------------------------------|----------------------|
| NVM read                                       | See <a href="#">Section 6.4</a> |                 |                 |                                     |                               |                      |
| LTSSM (back to detect/polling)                 |                                 |                 |                 |                                     |                               |                      |
| PCIe link data path                            |                                 |                 |                 |                                     |                               |                      |
| PCI configuration registers (RO)               |                                 |                 |                 |                                     |                               | <a href="#">8</a>    |
| PCI configuration registers (RW)               |                                 | X               |                 |                                     |                               | <a href="#">8, 9</a> |
| Data path and memory space, TimeSync           | X                               | X               | X               | X                                   |                               | <a href="#">2, 7</a> |
| MAC                                            | X <sup>6</sup>                  | X <sup>16</sup> | X <sup>16</sup> | X                                   |                               |                      |
| PHY (excluding PLLs)                           | X <sup>6</sup>                  | X <sup>16</sup> |                 | X                                   | X                             | <a href="#">15</a>   |
| Virtual function resources                     | X                               | X               | X               |                                     |                               | <a href="#">10</a>   |
| Wake-up (PM) context                           |                                 |                 |                 |                                     |                               | <a href="#">3</a>    |
| Wake-up/manageability control/status registers |                                 |                 |                 |                                     |                               | <a href="#">4, 5</a> |
| Manageability unit                             |                                 |                 |                 |                                     |                               |                      |

**Table 4-6. Reset Effects — per Function Resets (Continued)**

| Reset Activation          | D3 or Dr | FLR or PFLR | Software Reset | Link Reset or Exit from LAN Disable | PHY Image Reload or PHY Reset | Notes |
|---------------------------|----------|-------------|----------------|-------------------------------------|-------------------------------|-------|
| Strapping pins            |          |             |                |                                     |                               |       |
| Shadow RAMs in MAC or PHY |          |             |                |                                     |                               |       |

**Table 4-7. Reset Effects — Virtual Function Resets**

| Reset Activation                     | VFLR | VF Software Reset | Notes |
|--------------------------------------|------|-------------------|-------|
| Interrupt registers                  | X    | X                 | 11    |
| Queue disable                        | X    | X                 | 12    |
| VF specific PCIe configuration space | X    |                   | 13    |
| Data path                            |      |                   |       |
| Statistics registers                 |      |                   | 14    |

**Notes for Table 4-5 through Table 4-7:**

- If AUX\_PWR = 0b the wake-up context is reset (*PME\_Status* and *PME\_En* bits should be 0b at reset if the X550 does not support PME from D3cold).
- The following register fields do not follow the general rules previously described:
  - ESDP registers — Reset on LAN Power Good only.
  - LED configuration registers — Reset on LAN Power Good and on software reset events.
  - The *Aux Power Detected* bit in the PCIe Device Status register is reset on LAN Power Good and PCIe reset only.
  - FLA — Reset on LAN Power Good only.
  - RAH/RAL[n, where n>0], MTA[n], VFTA[n], WUPM[n], FFMT[n], FFVT[n], TDBAH/TDBAL, and RDBAH/RDVAL registers have no default value. If the functions associated with these registers are enabled they must be programmed by software. Once programmed, their value is preserved through all resets as long as power is applied.
  - Statistic registers (physical function)
- The wake-up context is defined in the PCI Bus Power Management Interface specification (sticky bits). It includes:
  - PME\_En* bit of the Power Management Control/Status Register (PMCSR).
  - PME\_Status* bit of the PMCSR.
  - Aux\_En* bit in the PCIe registers.
  - The device requester ID (since it is required for PM\_PME TLP).
  - The shadow copies of these bits in the Wake-Up Control (WUC) register are treated identically.
- Refers to bits in the WUC register that are not part of the wake-up context (the *PME\_En* and *PME\_Status* bits). The WUFC register is not part of the wake-up context and is reset as part of the data path.

5. The Wake-Up Status (WUS) registers include the following:
  - WUS register.
  - Wake-Up Packet Length (WUPL) register.
  - Wake-Up Packet Memory (WUPM) register.
6. The MAC cluster and the PHY are reset by the appropriate event only if the manageability unit is disabled and the host is in a low-power state with WoL disabled. WoL disabled means either AUX\_PWR pin is cleared, or *APM Enable* bit in *NVM Control Word 3* is disabled, or ACPI is disabled (all wake-up filters are disabled or *PME\_EN* bit is disabled in PMCSR register).
7. The contents of the following memories are cleared to support the requirements of PCIe FLR:
  - The Tx packet buffers.
  - The Rx packet buffers.
8. Sticky bits and hardware init bits (indicated as HwInit) in the PCI Configuration registers are cleared only by LAN Power Good reset.
9. The following register fields are not affected by FLR or PFLR:
  - *Max\_Payload\_Size* in the Device Control register
  - Active State Power Management (ASPM) Control in the Link Control register
  - Common Clock Configuration in the Link Control register
  - Link Equalization Request in the Link Status 2 register.
  - Read Completion Boundary (RCB) in the Link Control register
  - Extended Synch in the Link Control register
  - Hardware Autonomous Speed Disable in the Link Control 2 register
  - Link Equalization Control registers in the Secondary PCI Express Extended Capability structure
10. These registers include:
  - VFEICS
  - VFEIMS
  - VFEIAC
  - VFEIAM
  - VFEITR 0-2
  - VFIVAR0
  - VFIVAR\_MISC
  - VFPBACL
  - VFMailbox
11. These registers include:
  - VFEICS
  - VFEIMS
  - VFEIMC
  - VFEIAC

- VFEIAM
  - VFEICR
  - VFEITR 0-2
  - VFIVAR0
  - VFIVAR\_MISC
  - VFPBACL
  - VFMailbox
  - RSCINT
12. These registers include specific VF bits in the FVRE and FVTE registers are cleared as well.
13. These registers include:
- MSI/MSI-X enable bits
  - BME
  - Error indications
14. Rx and Tx counters might miss proper counting due to VFLR indicating more packets than those ones actually transferred. It could happen if VFLR happened after counting occurred but before Tx or Rx completed.
15. PHY reset events that exclude PLLs reset the following blocks:
- PMA
  - PCS
  - Autoneg
  - MCP
  - PHY NVM I/F
  - Global, excluding PLLs. The PHY Image Reload command should be effective even if the PHY embedded micro controller is stuck by a faulty PHY image.
16. Concerned functionalities do not reset if the Manageability or WoL are enabled.
- Note:** Unless specified otherwise the X550's on-die memories are reset together with the functional block(s) they belong to.

## 4.3 Queue Disable

See [Section 4.6.7.1.1](#) for details on disabling and enabling an Rx queue.

See [Section 4.6.8.1.1](#) for details on disabling and enabling a Tx queue.

## 4.4 Function Disable

### 4.4.1 General

For a LAN on Motherboard (LOM) design, it might be desirable for the system to provide BIOS-setup capability for selectively enabling or disabling LAN functions. It enables end users more control over system resource-management and avoids conflicts with add-in NIC solutions. The X550 provides support for selectively enabling or disabling one or both LAN device(s) in the system.

### 4.4.2 Overview

Device presence (or non-presence) must be established early during BIOS execution, to ensure that BIOS resource-allocation (of interrupts, of memory or IO regions) is done according to devices that are present only. This is frequently accomplished using a BIOS Configuration Values Driven on Reset (CVDR) mechanism. The X550's LAN-disable mechanism is implemented to be compatible with such a solution.

The X550 provides three mechanisms to disable LAN ports and/or PCIe functions:

- The LANx\_DIS\_N pins (one pin per LAN port) are sampled on reset to determine the LAN enablement.
- One of the LAN ports can be disabled using a NVM configuration.
- Both SDP1 pins are sampled on reset to determine (electrical) disablement of both PCIe functions. If the MC is present, LAN ports are still available for manageability purposes.

Disabling a LAN port affects the PCI function it resides on. When function 0 is disabled (either LAN0 or LAN1), it does not disappear from the PCIe configuration space. Rather, the function presents itself as a dummy function. The device ID and class code of this function changes to other values (dummy function device ID 0x10A6, class code 0xFF0000). In addition, the function does not require any I/O space, and does not require an interrupt line. It requires a minimal memory space (4K) that is not mapped to internal registers.

Mapping between function and LAN ports is listed in [Table 4-8](#).

**Table 4-8. PCI Functions Mapping**

| PCI Function #                   | LAN Function Select                                           | Function 0 | Function 1 |
|----------------------------------|---------------------------------------------------------------|------------|------------|
| Both LAN functions are enabled.  | 0                                                             | LAN 0      | LAN 1      |
|                                  | 1                                                             | LAN 1      | LAN 0      |
| LAN 0 is disabled.               | 0                                                             | Dummy      | LAN1       |
|                                  | 1                                                             | LAN 1      | Disable    |
| LAN 1 is disabled.               | 0                                                             | LAN 0      | Disable    |
|                                  | 1                                                             | Dummy      | LAN 0      |
| Both LAN functions are disabled. | Both PCI functions are disabled. Device is in low-power mode. |            |            |

The following rules apply to function disable:

- When function 0 is disabled, it is converted into a dummy PCI function. Function 1 is not affected.
- When function 1 is disabled, it disappears from the PCI configuration space.

- The disabled LAN port is still available for manageability purposes if disabled through the NVM or SDP1 mechanism. In this case, and if the *LPLU* bit is set, the PHY attempts to create a link at 100 Mb/s. The disabled LAN port is not available for manageability purposes if disabled through the LANx\_DIS\_N pin mechanism. [Section 11.2.2.2](#) and [Section 11.5.3](#) describe the NC-SI channels and SMBus ports, respectively, exposed in each mode.
- Dummy function mode should not be used in PCI IOV mode (since PF0 is required to support certain functionality).

The following NVM bits control function disable:

- One PCI function can be enabled or disabled according to the *LAN\_PCI\_DISABLE* field in NVM (reflected in DEV\_FUNC\_EN.LAN\_PCI\_DISABLE bit).
- The *LAN Disable Select* field in NVM (reflected in DEV\_FUNC\_EN.LAN\_DISABLE\_SELECT bit) indicates which function is disabled.
- The *LAN\_FUNCTION\_SEL* field in NVM (reflected in FACTPS.LAN\_FUNCTION\_SEL bit) defines the correspondence between LAN port and PCI function.
- The *SDP\_FUNC\_OFF\_EN* field in NVM (reflected in DEV\_FUNC\_EN.SDP\_FUNC\_OFF\_EN bit) enables the function disable mechanism made via SDP1 pins.

When a particular LAN is fully disabled, all internal clocks to that LAN are disabled, the device is held in reset, and the internal PHY for that LAN is powered down. In both modes, the device does not respond to PCI configuration cycles. Effectively, the LAN device becomes invisible to the system from both a configuration and power consumption standpoint.

### 4.4.3 Control Options

The functions have a separate enabling mechanism. Any function that is not enabled does not function and does not expose its PCI configuration registers.

LAN0 or LAN1 can be disabled in the NVM by setting the DEV\_FUNC\_EN.LAN\_PCI\_DISABLE bit. The LAN\_DISABLE\_SELECT in the same register in the NVM selects which LAN is disabled. Furthermore, if the LAN port at function 0 is disabled, the disabled function is filled by a dummy function.

**Note:** Mapping LAN0 and LAN1 to PCI function 0 and PCI function 1 is controlled by the FACTPS.LAN\_FUNCTION\_SEL field.

LAN0 and LAN1 can be disabled on the board level by driving the LAN0\_Dis\_N or LAN1\_Dis\_N pins respectively to low. These I/O pins have weak internal pull up resistors so leaving them unconnected or driving them to high enable the respective LAN port. These pins are strapping options, sampled at LAN Power Good, PCIe reset or in-band PCIe reset.

PCIe Functions 0 and 1 can be disabled at the board level by driving SDP0\_1 or SDP1\_1 pins respectively high. These I/O pins have weak internal pull-down resistors so leaving them unconnected or driving them to low enables the PCIe functions. These pins are strapping options, sampled at PE\_RST\_N de-assertion. This feature is enabled/disabled via the DEV\_FUNC\_EN.SDP\_FUNC\_OFF\_EN bit (set from NVM Control word 2 — [Section 6.4.2.2](#)).

## 4.4.4 Event Flow for Enable/Disable Functions

This section describes the driving levels and event sequence for device functionality.

Following a power on reset / LAN Power Good/ PCIe reset/ in-band reset the LANx\_DIS\_N signals should be driven high (or left open) for normal operation. If any of the LAN functions are not required statically, its associated disable strapping pin can be tied statically to low.

Following a PCIe reset, the SDP1 pins should be driven low (or left open) for normal operation. If both PCIe functions are not required statically, the SDP1 strapping pins can be tied statically to high.

### 4.4.4.1 BIOS Disable of the LAN Function at Boot Time by Using the Strapping Option

Assume that following a power-up sequence LANx\_DIS\_N signals are driven high.

1. PCIe is established following the PCIe reset.
2. BIOS recognizes that a LAN function in the X550 should be disabled.
3. The BIOS drives the LANx\_DIS\_N signal to a low level.
4. BIOS issues a PCIe reset or an in-band PCIe reset.
5. As a result, the X550 samples the LANx\_DIS\_N signals and disables the LAN function and issues an internal reset to this function.
6. The BIOS might start with the device enumeration procedure (the disabled LAN function is invisible; changed to dummy function).
7. Proceed with normal operation.
8. Re-enable could be done by driving the LANx\_DIS\_N signal high and then requesting the end user to issue a warm boot to initialize new bus enumeration.

### 4.4.4.2 BIOS Disable of the PCIe Functions at Boot Time by Using the Strapping Option

Assume that following a power-up sequence SDP1 signals are driven low and/or the *SDP\_FUNC\_OFF\_EN* bit is cleared.

1. PCIe is established following the PCIe reset.
2. The BIOS recognizes that both PCIe functions in the X550 should be disabled.
3. The BIOS modifies the *DEV\_FUNC\_EN.SDP\_FUNC\_OFF\_EN* NVM bit and it might eventually issue an in-band PCIe reset that causes the X550 to auto-load the PCIe general configuration from the NVM.
4. The BIOS drives the two SDP1 signals to a high level.
5. The BIOS issues a PCIe reset (via PE\_RST\_N).
6. The system reboots.
7. PE\_RST\_N might toggle a couple of times during POST, before its last de-assertion.
8. As a result, the X550 samples the SDP1 signals and disables the two PCIe functions.
9. The BIOS might start with the device enumeration procedure (the disabled PCIe function is invisible and PCIe lanes are electrically off).

### 4.4.4.3 Multi-Function Advertisement

If one of the LAN devices is disabled and function 0 is the only active function, the X550 is no longer a multi-function device. The X550 normally reports 0x80 in the *PCI Configuration Header* field (*Header Type*), indicating multi-function capability. However, if a LAN is disabled and only function 0 is active, the X550 reports 0x0 in this field to signify single-function capability.

### 4.4.4.4 Interrupt Use

When both LAN devices are enabled, the X550 uses the PCI legacy interrupts of both ports for interrupt reporting. The NVM configuration controls the *Interrupt Pin* field of the PCI configuration header to be advertised for each LAN device to comply with PCI specification requirements.

However, if either LAN device is disabled, the legacy PCI interrupt of port A must be used for the remaining LAN device, therefore the NVM configuration must be set accordingly. Under these circumstances, the *Interrupt Pin* field of the PCI header always reports a value of 0x1, indicating INTA# pin usage, which means legacy PCI interrupt of port A is used.

### 4.4.4.5 Power Reporting

When both LAN devices are enabled, the PCI Power Management register block has the capability of reporting a common power value. The common power value is reflected in the *Data* field of the PCI Power Management registers. The value reported as common power is specified via an NVM field, and is reflected in the *Data* field each time the *Data\_Select* field has a value of 0x8 (0x8 = common power value select).

When only one LAN port is enabled and the X550 appears as a single-function device, the common power value, if selected, reports 0x0 (undefined value), as common power is undefined for a single-function device.

## 4.5 Device Disable

### 4.5.1 Overview

To disable the device, both LANx\_DIS\_N signals should be tied statically to low. When sampled at a power-on reset, PCIe reset, or in-band reset, the X550 is disabled. It is held in reset and power-down mode (some clocks are still running), and digital I/O pins are at High-Z if DEV\_FUNC\_EN.DEV\_OFF\_EN bit was set in *NVM Control Word 1*. As an example, digital I/O pins are in an electrical off state where pull-up/pull-down resistors are at their defined values. The manageability interface is also disabled in this state.

## 4.5.2 BIOS Disable of the Device at Boot Time by Using the Strapping Option

Assume that following a power-up sequence LANx\_DIS\_N signals are driven high.

1. PCIe is established following the PCIe reset.
2. BIOS recognizes that the X550 should be disabled.
3. The BIOS drives the LANx\_DIS\_N signals to the low level.
4. BIOS issues a PCIe reset or an in-band PCIe reset.
5. As a result, the X550 samples the LANx\_DIS\_N signals and disables the LAN ports and the PCIe connection.
6. Re-enable can be done by driving high at least one of the LANx\_DIS\_N signals and then issuing a PCIe reset to restart the device.

## 4.6 Software Initialization and Diagnostics

### 4.6.1 Introduction

This section discusses general software notes for the X550, especially initialization steps. These include:

- General hardware power-up state
- Basic device configuration
- Interrupts initialization
- Initialization of transmit
- Receive initialization
- Link configuration
- Software reset capability
- Statistics
- Diagnostic hints
- FCoE initialization
- Virtualization support initialization
- DCB configuration
- Security (IPsec) support initialization

### 4.6.2 Power-Up State

When the X550 powers up, it automatically reads the NVM. The NVM contains sufficient information to bring the link up and configure the X550 for manageability and/or APM wake-up. However, software initialization is required for normal operation.

## 4.6.3 Initialization Sequence

The following sequence of commands is typically issued to the device by the software device driver to initialize the X550 to normal operation. The major initialization steps are:

1. Disable interrupts.
2. Issue a global reset and perform general configuration — see [Section 4.6.3.2](#).
3. Wait for the NVM auto-read completion.
4. Wait for manageability configuration done indication (`EEMNGCTL.CFG_DONE0/1`).
5. Wait until the DMA initialization completes (`RDRXCTL.DMAIDONE`).
6. Setup the PHY and the link — see [Section 3.7.3.2](#) and [Section 3.7.3.3](#).
7. Initialize all statistical counters — see [Section 4.6.5](#).
8. Initialize receive — see [Section 4.6.7](#).
9. Initialize transmit — see [Section 4.6.8](#).
10. Initialize FCoE — see [Section 4.6.9](#).
11. Initialize Virtualization support — see [Section 4.6.10](#).
12. Configure DCB — see [Section 4.6.11](#).
13. Configure Security (IPsec) — see [Section 4.6.12](#).
14. Enable interrupts — see [Section 4.6.3.1](#).

### 4.6.3.1 Interrupts During Initialization

Most drivers disable interrupts during initialization to prevent re-entrance. Interrupts are disabled by writing to the EIMC register. Note that the interrupts need to also be disabled after issuing a global reset, so a typical driver initialization flow is:

1. Disable interrupts.
2. Issue a global reset.
3. Disable interrupts (again).

After initialization completes, a typical driver enables the desired interrupts by writing to the EIMS register.

### 4.6.3.2 Global Reset and General Configuration

Global reset = software reset + link reset.

Device initialization typically starts with a software reset that puts the device into a known state and enables the device driver to continue the initialization sequence. Following a global reset the software driver should poll the `CTRL.RST` until it is cleared and then wait at least 10 ms to enable a smooth initialization flow.

To enable flow control, program the `FCTTV`, `FCRTL`, `FCRTH`, `FCRTV` and `FCCFG` registers. If flow control is not enabled, these registers should be written with 0x0. If Tx flow control is enabled, Tx CRC by hardware should be enabled as well (`HLREG0.TXCRCEN` = 1b). Refer to [Section 3.7.4.3.2](#) through [Section 3.7.4.3.5](#) for recommended settings of the Rx packet buffer sizes and flow control thresholds.

**Note:** FCRTTH[n].RTH fields must be set by default regardless if flow control is enabled or not. FCRTTH[n].FCEN should be set to 0b if flow control is not enabled as all the other registers previously indicated.

The link inter-connect configuration according to the electrical specification of the relevant electrical interface should be set prior to the link setup. This configuration is done through the PHY image section of the NVM by applying the appropriate settings to the link interconnect block.

## 4.6.4 100 Mb/s, 1 GbE, and 10 GbE Link Initialization

Refer to [Section 3.7.3.3](#) and [Section 3.7.3.2](#) for the initialization and link setup steps. The device driver uses the MDIO register to initialize the PHY and setup the link. [Section 3.7.3](#) describes the usage of the MDIO register.

### 4.6.4.1 MAC Settings Automatically Based on Speed Resolved by PHY

|                   |                                                                                                                                    |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------|
| FCCFG.RFCE        | Must be set by software after reading flow control resolution from PHY registers.                                                  |
| FCCFG.TFCE        | Must be set by software after reading flow control resolution from PHY registers.                                                  |
| MAC Speed         | Speed setting is established from the PHY's internal indication to the MAC after the PHY has auto-negotiated a successful link up. |
| PHY Speed         | The speed resolution by the PHY with a link partner according to the setup made in the PHY Auto-negotiation registers.             |
| STATUS.LINKUP     | Must be set by the PF to reflect a link indication from the LINKS register. This is useful for IOV mode.                           |
| LINKS.LINK_STATUS | Reflects the PHY internal indication to the MAC.                                                                                   |
| LINKS.LINK_SPEED  | Reflects the actual speed setting negotiated by the PHY and indicated to the MAC.                                                  |

## 4.6.5 Initialization of Statistics

Statistics registers are hardware-initialized to values as detailed in each particular register's description. The initialization of these registers begins upon transition to a D0 active power state (when internal registers become accessible, as enabled by setting the *Memory Access Enable* field of the PCIe Command register), and is guaranteed to complete within 1 ms of this transition. Note that access to statistics registers prior to this interval might return indeterminate values.

All statistical counters are cleared on read and a typical device driver reads them (thus making them zero) as a part of the initialization sequence.

Queue counters are mapped using the RQSMR registers for Rx queues, and TQSM registers for Tx queues. Refer to the RQSMR register section for RQSMR setup, and to the TQSM register section for TQSM setup. Note that if software requires the queue counters, the RQSMR and TQSM registers must be reprogrammed following a device reset.

## 4.6.6 Interrupt Initialization

### 4.6.6.1 Working with Legacy or MSI Interrupts

- Software driver associates between Tx and Rx interrupt causes and the EICR register by setting the IVAR[n] registers
- Program the SRRCTL[n].RDMTS per receive queue if software uses the Receive Descriptor Minimum Threshold Interrupt (RDMTI).
- All interrupts should be set to zero — no auto clear in the EIAC register. Following an interrupt software can read the EICR register to check for the interrupt causes.
- Set the auto mask in the EIAM register according to the preferred mode of operation.
- Set the interrupt throttling in the EITR[n] and GPIE according to the preferred mode of operation.
- The software enable the required interrupt causes by setting the EIMS register.

### 4.6.6.2 Operating with MSI-X

- The operating system/BIOS sets hardware to MSI-X mode and programs the MSI-X table as part of the device enumeration procedure.
- The software driver associates between interrupt causes and MSI-X vectors and the throttling timers EITR[n] by programming the IVAR[n] and IVAR\_MISC registers.
- Program the SRRCTL[n].RDMTS (per receive queue) if software uses the receive descriptor minimum threshold interrupt.
- The EIAC[n] registers should be set to auto clear for transmit and receive interrupt causes (for best performance). The EIAC bits that control the other and TCP timer interrupt causes should be set to 0b — no auto clear.
- Set auto mask in the EIAM, EIAM[n] registers according to the preferred mode of operation.
- Set the interrupt throttling in the EITR[n] and GPIE registers according to the preferred mode of operation.
- Software clears EICR by writing all ones to clear old interrupt causes.
- Software enables the required interrupt causes by setting the EIMS[n] registers.

## 4.6.7 Receive Initialization

Initialize the following register tables before receive and transmit is enabled:

- Set CTRL\_EXT.Extended\_VLAN bit if needed
- Receive Address (RAL[n] and RAH[n]) for used addresses and Receive Address High — RAH[n].VAL=0b for unused addresses
- Unicast Table Array — PFUTA[n]
- VLAN Filter Table Array — VFTA[n]
- VLAN Pool Filter — PFVLVF[n]
- MAC Pool Select Array — MPSAR[n]

- VLAN Pool Filter Bitmap — PFVLVFB[n].

Program the Receive Address register(s) (RAL[n], RAH[n]) per the station address. This can come from the NVM or from any other means (for example, it could be stored anywhere in the NVM or even in the platform PROM for a LOM design).

Set up the Multicast Table Array — MTA registers. Assuming the entire table was zeroed by the last reset, only the desired multicast addresses should be permitted (by writing 0x1 to the corresponding bit location). Set the MCSTCTRL.MFE bit if multicast filtering is required.

Set up the VLAN Filter Table Array — VFTA if VLAN support is required. Assuming the entire table was zeroed by the last reset, only the desired VLAN addresses should be permitted (by writing 0x1 to the corresponding bit location). Set the VLNCTRL.VFE bit if VLAN filtering is required.

Initialize the flexible filters 0...7 — Flexible Host Filter Table (FHFT\_FILTER) registers.

After all memories in the filter units previously indicated are initialized, enable ECC reporting by setting the RXFECCERR0.ECCFLT\_EN bit.

Program the different Rx filters and Rx offloads via registers FCTRL, VLNCTRL, MCSTCTRL, RXCSUM, RQTC, RFCTL, MPSAR, RSSRK, RETA, SDPQF, FTQF, SYNQF, ETQF, ETQS, RDRXCTL, RSCDBU.

**Note:** As NFS detection is not supported, the RFCTL.NFSW\_DIS and RFCTL.NFSR\_DIS bits should be set to 1b.

Program RXPBSIZE, MRQC, PFQDE, RTRUP2TC, MFLCN.RPFCE, MFLCN.RPFCM, and MFLCN.RFCE according to the DCB and virtualization modes. Refer to [Section 4.6.11.3](#).

Enable receive jumbo frames by setting HLREG0.JUMBOEN in the following case:

1. Jumbo packets are expected. Set MAXFRS.MFS to the expected maximum packet size.

Enable receive coalescing if required as described in [Section 4.6.7.2](#).

### 4.6.7.1 Receive Queues Enable

The following should be done for each receive queue:

1. Allocate a region of memory for the receive descriptor list.
2. Receive buffers of appropriate size should be allocated and pointers to these buffers should be stored in the descriptor ring.
3. Program the descriptor base address with the address of the region (registers RDBAH, RDBAL).
4. Set the length register to the size of the descriptor ring (register RDLEN).
5. Program SRRCTL associated with this queue according to the size of the buffers and the required header control.
6. Set RXDCTL[n].RLPML field enabled by the RXDCTL[n].RLPML\_EN limiting the maximum Rx packet size. This setting is optional enabling the software to use smaller buffers than the size defined by the SRRCTL[n].BSIZEPACKET. Software may not use smaller buffers than defined by the SRRCTL[n] on Rx queues that enables RSC.
7. If header split is required for this queue, program the appropriate PSRTYPE for the appropriate headers.
8. Program RSC mode for the queue via RSCCTL register.
9. Program RXDCTL with appropriate values including the queue *Enable* bit. Note that packets directed to a disabled queue are dropped.

10. Poll the RXDCTL register until the *Enable* bit is set. The tail should not be bumped before this bit was read as 1b.
11. Bump the tail pointer (*RDT*) to enable descriptors fetching by setting it to the ring length minus one.

Enable the receive path by setting *RXCTRL.RXEN*. This should be done only after all other settings are done. If software uses the receive descriptor minimum threshold interrupt, that value should be set.

#### 4.6.7.1.1 Dynamic Enabling and Disabling of Receive Queues

Receive queues can be enabled or disabled dynamically using the following procedure.

##### Enabling:

Follow the per-queue initialization described in the previous section.

##### Disabling:

1. Disable the routing of packets to this queue by re-configuring the Rx filters.
2. If RSC is enabled on the specific queue and VLAN strip is enabled as well, wait two ITR expiration times (ensure all open RSCs completed).
3. All FCoE DDP flows related to this queue must be invalidated by the software device driver prior to disabling the queue.
4. Disable the queue by clearing the *RXDCTL.ENABLE* bit. The X550 stops fetching and writing back descriptors from this queue. Any further packet that is directed to this queue is dropped. If a packet is being processed, the X550 completes the current buffer write. If the packet spreads over more than one data buffer, all subsequent buffers are not written.
5. The X550 clears the *RXDCTL.ENABLE* bit only after all pending memory accesses to the descriptor ring are done. The driver should poll this bit before releasing the memory allocated to this queue.
6. Once the *RXDCTL.ENABLE* bit is cleared the driver should wait an additional amount of time (~100 µs) before releasing the memory allocated to this queue.

The Rx path can be disabled only after all the receive queues are disabled.

**Note:** As there could be additional packets in the receive packet buffer targeted to the disabled queue and the arbitration could be such that it would take a long time to drain these packets, if software re-enables a queue before all packets to that queue were drained, the enabled queue could potentially get packets directed to the old configuration of the queue. For example, VM goes down and a different VM gets the queue. The software device driver should delay the re-enablement of the queue until it is guaranteed there are no more packets directed to this queue in the packet buffer.

#### 4.6.7.2 RSC Enablement

RSC enablement as well as RSC parameter settings are assumed as static. It should be enabled prior receiving and can be disabled only after the relevant Rx queue(s) are disabled.

##### 4.6.7.2.1 RSC Global Setting

- Enable global CRC stripping via the *HLREG0* register (hardware default setting).
- Software device driver should set the *RDRXCTL.RSCACKC* bit that forces RSC completion on any change of the *ACK* bit in the Rx packet relative to the RSC context.

- The `SRRCTL[n].BSIZEHEADER` (header buffer size) bit must be larger than the packet header (even if header split is not enabled). A minimum size of 128 bytes for the header buffer addresses this requirement.

#### 4.6.7.2.2 RSC per Queue Setting

- Enable RSC and configure the maximum allowed descriptors per RSC by setting the `MAXDESC` and `RSCEN` fields in the `RSCCTL[n]` register.
- Use a non-legacy descriptor type by setting the `SRRCTL[n].DESCTYPE` bit to non-zero values.
- TCP header recognition: the `PSR_TYPE4` bit in the `PSRTYPE[n]` registers should be set.
- The `SRRCTL[n].BSIZEPACKET` (packet buffer size) must be 2 KB at minimum.
- Interrupt setting:
  - Interrupt moderation must be enabled by setting the `EITR[n].ITR_INTERVAL` bit to a value greater than zero. The `ITR_INTERVAL` bit must be larger than the `RSC Delay` field described later. Note that if the `CNT_WDIS` bit is cleared (write enable), the `ITR_COUNTER` bit should be set to 0b.
  - The `RSC_DELAY` field in the `GPIE` register should be set to the expected system latency descriptor write-back cycles. 4 to 8  $\mu$ s should be sufficient in most cases. If software sees cases where RSC did not complete as expected (following EITR interrupt assertion), the `RSC_DELAY` field might need to be increased.
  - Map the relevant Rx queues to an interrupt by setting the relevant `IVAR` registers.

#### 4.6.7.3 Flow Director Initialization

Flow Director initialization is described in [Section 7.1.3.6.11](#).

### 4.6.8 Transmit Initialization

- Program the `HLREG0` register according to the MAC behavior needed.
- Program the TCP segmentation parameters via registers `DMATXCTL` (while keeping the `TE` bit cleared), `DTXTCPFLGL`, `DTXTCPFLGH`, and `TPH` parameters via `TPH_TXCTRL`.
- Refer to the IPG description in [Section 3.7.5](#) for more details.
- Set `RTTDCS.ARBDIS` to 1.
- Program the `DTXMXSZRQ`, `TXPBSIZE`, `TXPBTHRESH`, `MTQC`, and `MNGTXMAP` registers according to the DCB and virtualization modes. Refer to [Section 4.6.11.3](#).
- Clear `RTTDCS.ARBDIS` to 0.
- Legacy drivers that uses queue zero and assumes it is enabled by default, should at this stage, set queue zero parameters as described below.
- Enable the transmit path by setting the `DMATXCTL.TE` bit.

### 4.6.8.1 Transmit Queues Enable

The following steps should be done once for each transmit queue:

1. Allocate a region of memory for the transmit descriptor list.
2. Program the descriptor base address with the address of the region (TDBAL and TDBAH).
3. Set the length register to the size of the descriptor ring (TDLEN).
4. If needed, set TDWBAL/TWDBAH to enable head write back.
5. Program the TXDCTL register with the desired Tx descriptor write-back policy (see the recommended values in the register description).
6. Enable the queue using the TXDCTL.ENABLE bit. Poll the TXDCTL register until the *ENABLE* bit is set.

**Note:** Queue 0 is enabled by default when the DMATXCTL.TE bit is set. If transmit is already enabled (DMATXCTL.TE bit is set), this queue should be disabled (clear TXDCTL.ENABLE bit) before changing the basic queue parameters (TDBAL, TDBAH, TDLEN, TDWBAL/TWDBAH).

**Note:** The tail register of the queue (TDT) should not be bumped until the queue is enabled.

#### 4.6.8.1.1 Dynamic Enabling and Disabling of Transmit Queues

Transmit queues can be enabled or disabled dynamically given the following procedure is followed.

##### Enabling:

Follow the per-queue initialization described in the previous section.

##### Disabling:

1. Stop storing packets for transmission in this queue.
2. The completion of the last transmit descriptor must be visible to software to guarantee that packets are not lost in step 5 ([Section 4.6.8](#)). Therefore, its *RS* bit must be set or *WTHRESH* must be greater than zero. If none of the previous conditions are met, software should add a null Tx data descriptor with an active *RS* bit.
3. Wait until the software head of the queue (*TDH*) equals the software tail (*TDT*) indicating the queue is empty.
4. Wait until all descriptors are written back (polling the *DD* bit in ring or polling the *Head\_WB* content). It might be required to flush the transmit queue by setting the TXDCTL[n].SWFLSH bit if the *RS* bit in the last fetched descriptor is not set or if *WTHRESH* is greater than zero.
5. Disable the queue by clearing TXDCTL.ENABLE.
6. Any packets waiting for transmission in the packet buffer would still be sent at a later time.

The transmit path can be disabled only after all transmit queues are disabled.

## 4.6.9 FCoE Initialization Flow

Ordering between the following steps is not critical as long as it is done before transmit and receive starts.

- The FCoE DDP context table should be initialized clearing the `FCBUFF.VALID` bit and the `FCFLT.VALID` bit of all contexts.
- EType Queue Filter — `ETQF[n]`: Select a filter by setting the `FCOE` bit. The `ETYPE` field should be set to 0x8906 (FCoE Ethernet Type).
- EType Queue Select — `ETQS[n]`: Each `ETQF` filter is associated to a queue select register. The `ETQS` registers can be used to direct the FCoE traffic to specific receive queues. Up to one queue per Traffic Class (TC) as programmed in the `ETQF`.
- Multiple receive queues can be enabled by setting the `FCRECTL.ENA` bit and programming the `FCRETA[n]` registers.
- Set the `RDRXCTL.FCOE_WRFIX` bit that forces a DDP write exchange context closure after receiving the last packet in a sequence with an active *Sequence Initiative* bit in the `F_CTL` field.
- Follow the rules described in [Section 7.11.2.1](#) and [Section 7.11.3.1](#) for Tx and Rx cross-functionality requirements. These sections include requirements on Ethernet CRC and padding handling, legacy Rx buffers, etc.

## 4.6.10 Virtualization Initialization Flow

### 4.6.10.1 VMDq Mode

#### 4.6.10.1.1 Global Filtering and Offload Capabilities

- Select one of the VMDQ pooling and queuing methods
  - Pool Selection can be based on MAC/VLAN, and optionally E-tag. The filtering mode is defined using the `PFVTCTL.POOLING_MODE` field.
- Queue in poll can be based either on DCB or RSS. Potential values for `MRQC.MRQE` to set VMDq modes are 1000b to 1111b.
- DCB should be initiated as described in [Section 4.6.11](#). In RSS mode, the RSS key (`VFRSSRK`) and redirection table (`VFRETA`) of the pool should be programmed. The usage of DCB can be controlled per pool.
- Configure the `PFVTCTL` register to define the default pool.
- Enable replication via the `PFVTCTL.RPL_EN` bit.
- If needed, enable padding of small packets via the `HLREG0.TXPADEN` bit.
- The MPSAR registers are used to associate Ethernet MAC Addresses to pools. Using the MPSAR registers, software must reprogram `RAL[0]` and `RAH[0]` by their values (software could read these registers and then write them back with the same content).

#### 4.6.10.1.2 Mirroring Rules

For each mirroring rule to be activated:

- Set the type of traffic to be mirrored in the PFMRECTL[n] register. Only one type of traffic can be selected in each rule.
- Set the mirror pool by setting the PFMRECTL[n].MP bit.
- For pool mirroring, set the PFMVRM[n] register with the pools to be mirrored.
- For VLAN mirroring, set the PFMVRLAN[n] register with the indexes from the PFVLVF registers of the VLANs to be mirrored.

#### 4.6.10.1.3 Security Features

For each pool, the driver might activate the MAC, VLAN and Ethertype anti-spoof features via the relevant bit in the PFVFSPOOF.MACAS, PFVFSPOOF.VLANAS, PFVFSPOOF.ETHERTYPEAS, and PFVFSPOOF.ETHERTYPELB fields, respectively.

In addition, stripping and hiding of VLAN and external tag (E-tag) may also be requested via the PFQDE.HIDE\_VLAN and PFQDE.STRIP\_TAG flags, respectively.

#### 4.6.10.1.4 Per-Pool Settings

As soon as a pool of queues is associated to a VM, software should set the following parameters:

- Associate the unicast Ethernet MAC Address of the VM by enabling the pool in the MPSAR registers.
- If all the Ethernet MAC Addresses are used, the Unicast Hash Table (PFUTA) can be used. Pools servicing VMs whose address is in the hash table should be declared as so by setting the PFVML2FLT.ROPE bit. Packets received according to this method didn't pass perfect filtering and are indicated as such.
- Enable the pool in all RAH/RAL registers representing the multicast Ethernet MAC Addresses this VM belongs to.
- If all the Ethernet MAC Addresses are used, the Multicast Hash Table (MTA) can be used. Pools servicing VMs using multicast addresses in the hash table should be declared as so by setting the PFVML2FLT.ROMPE bit. Packets received according to this method did not pass perfect filtering and are indicated as such.
- Define whether this VM should get all multicast/broadcast packets in the same VLAN via PFVML2FLT.MPE and PFVML2FLT.BAM, and whether it should accept un-tagged packets via PFVML2FLT.AUPE.
- Enable the pool in each of the PFVLVF and PFVLVFB registers this VM belongs to.
- A VM might be set to receive it's own traffic in case the source and the destination are in the same pool via the PFVMTXSW.LLE bit.
- Whether VLAN header and CRC should be stripped from the packet. Note that even if the CRC is kept, it might not match the actual content of the forwarded packet, because of other offloading applications such as VLAN strip.
  - A striped VLAN may be also hidden from the VM.
- Set which header split is required via the PSRTYPE register.

- In RSS mode, define if the pool uses RSS via the proper MRQC.MRQE mode.
  - Enable the Pool in the PFVFRE register to allow Rx Filtering
  - To Enable Multiple Tx queues, Set the MTQC as described in [Section 7.2.1.2.1](#)
  - Enable the Pool in the PFVFTE register to allow Tx Filtering
- Enable Rx and Tx queues as described in [Section 4.6.7](#) and [Section 4.6.8](#).
- For each Rx queue a drop/no drop flag can be set in SRRCTL.DROP\_EN and via the PFQDE register, controlling the behavior in cases no receive buffers are available in the queue to receive packets. The usual behavior is to allow a drop to avoid head of line blocking. Setting the PFQDE (per queue) is done by using the QUEUE\_INDEX field in the PFQDE register.

## 4.6.10.2 IOV Initialization

### 4.6.10.2.1 PF Driver Initialization

The PF driver is responsible for the link setup and handling of all the filtering and offload capabilities for all the VFs as described in [Section 4.6.10.1.1](#) and the security features as described in [Section 4.6.10.1.3](#). It should also set the bandwidth allocation per transmit queue for each VF as described in [Section 4.6.10](#).

**Note:** Link setup might include the authentication process (802.1X or other) and setup of the DCB parameters.

After all the common parameters are set, the PF driver should set all the VFMailbox[n].RSTD bits by setting the CTRL\_EXT.PFRSTD bit.

PF enables VF traffic via the PFVFTE and PFVFRE registers after all VF parameters are set as defined in [Section 4.6.10.1.4](#).

**Note:** If the operating system changes the NumVF setting in the PCIe SR-IOV Num VFs register after the device was active, it is required to initiate a PF software reset following this change.

#### 4.6.10.2.1.1 VF Specific Reset Coordination

After the PF driver receives an indication of a VF FLR via the PFVFLREC register, it should enable the receive and transmit for the VF only once the device is programmed with the right parameters as defined in [Section 4.6.10.1.4](#). The receive filtering is enabled using the PFVFRE register and the transmit filtering is enabled via the PFVFTE register.

**Note:** The filtering and offloads setup might be based on a central IT settings or on requests from the VF drivers.

#### 4.6.10.2.2 VF Driver Initialization

At initialization, after the PF indicated that the global initialization was done via the VFMailbox.RSTD bit, the VF driver should communicate with the PF, either via the mailbox or via other software mechanisms to assure that the right parameters of the VF are programmed as described in [Section 4.6.10.1.4](#). The PF driver might then send an acknowledge message with the actual setup done according to the VF request and the IT policy.

The VF driver should then setup the interrupts and the queues as described in [Section 4.6.6](#), [Section 4.6.7](#), and [Section 4.6.8](#).

#### 4.6.10.2.3 Full Reset Coordination

A mechanism is provided to synchronize reset procedures between the PF and the VFs. It is provided specifically for PF software reset but can be used in other reset cases as described later in this section.

The procedure is as follows:

One of the following reset cases takes place:

- LAN Power Good
- PCIe reset (PE\_RST\_N and in-band)
- D3hot --> D0
- FLR
- Software reset by the PF

The X550 sets the *RSTI* bits in all VFMailbox registers. Once the reset completes, each VF might read its VFMailbox register to identify a reset in progress.

Once the PF completes configuring the device, it clears the CTRL\_EXT.PFRSTD bit. As a result, the X550 clears the *RSTI* bits in all VFMailbox registers and sets the *Reset Done (RSTD)* bits are set in all VFMailbox registers.

Until a RSTD condition is detected, the VFs should only access the VFMailbox register and should not attempt to activate the interrupt mechanism or the transmit and receive process.

### 4.6.11 DCB Configuration

After power-up or device reset, DCB and any type of FC are disabled by default, and a unique TC and packet buffer (such as PB0) is used. In this mode, the host might exchange information via DCX protocol to determine the number of TCs to be configured. Before setting the device to multiple TCs, it should be reset (software reset).

The registers concerned with setting the number of TCs are: RXPBSIZE[0-7], TXPBSIZE[0-7], TXPBTHRESH, MRQC, MTQC, and RTRUP2TC registers as well as the following bits RTRPCS.RAC, RTTDCS.TDPAC, RTTDCS.VMPAC and RTTPCS.TPPAC.

They cannot be modified on the fly, but only after device reset. Packet buffers with a non-null size must be allocated from PB0 and up.

Rate parameters and bandwidth allocation to VMs can be modified on the fly without disturbing traffic flows.

#### 4.6.11.1 CPU Latency Considerations

When the CPU detects an idle period of some length, it enters a low-power sleep state. When traffic arrives from the network, it takes time for the CPU to wake and respond (such as to snoop). During that period, Rx packets are not posted to system memory.

If the entry time-to-sleep state is too short, the CPU might be getting in and out of its sleep state in between packets, therefore impacting latency and throughput. 100  $\mu$ s is defined as a safe margin for entry time to avoid such effects.

Each time the CPU is in low power, received packets need to be stored (or dropped) in the X550 for the duration of the exit time. Given 64 KB Rx packet buffers per TC in the X550, (i.e. assuming typically 4 TCs per port) PFC does not spread (or the packet is not dropped) provided the CPU exits its low power state within 50  $\mu$ s.

#### 4.6.11.2 Link Speed Change Procedure

Each time the link status or speed is changed, hardware automatically updates the rates that were loaded by software relatively to the new link speed. This means that if a rate limiter was set by software to 500 Mb/s for a 10 GbE link speed, it is changed by hardware to 50 Mb/s if the link speed has changed to 1 GbE.

Since rates must be considered as absolute rate limitations (expressed in Mb/s, regardless of the link speed), in such cases software is responsible to either clear all the rate-limiters and/or re-load each rate with the correct value relatively to the new link speed. In the previous example, the new rate value to be loaded by software must be multiplied by 10 to maintain the rate limitation to 500 Mb/s.

#### 4.6.11.3 Initial Configuration Flow

Only the following configuration modes are allowed.

##### 4.6.11.3.1 General Case: DCB-On, VT-On

1. Configure packet buffers, queues, and traffic mapping:

- 8 TCs mode — Packet buffer size and threshold, typically  $RXPBSIZE[0-7].SIZE = 0x30, 0x28, \text{ or } 0x20$ , depending on the size of the flow director table. Refer to rules in [Section 3.7.4.3.5](#) for a non-symmetrical sizing.

$TXPBSIZE[0-7].SIZE = 0x14$

but non-symmetrical sizing is also allowed (see rules in the TXPBSIZE register)

$TXPBTHRESH.THRESH[0-7] = TXPBSIZE[0-7].SIZE$  — Max expected Tx packet length in this TC.

- 4 TCs mode — Packet buffer size and threshold, typically  $RXPBSIZE[0-3].SIZE = 0x60, 0x50, \text{ or } 0x40$ , depending on the size of the flow director table. Refer to rules in [Section 3.7.4.3.5](#) for a non-symmetrical sizing.

$RXPBSIZE[[4-7].SIZE = 0x0$

$TXPBSIZE[0-3].SIZE = 0x28$

$TXPBSIZE[4-7].SIZE = 0x0$

but non-symmetrical sizing among TCs[0-3] is also allowed (see rules in TXPBSIZE register)

$TXPBTHRESH.THRESH[0-3] = TXPBSIZE[0-3].SIZE$  — Maximum expected Tx packet length in this TC.

$TXPBTHRESH.THRESH[4-7] = 0x0$

- Multiple Receive and Transmit Queue Control (MRQC and MTQC)
    - Set MRQC.MRQE to 1xxxb, with the 3 LS bits set according to the number of VFs, TCs, and RSS mode as listed in the MRQC register section.
    - Set both DCB\_ENA and VT\_ENA bits in the MTQC register.
    - Set MTQC.NUM\_TC\_OR\_Q according to the number of TCs/VFs enabled as described in the MTQC register section.
  - Set the PFVTCTL.VT\_ENA bit (as the MRQC.VT\_ENA bit) Queue Drop Enable (PFQDE): In SR-IOV the PFQDE bit should be set to 1b in the PFQDE register for all queues. In VMDq mode, the PFQDE bit should be set to 0b for all queues.
  - Split Receive Control (SRRCTL[0-127]): DROP\_EN = 1b — drop policy for all the queues, to avoid crosstalk between VMs
  - Rx User Priority (UP)-to-TC (RTRUP2TC)
  - Tx UP-to-TC (RTTUP2TC)
  - DMA Tx TCP Max Allow Size Requests (DTXMXSZRQ) — set MAX\_BYTE\_NUM\_REQ = 0x010 = 4 KB.
  - Operate the SEC-TX buffer in DCB mode by setting SECTXMINIFG.MRKRINSERT to 0x640 or to 0x1A0 depending if 9.5 KB Jumbo frames are supported or not, respectively.
2. Enable PFC and disable legacy flow control:
- Enables transmit priority flow control via: FCCFG.TFCE = 10b, and for the TC(s) where no drop behavior is required by FCRTTH.FCEN = 1b and appropriate setting in corresponding FCRTL.RTL and FCRTTH.RTH.
- Note:** FCRTL.RTL must be set to a non zero value when FCRTTH.FCEN = 1b.
- Enables receive priority flow control via MFLCN.RPFCM = 1b and MFLCN.RPFCE set for the UP(s) where no drop behavior is required.
  - Disable receive legacy flow control via MFLCN.RFCE = 0b.
  - Refer to [Section 8.2.2.3](#) for other registers concerned with flow control
3. Configure arbiters, per TC[0-1]:
- Tx Descriptor Plane T1 Config (RTTDT1C) per queue, via setting RTTDQSEL first
  - Tx Descriptor Plane T2 Config (RTTDT2C[0-7])
  - Tx Packet Plane T2 Config (RTTPT2C[0-7])
  - Rx Packet Plane T4 Config (RTRPT4C[0-7])
4. Enable TC and VM arbitration layers:
- Tx Descriptor Plane Control and Status (RTTDCS), bits: TDPAC = 1b, VMPAC = 1, TDRM = 1b, BDPM = 0b, BPBFSM = 0b.
  - Tx Packet Plane Control and Status (RTTPCS): TPPAC = 1b, TPRM = 1b, ARBD = 0x004, BYPASS\_DCB\_ARB = 0
  - Rx Packet Plane Control and Status (RTRPCS): RAC = 1b, RRM = 1b

#### 4.6.11.3.2 DCB-On, VT-Off

Set the configuration bits as specified in [Section 4.6.11.3.1](#) with the following exceptions:

- Configure packet buffers, queues, and traffic mapping:
  - MRQC and MTQC
    - Set *MRQE* to 0xxxb, with the 3 LS bits set according to the number of TCs, and RSS mode
    - Set the *DCB\_ENA* bit and clear the *VT\_ENA* bit in the MTQC register.
    - Set *MTQC.NUM\_TC\_OR\_Q* according to the number of TCs enabled
  - Clear the *PFVTCTL.VT\_ENA* bit (as the *MRQC.VT\_ENA* bit)
- Allow no-drop policy in Rx:
  - *PFQDE*: The *PFQDE* bit should be set to 0b in the *PFQDE* register for all queues enabling per queue policy by the *SRRCTL[n]* setting.
  - Split Receive Control (*SRRCTL[0-127]*): The *DROP\_EN* bit should be set (per receive queue) according to the required drop / no-drop policy of the TC of the queue.
- Disable VM arbitration layer:
  - Clear the *RTTDT1C* register, per each queue, via setting *RTTDQSEL* first
  - *RTTDCS.VMPAC* = 0b

#### 4.6.11.3.3 DCB-Off, VT-On

Set the configuration bits as specified in [Section 4.6.11.3.1](#) with the following exceptions:

- Disable multiple packet buffers and allocate all queues to PB0:
  - *RXPBSIZE[0].SIZE* = 0x180, *RXPBSIZE[1-7].SIZE* = 0x0
  - *TXPBSIZE[0].SIZE* = 0xA0, *TXPBSIZE[1-7].SIZE* = 0x0
  - *TXPBTHRESH.THRESH[0]* = 0xA0 — Max expected Tx packet length in this TC  
*TXPBTHRESH.THRESH[1-7]* = 0x0
  - MRQC and MTQC
    - Set *MRQE* to 1xxxb, with the 3 LS bits set according to the number of VFs and RSS mode
    - Clear *DCB\_ENA* bit and set the *VT\_ENA* bit in the MTQC register.
    - Set *MTQC.NUM\_TC\_OR\_Q* according to the number of VFs enabled
  - Set the *PFVTCTL.VT\_ENA* bit (as the *MRQC.VT\_ENA* bit) Rx UP-to-TC (*RTRUP2TC*), *UPnMAP*=0, *n*=0,...,7
  - Tx UP-to-TC (*RTTUP2TC*), *UPnMAP*=0, *n*=0,...,7
  - DMA Tx TCP Max Allow Size Requests (*DTXMXSZRQ*) — set *MAX\_BYTE\_NUM\_REQ* = 0xFFFF = 1 MB
  - Operate the SEC-TX buffer in non-DCB mode by setting *SECTXMINIFG.MRKRINSERT* to 0x10
- Disable PFC and enabled legacy flow control:
  - Disable receive priority flow control via: *MFLCN.RPFCM* = 0b and *MFLCN.RPFCE[7:0]* = 0x00
  - Enable transmit legacy flow control via: *FCCFG.TFCE* = 01b

- Enable receive legacy flow control via:  $MFLCN.RFCE = 1b$
- Configure VM arbiters only, reset others:
  - Tx Descriptor Plane T1 Config (RTTDT1C) per pool, via setting RTTDQSEL first for the pool index. Clear RTTDT1C for other queues.
  - Clear RTTDT2C[0-7] registers
  - Clear RTTPT2C[0-7] registers
  - Clear RTRPT4C[0-7] registers
- Disable TC arbitrations while enabling the PB Free Space Monitor:
  - Tx Descriptor Plane Control and Status (RTTDCS), bits:  $TDPAC = 0b$ ,  $VMPAC = 1b$ ,  $TDRM = 0b$ ,  $BDPM = 1b$ ,  $BPBFSM = 0b$
  - Tx Packet Plane Control and Status (RTTPCS):  $TPPAC = 0b$ ,  $TPRM = 0b$ ,  $ARBD = 0x24$ ,  $BYPASS\_DCB\_ARB = 1$ .
  - Rx Packet Plane Control and Status (RTRPCS):  $RAC = 0b$ ,  $RRM = 0b$

#### 4.6.11.3.4 DCB-Off, VT-Off

Set the configuration bits as specified in [Section 4.6.11.3.1](#) with the following exceptions:

- Disable multiple packet buffers and allocate all queues and traffic to PB0:
  - $RXPBSIZE[0].SIZE = 0x180$ ,  $RXPBSIZE[1-7].SIZE = 0x0$
  - $TXPBSIZE[0].SIZE = 0xA0$ ,  $TXPBSIZE[1-7].SIZE = 0x0$
  - $TXPBTHRESH.THRESH[0] = 0xA0$  — Max expected Tx packet length in this TC  
 $TXPBTHRESH.THRESH[1-7] = 0x0$
  - MRQC and MTQC
    - Set  $MRQE$  to 0xxx, with the 3 LS bits set according to the RSS mode
    - Clear both  $DCB\_ENA$  and  $VT\_ENA$  bits in the MTQC register.
    - Set  $MTQC.NUM\_TC\_OR\_Q$  to 00b.
  - Clear the  $PFVTCTL.VT\_ENA$  bit (as the  $MRQC.VT\_ENA$  bit) Rx UP-to-TC (RTRUP2TC),  
 $UPnMAP=0$ ,  $n=0,...,7$
  - Tx UP-to-TC (RTTUP2TC),  $UPnMAP=0$ ,  $n=0,...,7$
  - DMA Tx TCP Max Allow Size Requests (DTXMXSZRQ) — set  $MAX\_BYTE\_NUM\_REQ = 0xFFF = 1\text{ MB}$
  - Operate the SEC-TX buffer in non-DCB mode by setting  $SECTXMINIFG.MRKRINSERT$  to 0x10
- Allow no-drop policy in Rx:
  - PFQDE: The  $PFQDE$  bit should be set to 0b in the PFQDE register for all queues enabling per queue policy by the  $SRRCTL[n]$  setting.
  - Split Receive Control ( $SRRCTL[0-127]$ ): The  $DROP\_EN$  bit should be set (per receive queue) according to the required drop / no-drop policy of the TC of the queue.

- Disable PFC and enable legacy flow control:
  - Disable receive priority flow control via: `MFLCN.RPFCM` = 0b and `MFLCN.RPFCE[7:0]` = 0x00
  - Enable receive legacy flow control via: `MFLCN.RFCE` = 1b
  - Enable transmit legacy flow control via: `FCCFG.TFCE` = 01b
- Reset all arbiters:
  - Clear the RTTDT1C register, per each queue, via setting RTTDQSEL first
  - Clear RTTDT2C[0-7] registers
  - Clear RTTPT2C[0-7] registers
  - Clear RTRPT4C[0-7] registers
- Disable TC and VM arbitration layers:
  - Tx Descriptor Plane Control and Status (RTTDCS), bits: `TDPAC` = 0b, `VMPAC` = 0b, `TDRM` = 0b, `BDPM` = 1b, `BPBFSM` = 1b
  - Tx Packet Plane Control and Status (RTTPCS): `TPPAC` = 0b, `TPRM` = 0b, `ARBD` = 0x224
  - Rx Packet Plane Control and Status (RTRPCS): `RAC` = 0b, `RRM` = 0b

## 4.6.11.4 Configuration Rules

### 4.6.11.4.1 TC Parameters

#### Traffic Class (TC)

Per 802.1p priority #7 is the highest priority.

A specific TC can be configured to receive or transmit a specific amount of the total bandwidth available per port.

Bandwidth allocation is defined as a fraction of the total available bandwidth, which can be less than the full Ethernet link bandwidth (if it is bounded by the PCIe bandwidth or by flow control).

Low latency TC should be configured to use the highest priority TC possible (TC 6, 7); the lowest latency is achieved using TC7.

#### Bandwidth Groups (BWGs)

BWGs are used to represent different traffic types. A traffic type (such as storage, IPC LAN, or manageability) can have more than one TC. For example, one for control traffic and one for the raw data. By grouping these two TCs to a BWG, the end user can allocate bandwidth to the storage traffic so that unused bandwidth by the control could be used by the data and vice versa. This BWG concept supports the converged fabric as each traffic type, that's used to run on a different fabric, can be configured as a BWG and gets its resources as if it was on a different fabric.

1. To configure DCB not to share bandwidth between TCs, each TC should be configured as a separate BWG.
2. There are no limits on the TCs that can be bundled together as a BWG. All TCs can be configured as a single BWG.
3. BWG numbers should be sequential starting from zero until the total number of BWG minus one.
4. BWG numbers do not imply priority; priority is only set according to TCs.

## Refill Credits

Refill credits regulate the bandwidth allocated to BWGs and TCs. The ratio between the credits of the BWG's represents the relative bandwidth percentage allocated to each BWG. The ratio between the credits of the TC's represents the relative bandwidth percentage allocated to each TC within a BWG.

Credits are configured and calculated using 64-byte granularity.

1. In any case, the number of refill credits assigned per TC should be as small as possible but still larger than the maximum frame size used and larger than 1.5 KB. Using a lower refill value causes more refill cycles before a packet can be sent. These extra cycles unnecessarily increase the latency.
2. Refill credits ratio between TCs should be equal to the desired ratio of bandwidth allocation between the different TCs. Applying rule #1, means bandwidth shares are sorted from the smaller to the bigger, and just one maximum sized frame is allocated to the smallest.
3. The ratio between the refill credits of any two TCs should not be greater than 100.
4. Exception to rule #2 — TCs that require low latency should be configured so that they are under subscribed. For example, the credit refill value should provide these TCs somewhat more bandwidth than what they actually need. Low latency TCs should always have credits so they can be next in line for WSP arbitration.

This exception causes the low latency TC to always have maximum credits (as it starts with maximum credits and on average cycle uses less than the refill credits).

The end point that is sending/receiving packets of 127 bytes eventually get double the bandwidth it was configured to, as all credits calculated by rounding the values down to the next 64 byte-aligned value.

## Max Credit Limit

The maximum credit limit value establishes a limit for the number of credits that a TC or BWG can own at any given time. This value prevents stacking up stale credits that can be added up over a relatively long period of time and then used by TCs all at once, altering fairness and latency.

Max credit limits are configured and calculated using 64-byte granularity.

1. Maximum credit limit should be bigger than the refill credits allocated to the TC.
2. Maximum limit should be set to be as low as possible while still meeting other rules to minimize the latency impact on low latency TCs.
3. If a low latency TC generates a burst that is larger than its maximum credit limit, this TC might experience higher latency since the TC needs to wait for allocation of additional credits because it finished all its credits for this cycle. Therefore, maximum credit limit for a low latency TC must be set bigger than the maximum burst length of traffic expected on that TC — for all VMs at once. If TC7 and TC6 are for low latency traffic, it leads to:

$$\text{Max}(\text{TC7},6) \geq \text{MaxBurst}(\text{TC7},6) \text{ served with low latency}$$

4. An arbitration cycle can be extended when one or more TCs accumulate credits more than their refill values (up to their maximum credit limit). For such a case a low latency TC should be provided with enough credits to cover for the extended cycle duration. Since the low latency TC operates at maximum credits (see rule #3) its maximum credit limit should meet the following formula.

$$\{\text{Max}(\text{TCx})/\text{SUM}_{i=0..7}[\text{Max}(\text{TCi})]\} \geq \{\text{BW}(\text{TCx})/\text{Full BW}\}$$

The formula applies to both the descriptor arbiter and data arbiter.

5. To ensure bandwidth for a low priority TC (when those are allocated with most of the bandwidth) the maximum credit value of the low priority TC in the data arbiter needs to be high enough to ensure sync between the two arbiters. In the following equation the bandwidth numbers are from the descriptor arbiter while the maximum values are of the data arbiter.

$$\{\text{Max}(\text{TCx})/\text{SUMi}=\text{x}+1..7[\text{Max}(\text{TCi})]\} \geq \{\text{BW}(\text{TCx})/\text{Full\_PCIE\_BW}\}$$

Note that the previous equation is worst case and covers the assumption that all higher TCs have the full maximum to transmit.

**Tip:** A simplified maximum credits allocation scheme would be to find the minimum number  $N \geq 2$  such that rules #3 and #5 are respected, and allocate:

$$\text{Max}(\text{TCi}) = N \times \text{Refill}(\text{TCi}), \text{ for } i=0\dots7$$

By maintaining the same ratios between the maximum credits and the bandwidth shares, the bandwidth allocation scheme is made more immune to disturbing events such as receiving priority pause frames with short timer values.

### GSP and LSP

**Bit TC.LSP (TC Link Strict Priority):** This bit specifies that the configured TC can transmit without any restriction of credits. This effectively means that the TC can take up the entire link bandwidth, unless preempted by higher priority traffic. The Tx queues associated with a LSP TC must be set as strict low latency in the TXLLQ[n] registers.

**Bit TC.GSP (TC Strict Priority within Group):** This bit defines whether strict priority is enabled or disabled for this TC within its BWG. If bit TC.GSP is set to 1b, the TC is scheduled for transmission using strict priority. It does not check for availability of credits in the TC. It does; however, check whether the BWG of this TC has credits. For example, the amount of traffic generated from this TC is still limited by the bandwidth allocated for the BWG.

1. TC's with the *LSP* bit set should be the first to be considered by the scheduler. This implies that the *LSP* bit should be configured to the highest priority TC's. For example, starting from priority 7 and down; the other TC's should be used for groups with bandwidth allocation. It is recommended to use *LSP* only for one TC (TC7) as the first LSP TC takes its bandwidth and there are no guarantees to the lower priority LSPs.
2. The *GSP* bit can be set to more than one TC in a BWG, always from the highest priority TC within that BWG downward. For the LAN scenario, all TCs could be configured to be GSP as their bandwidth needs are not known.
3. For a low latency TC where the *GSP* bit is set, non-null refill credits must be set for at least one maximum-sized frame. This ensures that even after its been quiet for a while, some BWG credits are left available to the GSP TC, for serving it with minimum latency (without waiting for replenishing). Bigger refill credits values ensure longer bursts of GSP traffic served with minimum latency.

## 4.6.11.4.2 VM Parameters

### Refill Credits

Refill credits regulate the fraction of the TC's bandwidth that is allocated to a VM. The ratio between the credits of the VMs represent the relative TC bandwidth percentage allocated to each VM.

Credits are configured and calculated using 64-byte granularity.

1. In any case, the number of refill credits assigned per VM should be as small as possible but still larger than the maximum frame size used and larger than 1.5 KB. Using a lower refill value causes more refill cycles before a packet can be sent. These extra cycles increase the latency unnecessarily.

2. The refill credits ratio between VMs should be equal to the desired ratio of bandwidth allocation between the different TCs. Applying rule #1, means bandwidth shares are sorted from the smaller to the bigger, and just one maximum sized frame is allocated to the smallest.
3. The ratio between the refill credits of any two VMs within the TC should not be greater than 10.

VMs that send/receive packets of 127 bytes eventually get double the bandwidth it was configured to as all credits are calculated by rounding the values down to the next 64 byte-aligned value.

#### Refill and Maximum Credits (MaxCredits) Setting Example:

This example assumes a system with only four TCs and three VMs present, along with the following bandwidth allocation scheme. Also, note that full PCIe bandwidth is evaluated to 15 G.

**Table 4-9. Bandwidth Share Example**

| TCs and VMs |       | Bandwidth Share% | Note                                                                                         |
|-------------|-------|------------------|----------------------------------------------------------------------------------------------|
| TC0         | Total | 40               | 9.5 KB jumbo frames allowed.                                                                 |
|             | VM0   | 60               |                                                                                              |
|             | VM1   | 30               |                                                                                              |
|             | VM2   | 10               |                                                                                              |
| TC1         | Total | 20               | No jumbo frames.                                                                             |
|             | VM0   | 34               |                                                                                              |
|             | VM1   | 33               |                                                                                              |
|             | VM2   | 33               |                                                                                              |
| TC2         | Total | 30               | Low latency TC. No jumbo frames.<br>Bandwidth share already increased.<br>MaxBurstTC2=120 KB |
|             | VM0   | 80               |                                                                                              |
|             | VM1   | 10               |                                                                                              |
|             | VM2   | 10               |                                                                                              |
| TC3         | Total | 10               | Low latency LSP TC.<br>No jumbo frames.<br>MaxBurstTC3=36 KB                                 |
|             | VM0   | 20               |                                                                                              |
|             | VM1   | 60               |                                                                                              |
|             | VM2   | 20               |                                                                                              |

The ratios between TC refills are driven by TC0, which was set as 152 for supporting 9.5 KB jumbo frames.

The ratio between MaxCredits and Refill were taken as 17 for all the TCs, as driven by the TC2 relation between MaxCredits and MaxBurstTC2.

**Table 4-10. Refill and MaxCredits Settings**

| TCs and VMs |       | Refill<br>(64-Byte Units) | MaxCredits<br>(64-Byte Units) |
|-------------|-------|---------------------------|-------------------------------|
| TC0         | Total | 152                       | 2584                          |
|             | VM0   | 912                       |                               |
|             | VM1   | 456                       |                               |
|             | VM2   | 152                       |                               |
| TC1         | Total | 76                        | 1292                          |
|             | VM0   | 25                        |                               |
|             | VM1   | 24                        |                               |
|             | VM2   | 24                        |                               |
| TC2         | Total | 114                       | 1938                          |
|             | VM0   | 192                       |                               |
|             | VM1   | 24                        |                               |
|             | VM2   | 24                        |                               |
| TC3         | Total | 38                        | 646                           |
|             | VM0   | 24                        |                               |
|             | VM1   | 72                        |                               |
|             | VM2   | 24                        |                               |

#### 4.6.11.4.3 Rate Limiters

It might be useful to setup rate limiters on Tx queues (rate-limiting VF traffic). Setting a rate-limiter on Tx queue N to a Target Rate requires the following settings:

- Use of advanced Tx descriptors
- `RTTQCNRM.MMW_SIZE` set to the amount of back-to-back compensation to be granted to a quiet item.
- `RTTDQSEL.TXQ_IDX` set to N.
- Compute the Rate Factor = Link Speed / Target Rate, where Link Speed is either 10 Gb/s or 1 Gb/s. The fractional binary number obtained is broken down into its  $2^n$  components as follows:
 
$$b_9b_8b_7b_6b_5b_4b_3b_2b_1b_0.b_{-1}b_{-2}b_{-3}b_{-4}b_{-5}b_{-6}b_{-7}b_{-8}b_{-9}b_{-10}b_{-11}b_{-12}b_{-13}b_{-14}$$
 where  $b_n$  is the binary coefficient of the  $2^n$  component
- Set `RTTQCNRC` register with
  - Set `RTTQCNRC[13:0] = RTTQCNRC.RF_DEC[13:0] = [b_{-1}b_{-2}b_{-3}b_{-4}b_{-5}b_{-6}b_{-7}b_{-8}b_{-9}b_{-10}b_{-11}b_{-12}b_{-13}b_{-14}]`
  - `RTTQCNRC[23:14] = RTTQCNRC.RF_INT[9:0] = [b_9b_8b_7b_6b_5b_4b_3b_2b_1b_0]`
  - `RTTQCNRC[31] = RTTQCNRC.RS_ENA = 1b`

### Numerical Example:

- Target Rate = 4 Gb/s
  - Link Speed = 10 Gb/s
- Rate Factor =  $10 / 4 = 2.5 = 1 \times 2^1 + 1 \times 2^{-1} = 0000000010.10000000000000b$
- RTTQCNRC[13:0] = [10000000000000]
  - RTTQCNRC[23:14] = [0000000010]
  - RTTQCNRC = [1000 0000 0000 0000 1010 0000 0000 0000] = 0x8000A000

## 4.6.12 Security Initialization

After power up or device reset, security offload is disabled by default (IPsec), and the content of the SA tables must be cleared by software.

Security offload cannot be enabled when either the security fuses are blown (set to zero), or the ENCRYPTION\_EN pin is set to 0b. In this case, IPsec is disabled and the following security-related fields are not writable:

- SEXTXCTRL.SECTX\_DIS is set to 1b and read as 1b
- SECRXCTRL.SECRX\_DIS is set to b1 and read as 1b
- IPSTXIDX.IPS\_TX\_EN is cleared to 0b and read as 0b
- IPSRXIDX.IPS\_RX\_EN is cleared to 0b and read as 0b

Security offload can be used when the security offload internal fuse is enabled and the ENCRYPTION\_EN pin set to 1b. In this case, the security offload can be enabled/disabled via the flows that are described in the sections that follow.

### 4.6.12.1 Security Enable Flow

To enable one of the security modes do the following:

1. Stop the data paths by setting the SEXTXCTRL.TX\_DIS and SECRXCTRL.RX\_DIS bits.
2. Wait for the data paths to be emptied by hardware. Poll the SEXTXSTAT.SECTX\_RDY and SECRXSTAT.SECRX\_RDY bits until they are both asserted by hardware.
3. Clear the SEXTXCTRL.SECTX\_DIS and SECRXCTRL.SECRX\_DIS bits to enable the Tx and Rx crypto engines.
  - When enabling IPsec offload, set the SEXTXMINIFG.MINSECIFG bits to 0x3, extending back-to-back gap to the security block required for its functionality.
  - When enabling IPsec, set the SEXTXCTRL.STORE\_FORWARD bit, since a store and forward IPsec buffer is required for the processing of AH packets (ICV field insertion is done at the beginning of the frame). Otherwise, clear this bit.
  - When enabling IPsec, write the SEC buffer almost full threshold register SEXTXBUFAF.FULLTHRESH with the value of 0x15.
4. Enable SA lookup:
  - For IPsec, set the IPSTXIDX.IPS\_TX\_EN and the IPSRXIDX.IPS\_RX\_EN bits.
5. Restart the data paths by clearing the SEXTXCTRL.TX\_DIS and SECRXCTRL.RX\_DIS bits.

### 4.6.12.2 Security Disable Flow

To disable one of the security modes do the following:

1. Stop the data paths by setting the `SECTXCTRL.TX_DIS` and `SECRXCTRL.RX_DIS` bits.
2. Wait for the data paths to be emptied by hardware. Poll the `SECTXSTAT.SECTX_RDY` and `SECRXSTAT.SECRX_RDY` bits until they are both asserted by hardware.
3. Disable SA lookup:
  - For IPsec, clear the `IPSTXIDX.IPS_TX_EN` and the `IPSRXIDX.IPS_RX_EN` bits.
4. Set the `SECTXCTRL.SECTX_DIS` and `SECRXCTRL.SECRX_DIS` bits to disable the Tx and Rx crypto engines.
  - When disabling IPsec, clear the `SECTXCTRL.STORE_FORWARD` bit to avoid using the IPsec buffer and thus reducing Tx internal latency.
  - When disabling IPsec, write the SEC buffer almost full threshold register `SECTXBUFFAF.FULLTHRESH` with the value of 0x250.
5. Restart the data paths by clearing the `SECTXCTRL.TX_DIS` and `SECRXCTRL.RX_DIS` bits.

**Note:** Disabling the crypto engine reduces the X550's power consumption.

### 4.6.13 Alternate MAC Address Support

In some systems, the MAC Address used by a port needs to be replaced with a temporary MAC Address in a way that is transparent to the software layer. One possible usage is in blade systems, to allow a standby blade to use the MAC Address of another blade that failed, so that the network image of the entire blade system does not change.

To allow this mode, a management console might change the MAC Address in the NVM image. It is important in this case to be able to keep the original MAC Address of the device as programmed at the factory.

To support this mode, the X550 provides the Alternate Ethernet MAC Address structure in the NVM to store the original MAC Addresses. This structure is described in [Section 6.3.7](#).

In some systems, it might be advantageous to restore the original MAC Address at power on reset, to avoid conflicts where two network controllers would have the same MAC Address.

The X550 supports replacement of the MAC Address with an alternate MAC Address via the NC-SI interface using the BIOS CLP interface as described in the BIOS CLP document.

#### 4.6.13.1 LAN MAC Address Restore

The X550 restores the LAN MAC Addresses stored in the Alternate Ethernet MAC Address structure to the regular LAN MAC Address location (see [Section 6.4.7.2](#)) if the following conditions are met:

1. The *restore MAC Address* bit in the *Common Firmware Parameters* NVM word is set.
2. The value in word 0x37 is not 0xFFFF.
3. The MAC Address set in the regular MAC Address location is different than the address stored in the Alternate Ethernet MAC Address structure.

4. The addresses stored in the Alternate Ethernet MAC Address structure are valid (not all zeros or all ones).

If the value at word 0x37 is valid, but the MAC Addresses in the Alternate MAC structure are not valid (0xFFFFFFFF or all zeros) and *restore MAC Address* NVM bit is set, the regular MAC Address is backed up in the Alternate MAC structure.

### 4.6.13.2 SAN MAC Address Restore

The X550 restores the SAN MAC Addresses (word 0x28 - see [Section 6.3.4.5](#)) at power on reset by copying the values from the Alternate SAN MAC Address structure (word 0x27; [Section 6.3.4.4](#)) to the SAN MAC Addresses if the following conditions are met:

1. The *Restore MAC Address* bit in the *Common Firmware Parameters* NVM word is set.
2. The pointer to the SAN MAC Address structure is valid (value in word 0x28 is not 0xFFFF - see [Section 6.3.4.5](#)).
3. The addresses stored in the Alternate SAN MAC Address structure (word 0x27 - see [Section 6.3.4.4.1](#)) are valid (not all zeros or all ones).

If the value at word 0x27 is valid, but the MAC Addresses in the Alternate SAN MAC structure are not valid (0xFFFFFFFF or all zeros), the regular SAN MAC Address (pointed by word 0x28) is backed up in the Alternate SAN MAC structure (pointed by word 0x27).

### 4.6.13.3 Restore Reporting

If after the power up cycle, the alternate SAN and LAN address equals to the SAN and LAN Factory MAC Addresses (either they were restored by the internal firmware or they were originally equal), the *FWSM.FACTORY\_MAC\_ADDRESS\_RESTORED* bit is set. This bit is common to all ports.

## 4.7 Access to Shared Resources

Part of the resources in the X550 are shared between several software entities — namely the drivers of the two ports and internal firmware. To avoid contentions, a driver that needs to access one of these resources should use the *Gaining Control of Shared Resource by Software* flow described in [Section 11.8.4.1](#) to acquire ownership of this resource, and use the *Releasing a Shared Resource by Software* flow described in [Section 11.8.4.2](#) to relinquish ownership of this resource.

The shared resources are:

- NVM
- PHY 0 and PHY 1 registers
- MAC CSRs

**NOTE:**      *This page intentionally left blank.*

## 5.0 Power Management and Delivery

This section defines how power management is implemented in the X550.

### 5.1 Power Targets and Power Delivery

See [Section 12.3.9](#) for the current consumption and [Section 12.3.2](#) for the power supply specification.

### 5.2 Power Management

#### 5.2.1 Introduction to X550 Power States

The X550 supports the D0 and D3 power states defined in the PCI Power Management and PCIe specifications. D0 is divided into two sub-states: D0u (D0 un-initialized), and D0a (D0 active). In addition, the X550 supports a Dr state that is entered when PE\_RST\_N pin is asserted (including the D3cold state).

[Figure 5-1](#) shows the power states and transitions between them.

**Figure 5-1. Power Management State Diagram**

## 5.2.2 Auxiliary Power Usage

The X550 uses the *AUX\_PWR* indication that auxiliary power is available to the controller, and therefore advertises D3cold wake-up support in the *PMC.PME\_Support* field and sets the *Aux\_Power\_Detected* bit in the PCIe capability structure *Device Status* Register. The *AUX\_PWR* pin is strapped during Power On Reset (POR). The amount of power required for the function, which includes the entire Network Interface Card (NIC), is advertised in the Power Management Data register, which is loaded from the NVM.

The only effect of setting *AUX\_PWR* to 1b is advertising D3cold wake-up support and changing the reset function of *PME\_En* and *PME\_Status*. *AUX\_PWR* is a strapping option in the X550. If D3cold is supported, the *PME\_En* and *PME\_Status* bits of the Power Management Control/Status Register (PMCSR), as well as their shadow bits in the Wake-Up Control Register (WUC) are reset only by the power up reset (detection of power rising). The X550 tracks the *PME\_En* bit of the PMCSR and the Auxiliary (AUX) power *PM Enable* bit of the PCIe Device Control register to determine the power it can consume (and therefore its power state) in the D3cold state (internal Dr state). Note that the actual amount of power differs between form factors.

According to the following settings the X550 might consume higher auxiliary power than is allowed by PCIe specifications:

- If the *AUX Power PM Enable* bit of the PCIe Device Control register is set, the X550 might consume higher power for any purpose (even if *PME\_En* is not set).
- If the *AUX Power PM Enable* bit of the PCIe Device Control register is cleared, higher power consumption is determined by the PCI-PM legacy *PME\_En* bit of the PMCSR.

## 5.2.3 PCIe Link Power Management

The PCIe link state follows the power management state of the device. Since the X550 incorporates multiple PCI functions, the device power management state is defined as the power management state of the most awake function:

- If any function is in D0a state in ARI mode or either D0a or D0u in non-ARI mode, the PCIe link assumes the device is in D0 state.
- Else, if in ARI mode, at least one of the functions is in D3 state and the other functions are not in D0a state, or if in non-ARI mode all of the functions are in the D3 state, the PCIe link assumes the device is in D3 state.
- Else, the device is in Dr state (*PE\_RST\_N* is asserted to all functions).

The X550 supports the following PCIe power management link states:

- L0 state is used in D0u and D0a states.
- The L1 state is used in D0a and D0u states each time link conditions apply, as well as in the D3 state.
- The L2 state is used in the Dr state following a transition from a D3 state if PCI-PM PME is enabled.
- The L3 state is used in the Dr state following power up, on transition from D0a and also if PME is not enabled in other Dr transitions.

The X550 support for active state link power management is reported via the PCIe Active State Link PM Support register loaded from NVM.

The following NVM fields control L1 behavior:

- Act\_Stat\_PM\_Sup — Indicates support for ASPM L1 in the PCIe configuration space (loaded into the *Active State Link PM Support* field).
- L1\_Act\_Ext\_Latency — Defines L1 active exit latency.
- L1\_Act\_Acc\_Latency — Defines L1 active acceptable exit latency.

## 5.2.4 Power States

### 5.2.4.1 D0uninitialized State

The D0u state is a low-power state used after PE\_RST\_N is de-asserted following power-up (cold or warm), on hot reset (in-band reset through PCIe physical layer message) or on D3 exit.

When entering D0u, the X550 disables wake-ups.

#### 5.2.4.1.1 Entry to a D0u State

D0u is reached from either the Dr state (on de-assertion of Internal PE\_RST\_N) or the D3hot state (by configuration software writing a value of 00b to the *Power State* field of the PCI PM registers).

De-asserting internal PE\_RST\_N means that the entire state of the device is cleared, other than sticky bits. State is loaded from the NVM, followed by establishment of the PCIe link. Once this is done, configuration software can access the device.

On a transition from D3 to D0u state, the X550 requires that software perform a full re-initialization of the function not including its PCI configuration space which is kept while in D3.

### 5.2.4.2 D0active State

Once memory space is enabled, the X550 enters an active state. It can transmit and receive packets if properly configured by the software device driver. The PHY is enabled or re-enabled by the software device driver to operate/auto-negotiate to full line speed/power if not already operating at full capability. Any APM wake-up previously active remains active. The software device driver can deactivate ACPI wake-up by writing to the Wake-Up Control (WUC) register and APM wake-up by writing to the General Receive Control (GRC) register, or activate other wake-up filters by writing to the Wake-Up Filter Control (WUFC) register.

#### 5.2.4.2.1 Entry to D0a State

D0a is entered from the D0u state by writing a 1b to the *Memory Access Enable* or the *I/O Access Enable* bit of the PCI Command register. The DMA, MAC, and PHY of the appropriate LAN function are enabled.

### 5.2.4.3 D3 State (PCI-PM D3hot)

The X550 transitions to D3 when the system writes a 11b to the *Power State* field of the PMCSR. Any wake-up filter settings that were enabled before entering this reset state are maintained. Upon transition to D3 state, the X550 clears the *Memory Access Enable* and *I/O Access Enable* bits of the PCI Command register, which disables memory access decode. In D3 the X550 only responds to PCI configuration accesses and does not generate master cycles.

Configuration and message requests are the only PCIe TLPs accepted by a function in the D3hot state. All other received requests must be handled as unsupported requests, and all received completions can optionally be handled as unexpected completions. If an error caused by a received TLP (like an unsupported request) is detected while in D3hot, and reporting is enabled, the link must be returned to L0 if it is not already in L0 and an error message must be sent. See section 5.3.1.4.1 in the PCIe Base Specification.

A D3 state is followed by either a D0u state (in preparation for a D0a state) or by a transition to Dr state (PCI-PM D3cold state). To transition back to D0u, the system writes a 00b to the *Power State* field of the PMCSR. Transition to Dr state is through PE\_RST\_N assertion.

#### 5.2.4.3.1 Entry to D3 State

Transition to D3 state is through a configuration write to the *Power State* field of the PCI-PM registers.

Prior to transition from D0 to the D3 state, the software device driver disables scheduling of further tasks to the X550; it masks all interrupts, it does not write to the Transmit Descriptor Tail (TDT) register or to the Receive Descriptor Tail (RDT) register and operates the master disable algorithm as defined in [Section 5.2.4.3.2](#). If wake-up capability is needed, the software device driver should set up the appropriate wake-up registers and the system should write a 1b to the *PME\_En* bit of the PMCSR prior to the transition to D3.

If all PCI functions are programmed into D3 state, the X550 brings its PCIe link into the L1 link state. As part of the transition into L1 state, the X550 suspends scheduling of new TLPs and waits for the completion of all previous TLPs it has sent. The X550 clears the *Memory Access Enable* and *I/O Access Enable* bits of the PCI Command register, which disables memory access decode. Any receive packets that have not been transferred into system memory is kept in the device (and discarded later on D3 exit). Any transmit packets that have not been sent can still be transmitted (assuming the Ethernet link is up).

In preparation to a possible transition to D3cold state, and to reduce power consumption, whenever entering D3 state, the software device driver might disable one of the LAN ports (LAN disable) and/or the PHY(s) auto-negotiate network link(s) to a lower speed (if supported by the network interface). See [Section 5.3.5.2](#) for a description of network interface behavior in this case.

### 5.2.4.3.2 Master Disable

System software might disable master accesses on the PCIe link by either clearing the *PCI Bus Master* bit or by bringing the function into a D3 state. From that time on, the X550 must not issue master accesses for this function. Due to the full-duplex nature of PCIe, and the pipelined design in the X550, it might happen that multiple requests from several functions are pending when the master disable request arrives. The protocol described in this section insures that a function does not issue master requests to the PCIe link after its *Master Enable* bit is cleared (or after entry to D3 state).

Two configuration bits are provided for the handshake between the device function and its software device driver:

- *PCIe Master Disable* bit in the Device Control Register (CTRL) register — When the *PCIe Master Disable* bit is set, the X550 blocks new master requests by this function. The X550 then proceeds to issue any pending requests by this function. This bit is cleared on master reset (LAN\_PWR\_GOOD all the way to software reset) to allow master accesses.
- *PCIe Master Enable Status* bits in the Device Status register — Cleared by the X550 when the *PCIe Master Disable* bit is set and no master requests are pending by the relevant function. Set otherwise. Indicates that no master requests are issued by this function as long as the *PCIe Master Disable* bit is set. The following activities must end before the X550 clears the *PCIe Master Enable Status* bit:
  - Master requests by the transmit and receive engines
  - All pending completions to the X550 are received.

**Note:** The software device driver disables any reception to the Rx queues as described in [Section 4.6.7.1.1](#). Then, the software device driver sets the *PCIe Master Disable* bit when notified of a pending master disable (or D3 entry). The X550 then blocks new requests and proceeds to issue any pending requests by this function. The software device driver then reads the change made in the *PCIe Master Disable* bit and then polls the *PCIe Master Enable Status* bit. Once the bit is cleared, it is guaranteed that no requests are pending from this function.

The software device driver might time out if the *PCIe Master Enable Status* bit is not cleared within a given time. Examples for cases that the X550 might not clear the *PCIe Master Enable Status* bit for a long time are cases of flow control, link down, or DMA completions not making it back to the DMA block. In these cases, the software device driver should check that the *Transaction Pending* bit (bit 5) in the Device Status register in the PCI config space is cleared before proceeding. In such cases, the driver needs to clear internal buffers by:

- Setting the HLREG0.LPBK bit.
- Clearing RXCTRL.RXEN bit.
- Setting the setting GCR\_EXT.Buffers\_Clear\_Func bit for 20  $\mu$ s.
- Initiate two consecutive software resets with a delay larger than 1  $\mu$ s between them.

Intel's device driver software times-out at  $\sim 800$   $\mu$ s. The *PCIe Master Disable* bit must be cleared to enable master request to the PCIe link. This bit should be cleared through reset.

#### 5.2.4.4 Dr State

Transition to Dr state is initiated on several occasions:

- **On system power up** — Dr state begins with the assertion of the internal power detection circuit (LAN\_PWR\_GOOD) and ends with de-assertion of PE\_RST\_N.
- **On transition from a D0a state** — During operation the system might assert PE\_RST\_N at any time. In an ACPI system, a system transition to the G2/S5 state causes a transition from D0a to Dr state.
- **On transition from a D3 state** — The system transitions the device into the Dr state by asserting PCIe PE\_RST\_N.

Any wake-up filter settings that were enabled before entering this reset state are maintained.

The system might maintain PE\_RST\_N asserted for an arbitrary time. The de-assertion (rising edge) of PE\_RST\_N causes a transition to D0u state.

While in Dr state, the X550 might maintain functionality (for WoL or manageability) or might enter a Dr Disable state (if no WoL and no manageability) for minimal device power. The Dr Disable mode is described in the sections that follow.

##### 5.2.4.4.1 Dr Disable Mode

The X550 enters a Dr disable mode on transition to D3cold state when it does not need to maintain any functionality. The conditions to enter either state are:

- The device such as all PCI functions) is in Dr state.
- APM WoL is inactive for both LAN functions.
- Pass-through manageability is disabled.
- ACPI PME is disabled for all PCI functions.

Entry into Dr disable is usually done on assertion of PCIe PE\_RST\_N. It might also be possible to enter Dr disable mode by reading the NVM while already in Dr state. The usage model for this later case is on system power up, assuming that manageability and wake-up are not required. Once the X550 enters Dr state on power-up, the NVM is read. If the NVM contents determine that the conditions to enter Dr Disable are met, the X550 then enters this mode (assuming that PCIe PE\_RST\_N is still asserted).

Exit from Dr disable is through de-assertion of PCIe PE\_RST\_N.

If Dr disable mode is entered from D3 state, the platform might remove X550 power. If the platform removes X550 power, it must remove all power rails from the X550 if it needs to use this capability. Exit from this state is through power-up cycle to the X550.

#### 5.2.4.4.2 Entry to Dr State

Dr-entry on platform power-up is as follows:

- Asserting the internal power detection circuit (LAN\_PWR\_GOOD). Device power is kept to a minimum by keeping the PHYs in low power.
- The NVM is then read and determines device configuration.
- If the *APM Enable* bit in *NVM Control Word 3* is set, APM wake-up is enabled (for each port independently).
- Each of the LAN ports can be enabled if required for WoL or manageability. See [Section 5.3.5.2](#) for exact condition to enable a port. In such a case, the PHY might auto-negotiate to a lower speed on Dr entry (see [Section 5.3.5](#)).
- The PCIe link is not enabled in Dr state following system power up (since PE\_RST\_N is asserted).

Entry to Dr state from D0a state is by asserting the PE\_RST\_N signal. An ACPI transition to the G2/S5 state is reflected in a device transition from D0a to Dr state. The transition can be orderly (such as user selected a shut down operating system option), in which case the software device driver might have a chance to intervene. Or, it might be an emergency transition (like power button override), in which case, the software device driver is not notified.

To reduce power consumption, if any of manageability, APM wake or PCI-PM PME<sup>1</sup> is enabled, the PHY auto-negotiates to a lower link speed on D0a to Dr transition (see [Section 5.3.5](#)).

Transition from D3 state to Dr state is done by asserting the PE\_RST\_N signal. Prior to that, the system initiates a transition of the PCIe link from L1 state to either the L2 or L3 state (assuming all functions were already in D3 state). The link enters L2 state if PCI-PM PME is enabled.

---

1. ACPI 2.0 specifies that OSPM does not disable wake events before setting the *SLP\_EN* bit when entering the S5 sleeping state. This provides support for remote management initiatives by enabling Remote Power On (RPO) capability. This is a change from ACPI 1.0 behavior.

## 5.2.5 Timing of Power-State Transitions

The following sections give detailed timing for the state transitions. In the diagrams, the dotted connecting lines represent the X550 requirements, while the solid connecting lines represent the X550 guarantees.

Note that the timing diagrams are not to scale. The clock's edges are shown to indicate running clocks only and are not used to indicate the actual number of cycles for any operation.

### 5.2.5.1 Transition from D0a to D3 and Back without PE\_RST\_N

| No. | Notes                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | Writing 11b to the <i>Power State</i> field of the PMCSR transitions the X550 to D3. PHY re-negotiates to a lower link speed once <i>VE TO</i> bit is cleared if manageability and/or WoL is enabled, else it is powered down. When in power-down mode, PHY is reset and its CSRs are reset to their default values according to provisional register segment loaded from NVM at last LAN_PWR_GOOD event. |
| 2   | The system can keep the X550 in D3 state for an arbitrary amount of time.                                                                                                                                                                                                                                                                                                                                 |
| 3   | To exit D3 state the system writes 00b to the <i>Power State</i> field of the PMCSR.                                                                                                                                                                                                                                                                                                                      |
| 4   | APM wake-up or manageability might be enabled based on what is read in the NVM.                                                                                                                                                                                                                                                                                                                           |
| 5   | After reading the MAC section of the NVM, the LAN ports are enabled and the X550 transitions to D0u state. PHY re-negotiates to full link speed.                                                                                                                                                                                                                                                          |
| 6   | The system can delay an arbitrary time before enabling memory access.                                                                                                                                                                                                                                                                                                                                     |
| 7   | Writing a 1b to the <i>Memory Access Enable</i> bit or to the <i>I/O Access Enable</i> bit in the PCI Command register transitions the X550 from D0u to D0 state.                                                                                                                                                                                                                                         |

## 5.2.5.2 Transition from D0a to D3 and Back with PE\_RST\_N

| No. | Notes                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | Writing 11b to the <i>Power State</i> field of the PMCSR transitions the X550 to D3. PCIe link transitions to L1 state. PHY re-negotiates to a lower link speed once <i>VETO</i> bit is cleared if manageability and/or WoL is enabled, else it is powered down. When in power-down mode, PHY is reset and its CSRs are reset to their default values according to provisional register segment loaded from NVM at last LAN_PWR_GOOD event. |
| 2   | The system can delay an arbitrary amount of time between setting D3 mode and transitioning the link to an L2 or L3 state.                                                                                                                                                                                                                                                                                                                   |
| 3   | Following link transition, PE_RST_N is asserted.                                                                                                                                                                                                                                                                                                                                                                                            |
| 4   | The system must assert PE_RST_N before stopping the PCIe reference clock. It must also wait $t_{l2clk}$ after link transition to L2/L3 before stopping the reference clock.                                                                                                                                                                                                                                                                 |
| 5   | On assertion of PE_RST_N, the X550 transitions to Dr state. Once entering Dr state, if manageability and/or WoL is enabled, PHY re-negotiates a lower link speed in any case, even if the <i>VETO</i> bit is asserted, else it is maintained powered down.                                                                                                                                                                                  |
| 6   | The system starts the PCIe reference clock $t_{PWRGD-CLK}$ before de-assertion PE_RST_N.                                                                                                                                                                                                                                                                                                                                                    |
| 7   | The Internal PCIe clock is valid and stable $t_{ppg-clkint}$ from PE_RST_N de-assertion.                                                                                                                                                                                                                                                                                                                                                    |
| 8   | The PCIe Internal PWRGD signal is asserted $t_{clkpr}$ after the external PE_RST_N signal.                                                                                                                                                                                                                                                                                                                                                  |
| 9   | Assertion of Internal PCIe PWRGD causes the MAC section in the NVM to be re-read and disables wake-up. PHY is reset only if manageability unit and WoL are disabled. In such a case, PHY CSRs are reset to their default values according to provisional register segment loaded from NVM on last power-up event.                                                                                                                           |
| 10  | APM wake-up mode might be enabled based on what is read from the NVM. PHY re-negotiates to full link speed.                                                                                                                                                                                                                                                                                                                                 |
| 11  | Link training starts after $t_{pgtrn}$ from PE_RST_N de-assertion.                                                                                                                                                                                                                                                                                                                                                                          |
| 12  | A first PCIe configuration access might arrive after $t_{pgcfc}$ from PE_RST_N de-assertion.                                                                                                                                                                                                                                                                                                                                                |
| 13  | A first PCI configuration response can be sent after $t_{pgres}$ from PE_RST_N de-assertion.                                                                                                                                                                                                                                                                                                                                                |
| 14  | Writing a 1b to the <i>Memory Access Enable</i> bit in the PCI Command register transitions the device from D0u to D0 state.                                                                                                                                                                                                                                                                                                                |

### 5.2.5.3 Transition from D0a to Dr and Back without Transition to D3

| No. | Notes                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | The system must assert PE_RST_N before stopping the PCIe reference clock. It must also wait $t_{l2clk}$ after link transition to L2/L3 before stopping the reference clock.                                                                                                                                                                                                                                                                                                |
| 2   | On assertion of PE_RST_N, the X550 transitions to Dr state and the PCIe link transitions to electrical idle. Once entering Dr state, if manageability and/or WoL is enabled, PHY re-negotiates a lower link speed in any case, even if the <i>VETO</i> bit is asserted, else it is powered down. When in power-down mode, PHY is reset and its CSRs are reset to their default values according to provisional register segment loaded from NVM at last LAN_PWR_GOOD event |
| 3   | The system starts the PCIe reference clock $t_{PWRGD-CLK}$ before de-assertion PE_RST_N.                                                                                                                                                                                                                                                                                                                                                                                   |
| 4   | The Internal PCIe clock is valid and stable $t_{pgg-clkint}$ from PE_RST_N de-assertion.                                                                                                                                                                                                                                                                                                                                                                                   |
| 5   | The PCIe Internal PWRGD signal is asserted $t_{clkpr}$ after the external PE_RST_N signal.                                                                                                                                                                                                                                                                                                                                                                                 |
| 6   | Asserting Internal PCIe PWRGD causes the MAC section in the NVM to be re-read and disables wake-up. PHY is reset only if manageability unit and WoL are disabled. In such a case, PHY CSRs are reset to their default values according to provisional register segment loaded from NVM on last power-up event.                                                                                                                                                             |
| 7   | APM wake-up mode might be enabled based on what is read from the NVM.                                                                                                                                                                                                                                                                                                                                                                                                      |
| 8   | After reading the NVM, PHY re-negotiates to full link speed.                                                                                                                                                                                                                                                                                                                                                                                                               |
| 9   | Link training starts after $t_{pgtrn}$ from PE_RST_N de-assertion.                                                                                                                                                                                                                                                                                                                                                                                                         |
| 10  | A first PCIe configuration access might arrive after $t_{pgcfg}$ from PE_RST_N de-assertion.                                                                                                                                                                                                                                                                                                                                                                               |
| 11  | A first PCI configuration response can be sent after $t_{pgres}$ from PE_RST_N de-assertion.                                                                                                                                                                                                                                                                                                                                                                               |
| 12  | Writing a 1b to the <i>Memory Access Enable</i> bit in the PCI Command register transitions the device from D0u to D0 state.                                                                                                                                                                                                                                                                                                                                               |

## 5.2.5.4 Timing Requirements

The X550 requires the following start-up and power-state transitions.

**Table 5-1. Start-up and Power-State Transitions**

| Parameter              | Description                                                   | Min    | Max   | Notes                                            |
|------------------------|---------------------------------------------------------------|--------|-------|--------------------------------------------------|
| t <sub>xog</sub>       | Xosc stable from power stable.                                |        | 10 ms |                                                  |
| t <sub>PWRGD-CLK</sub> | PCIe clock valid to PCIe power good.                          | 100 μs | -     | According to PCIe specification.                 |
| t <sub>PVGL</sub>      | Power rails stable to PCIe PE_RST_N inactive.                 | 100 ms | -     | According to PCIe specification.                 |
| t <sub>pgcf</sub>      | External PE_RST_N signal to first configuration cycle.        | 100 ms |       | According to PCIe specification.                 |
| td0mem                 | Device programmed from D3h to D0 state to next device access. | 10 ms  |       | According to PCI power management specification. |
| tl2pg                  | L2 link transition to PE_RST_N assertion.                     | 0 ns   |       | According to PCIe specification.                 |
| tl2clk                 | L2 link transition to removal of PCIe reference clock.        | 100 ns |       | According to PCIe specification.                 |
| tclkpg                 | PE_RST_N assertion to removal of PCIe reference clock.        | 0 ns   |       | According to PCIe specification.                 |
| tpgdl                  | PE_RST_N assertion time.                                      | 100 μs |       | According to PCIe specification.                 |

## 5.2.5.5 Timing Guarantees

The X550 guarantees the following start-up and power state transition related timing parameters.

**Table 5-2. Start-up and Power-State Transition Timing Parameters**

| Parameter               | Description                                                 | Min   | Max      | Notes                            |
|-------------------------|-------------------------------------------------------------|-------|----------|----------------------------------|
| t <sub>xog</sub>        | Xosc stable from power stable.                              |       | 10 ms    |                                  |
| t <sub>ppg</sub>        | Internal power good delay from valid power rail.            | 35 ms | 35 ms    |                                  |
| t <sub>fl</sub>         | NVM read duration.                                          |       | 20 ms    |                                  |
| t <sub>ppg-clkint</sub> | PCIe PE_RST_N to internal PLL lock.                         | -     | 50 μs    |                                  |
| t <sub>clkpr</sub>      | Internal PCIe PWGD from external PCIe PE_RST_N.             |       | 50 μs    |                                  |
| tpgtrn                  | PCIe PE_RST_N to start of link training.                    |       | 20 ms    | According to PCIe specification. |
| tpgres                  | External PE_RST_N to response to first configuration cycle. |       | 1 second | According to PCIe specification. |

## 5.3 Network Interfaces Power Management

The X550 transitions any of the network interfaces into a low-power state in the following cases:

- The respective LAN function is in LAN disable mode using LANx\_DIS\_N pin.
- The X550 is in D3 or Dr state, APM WoL is disabled for the port, ACPI wake is disabled for the port and pass-through manageability is disabled for the port.

Use of the LAN ports for pass-through manageability follows the following behavior:

- If manageability is disabled (*Manageability Mode* field in the *Common Firmware Parameters* NVM word is set to None - [Section 6.5.2.2](#)), LAN ports are not allocated for manageability.
- If manageability is enabled:
  - Power-up — Following an NVM read, a single port is enabled for manageability, running at the lowest speed supported by the interface. If APM WoL is enabled on a single port, the same port is used for manageability. Otherwise, manageability protocols (such as teaming) determine which port is used.
  - D0 state — Both LAN ports are enabled for manageability.
  - D3 and Dr states — A single port is enabled for manageability, running at the lowest speed supported by the interface. If WoL is enabled on a single port, the same port is used for manageability. Otherwise, manageability protocols such as teaming) determine which port is used.

Enabling a port as a result of the previous behaviors cause an internal reset of the port including its associated PHY.

When a network interface is in low-power state, the X550 MAC asserts internal signals to notify the PHY that it must either power down as well or re-negotiate to a lower link speed.

### 5.3.1 PHY Power-Down State

Each X550 port enters a power-down state when none of its clients is enabled and therefore has no need to maintain a link. This can happen in one of the following cases:

1. **D3/Dr state** — Each PHY enters a low-power state if all the following conditions are met:
  - a. The LAN function associated with this PHY is in a non-D0 state
  - b. APM WoL is inactive
  - c. Manageability does not use this port
  - d. ACPI PME is disabled for this port
2. **LAN disable pin** — Each PHY is disabled if the associated LAN disable input pin indicates that the port should be disabled.
3. **LAN PCI Disable bit in NVM** — A single LAN port can also be disabled through NVM settings. If the *LAN PCI Disable* bit is set in *NVM Control Word 2*, and if the port is not used for WoL or for MC traffic, the *LAN Disable Select* bit selects the MAC and PHY port that enters power down even in D0 state. Note that if the port is used for WoL or by the MC, setting the *LAN PCI Disable* bit in *NVM Control Word 2* does not bring the MAC and PHY into power down, but only the DMA block.

When powered down by one of these means, a significant portion of the MAC and the PHY (including its microprocessor, MDIO, and interrupt logic) are powered down. Only the PHY PLLs are functioning, and the Analog Front-End (AFE) is turned off (gets placed in high-impedance mode).

When the X550 is completely powered down (Dr state), the PHYs reach a deeper power saving mode.

When the PHY exits power down, it re-initializes all analog functions, and retrieves the default configuration settings that were loaded from NVM the last time NVM was read.

### 5.3.2 PHY Power-Down via the PHY Register

The PHY can also be powered down by setting a *Low Power* bit in a PHY register (Global Standard Control 1: Address 1E.0, bit B). This bit powers down a significant portion of the PHY but clocks provided to the MAC and to the register section of the PHY remain active. Only the MDIO, interrupts, and microprocessor are functioning, and the AFE is turned off (gets placed in high-impedance mode). This enables the PHY management interface to remain active during register power down. Setting this bit also sets all of the *Low Power* bits in the other MMDs.

When the PHY exits software power down (*Low Power* bit cleared), it re-initializes all analog functions, but retains its previous configuration settings.

### 5.3.3 Smart Power-Down (SPD)

Smart Power-Down (SPD) is a feature that allows the PHY to enter a deep power saving state if it detects that the link is down for a long period of time. In this mode, the PHY does not transmit Link pulses. To detect a connection of a partner, the PHY periodically wakes up and sends link pulses for a short period of time to allow detection by the link partner. SPD is applicable to all power management states.

SPD combines a power-saving mechanism with the fact that the link might disappear and resume. Smart power-down is enabled by *Smart Power-Down Enable* PHY register field, which can be provisioned in the PHY NVM section, and is entered when the PHY detects link loss.

SPD is supported only when working in auto-negotiation mode, and not in parallel detect mode.

While in the smart power-down state, the PHY powers down circuits and clocks that are not required for detection of link activity. The PHY is still able to detect link pulses (including parallel detect) and wakeup to engage in link negotiation. The PHY does not send auto-negotiation words (FLP) while in SPD state unless configured to Deadlock-avoidance as defined in [Section 5.3.3.1](#). Register accesses to the PHY is still possible.

**Note:** Since some of the PHY blocks might be in power-down during SPD, Access to the registers of these blocks is not supported during SPD.

PHY indicates SPD-Status via the *Smart Power-Down Status* bit. This register is accessible to the MAC in all the PHY power-modes.

When the PHY is in smart power-down and detects link activity, it re-negotiates link speed based on the power state as in the normal case.

**Note:** The link-disconnect state applies to all power management states (Dr, D0u, D0a, D3). The link might change status, that is go up or go down, while in any of these states

See [Section 5.3.3.2](#) for details of the SPD control bit.

### 5.3.3.1 Deadlock Avoidance Mechanism (FLP)

While in link disconnect, the X550 monitors the link for Fast Link Pulses to identify when a link is reconnected. The X550 also periodically transmits pulses to resolve the case of two X550 (or devices with X550-like behavior) connected to each other across the link. Otherwise, two such devices might be locked in smart power-down mode, not capable of identifying that a link was re-connected. The link pulses are transmitted on average every 100 ms on alternate channels (A/B and C/D), and add negligible power to total X550 power at link disconnect mode.

Pulses might not conform to IEEE specification regarding link pulse template.

If the link partners are disconnected and then reconnected, it is possible that the two controllers transmit their pulses at the same time. Since the X550 might mask its receiver during pulse transmission, such synchronization causes pulses to be missed by both partners. A randomization factor is therefore applied to the timing of transmitted pulses, affecting the period between pulses. The randomization factor is specific per device and should reduce the probability of a lock to at least 10<sup>-4</sup>.

**Note:** If the two partners happen to transmit within the same slot, and if the randomization factor happens to be similar, it takes longer for the partners to get out of sync with each other.

Deadlock-Avoidance smart power-down is enabled by the *Deadlock Avoidance Enable* bit in the PHY registers. The default value is enabled. The *Enable* bit applies only while in smart power-down mode.

**Note:** The emission of FLP by the two ports of the X550 are not synchronized to avoid issues in tests where a link is established between the two ports.

### 5.3.3.2 SPD Control

The following bits in the PHY registers are used to control/monitor the SPD feature:

- Controls
  - *Deadlock Avoidance Enable* — Enables deadlock avoidance by transmitting FLP while in smart power down mode — 1E.C475.3 ([Section 10.6.18](#)).
  - *Smart Power-Down Enable* — 1E.C475.2 ([Section 10.6.18](#)).
  - *Smart Power-Down Entered Mask* (Enable interrupt generation) — The mask bit is to enable an interrupt to the MAC in case SPD was entered — 1E.D401.E ([Section 10.6.47](#)).
- Statuses
  - *Smart Power-Down Status* (active, inactive) — 1E.C475.D ([Section 10.6.18](#)).
  - *Smart Power-Down Entered* — When this bit is set, it indicates that the smart power down state was entered — 1E.CC01.E ([Section 10.6.44](#)).

**Note:** The *Smart Power-Down Entered* bit is self cleared when read, but it is set again by the next try of the Deadlock avoidance mechanism to establish a link.

### 5.3.3.3 Timing Definitions

When port is configure to SPD it should meet the following timing constraints:

**Table 5-3. SPD Timing Parameters**

| Parameter            | Description                                                                                                                                                       | Min   | Typ    | Max    | Remark                                                                                                        |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|--------|--------|---------------------------------------------------------------------------------------------------------------|
| $T_{\text{spd-in}}$  | Time elapsed from the Link-Disconnect event until Port actually enter into SPD mode.                                                                              | 2 sec |        | 10 sec |                                                                                                               |
| $T_{\text{spd-out}}$ | Time elapsed from the Link-Reconnect event (first link pulse arrives at package pins) until Port actually exit from SPD mode and start the auto-negotiation mode. | 70 ms |        | 100 ms |                                                                                                               |
| $T_{\text{b2b-flp}}$ | Time between two consecutive FLPs (Fast-Link-Pulses) transmitted by TVL during Deadlock-Avoidance mode.                                                           | 90 ms | 100 ms | 110 ms | The $T_{\text{b2b-flp}}$ Min/Max numbers include the randomization factor during the Deadlock-Avoidance mode. |

### 5.3.4 Disable 10GBASE-T and/or 1000BASE-T Speeds

To reduce power consumption of a port even when it is active, there is an option to disable 10 Gb/s and/or 1000 Mb/s advertisement during auto-negotiation.

This can be useful for cases where a copper link is used as a dormant link for redundancy purposes only.

These options are enabled by the following bits in PHY registers:

- Auto-Negotiation 10GBASE-T Control Register: Address 7.20, bit C - Disable 10 Gb/s in any state.
- Auto-Negotiation Vendor Provisioning 1: Address 7.C400, bit F - Disable 1000 Mb/s in any state.

**Note:** These bits disable the advertisement of a speed in any power state, whether the port is active (D0u or D0a) or in low power (Dr or D3).

### 5.3.5 Low Power Link Up (LPLU)

The PHY is aware of power management states. If the PHY is not in a power down state, PHY behavior regarding several features are different depending on the device or port power state. The internal PHY power state is controlled internally from the MAC.

Normal PHY speed negotiation drives to establish a link at the highest possible speed. The PHY supports an additional mode of operation, where the PHY drives to establish a link at a low speed. The LPLU process enables a link to come up at the lowest possible speed in cases where power is more important than performance. Different behavior is defined for the D0 state and the other non-D0 states.

Table 5-4 lists link speed as function of power management state, link speed control, and GbE speed enabling:

**Table 5-4. Link Speed vs. Power State**

| Power State | LPLU Bit in NVM | Disable Bits in NVM         |                            | Disable Bits in Register    |                            | PHY Speed Negotiation                                                                |
|-------------|-----------------|-----------------------------|----------------------------|-----------------------------|----------------------------|--------------------------------------------------------------------------------------|
|             |                 | Disable 10 GbE in LPLU Mode | Disable 1 GbE in LPLU Mode | Disable 10 GbE in Any State | Disable 1 GbE in Any State |                                                                                      |
| D0          | X               | X                           | X                          | 0b                          | 0b                         | PHY advertises 10 GbE, 1 GbE, 100 Mb/s                                               |
|             |                 |                             |                            | 1b                          | 0b                         | PHY advertises 1 GbE and 100 Mb/s only.                                              |
|             |                 |                             |                            | 0b                          | 1b                         | PHY advertises 10 GbE and 100 Mb/s only.                                             |
|             |                 |                             |                            | 1b                          | 1b                         | PHY advertises 100 Mb/s only.                                                        |
| Non-D0      | 0b              | X                           | X                          | 0b                          | 0b                         | PHY advertises 10 GbE, 1 GbE, 100 Mb/s                                               |
|             |                 |                             |                            | 1b                          | 0b                         | PHY advertises 1 GbE and 100 Mb/s only.                                              |
|             |                 |                             |                            | 0b                          | 1b                         | PHY advertises 10 GbE and 100 Mb/s only.                                             |
|             |                 |                             |                            | 1b                          | 1b                         | PHY advertises 100 Mb/s only.                                                        |
|             | 1b              | 0b                          | 0b                         | 0b                          | 0b                         | PHY goes through LPLU procedure, starting from 100 Mb/s, up to 1 GbE and 10 GbE.     |
|             |                 |                             |                            | 1b                          | 0b                         | PHY goes through LPLU procedure, starting from 100 Mb/s and followed by 1 GbE only.  |
|             |                 |                             |                            | 0b                          | 1b                         | PHY goes through LPLU procedure, starting from 100 Mb/s and followed by 10 GbE only. |
|             |                 |                             |                            | 1b                          | 1b                         | PHY advertise 100 Mb/s only.                                                         |
|             |                 | 1b                          | 0b                         | X                           | 0b                         | PHY goes through LPLU procedure, starting from 100 Mb/s and followed by 1 GbE.       |
|             |                 |                             |                            | X                           | 1b                         | PHY advertises 100 Mb/s only.                                                        |
|             |                 |                             |                            | X                           | X                          | PHY advertises 100 Mb/s only.                                                        |
|             |                 |                             |                            | X                           | X                          | N/A (non supported setting)                                                          |

X means Don't care.

LPLU bit in NVM - Refers to *NVM Control Word 3*, bit 3, shared by both ports.

Disable 10 GbE in LPLU mode - Refers to *NVM Control Word 3*, bits 6 and 8, one bit per port.

Disable 1 GbE in LPLU mode - Refers to *NVM Control Word 3*, bits 5 and 7, one bit per port.

Disable 10 GbE any state - Refers to PHY register 7.20[C].

Disable 1 GbE any state - Refers to PHY register 7.C400[F].

**Notes:** The software device driver is responsible to re-start auto-negotiation when it changes the setting of the *Disable 10 GbE* or *1 GbE* bits in the PHY register.

For proper LPLU functionality, *Upshift-Enabled* bit must be set in the PHY at register 7.C411.0 (default is 1b, enabled).

If manageability and WoL are both disabled, the directives of [Table 5-4](#), when in non-D0 state, are not relevant as the PHY port is disabled.

### 5.3.5.1 Behavior in Non-D0 State

If the *LPLU* bit is set in the NVM, the PHY negotiates to a low speed while in non-D0 states (Dr or D3). This applies only when the link is required by one of the following: SMBus or NC-SI manageability, APM wake, or PME. Otherwise, the PHY is disabled during the non-D0 state.

Link negotiation begins with the PHY trying to negotiate at the lowest speed it is allowed to advertise, as listed in [Table 5-4](#). If link establishment fails, the PHY tries to negotiate at additional speeds, such as all speeds allowed up to the lowest speed supported by the partner. For example, the PHY advertises 100 Mb/s only and the partner supports 1000 Mb/s only. After the first try fails, PHY enables 100/1000 Mb/s and tries again. The PHY continues to try and establish a link until it succeeds or until it is instructed otherwise.

**Note:** Automatic MDI/MDI-X resolution is done during the first auto-negotiation stage.

### 5.3.5.2 Link Speed Change vs. Power Mode

Normal speed negotiation drives to establish a link at the Highest Common Denominator (HCD) link speed. The X550 supports an additional mode of operation, where the PHY establishes a link at the Lowest Common Denominator (LCD) link speed. The LPLU process allows a link to come up at any possible speed in cases where power is more important than performance. Different behavior is defined for the D0 state and non-D0 states as a function of the *D10GMP*, *D1GMP* bits in the NVM and of the *MMNGC.MNG\_VETO* register bit.

The X550 initiates auto-negotiation without a direct software device driver command in the following cases:

- When the state of *MAIN\_PWR\_OK* pin changes.
- When the *MNG\_VETO* bit value changes.
- On a transition from D0 state to a non-D0 state, or from a non-D0 state to D0 state.

During a manageability session, any change in a power management state must not cause the Ethernet link to drop because the manageability session will be lost. Therefore in such a case the Ethernet link speed should be kept unchanged. For example, the transition to D3hot state is not propagated to the PHY as long as a manageability session exists.

**Note:** However, if main power is removed, the PHY is allowed to react to the change in power state (such as the PHY might respond in link speed change). The motivation for this exception is to reduce power when operating on auxiliary power by reducing link speed.

The capability of masking from the PHY the changes that occur in a power management state is enabled by default on *LAN\_PWR\_GOOD* reset. The *Keep\_PHY\_Link\_Up\_En* bit in *NVM Control Word 3 - Offset 0x38* word must be cleared to disable it. Once enabled, the feature is enabled until the next *LAN\_PWR\_GOOD* (such as the X550 does not revert to the hardware default value on *PE\_RST\_N*, PCIe reset, or any other reset but *LAN\_PWR\_GOOD*).

Existence of a manageability session is identified by the *MNG\_VETO* bit set in the *MMNGC* register.

The *MNG\_VETO* bit is set by the MC through the Management Control command (see [Section 11.5.11.1.5](#) for SMBus command and [Section 11.6.3.12](#) for NC-SI command) on the sideband interface. It is cleared by the external MC (also through a command on the sideband interface) when the manageability session ends.

The *MNG\_VETO* bit becomes meaningless when de-asserting the *MAIN\_PWR\_OK* input pin. *MAIN\_PWR\_OK* must be de-asserted at least 10 ms before power drops below its 90% value. This allows enough time to the PHY to drop the link and restart auto-negotiation before auxiliary power takes over. Note that since auto-negotiation is restarted, the PHY power consumption is already cut down.

Figure 5-2 shows the X550 behavior when entering low power mode:

Figure 5-2. Link Speed Change when Entering Power-Down Mode

Figure 5-3 shows the X550 behavior when going to power-up mode.

**Figure 5-3. Link Speed Change when Entering Power-Up Mode**

**Notes:** To simplify things, the impact of the *LPLU* and *Keep\_PHY\_Link\_Up\_En* bits in the *NVM Control Word 3* is not shown in the flow charts because these bits are assumed to be set. If the *Keep\_PHY\_Link\_Up\_En* bit is cleared, the *VETO* bit set condition always returns NO.

The same remark for the impact of the *Disable Speed* bits described in [Section 5.3.4](#), which are assumed to be cleared.

The PHY re-negotiates full line speed once exiting power down state, without waiting for the *Memory Access Enable* bit of the PCIe Command register to be written.

## 5.3.6 Energy Efficient Ethernet (EEE)

the X550 enters EEE Low Power Idle (LPI) mode on transmit or receive independently each time the X550 detects no data is scheduled for transmission, or the link partner indicates no data is pending for reception.

EEE LPI mode defined in IEEE802.3az enables power saving by switching off part of the X550 functionality when no data needs to be transmitted or/and received. Decision on whether the X550 transmit path should enter LPI mode or exit LPI mode is done according to a need to transmit. Information on whether a link partner has entered LPI mode is detected by the X550 and utilized for power saving in the receive circuitry.

When no data needs to be transmitted, a request to enter transmit LPI is issued on the internal xxMII Tx interface causing the PHY to transmit sleep symbols for a predefined period of time followed by a quiet period. During LPI, the PHY periodically transmits refresh symbols that are used by the link partner to update adaptive filters and timing circuits to maintain link integrity. This quiet-refresh cycle continues until transmitting 'normal inter-frame' encoding on the internal xxMII Tx interface. The PHY communicates to the link partner the move to link active state by sending wake symbols for a predefined period of time. The PHY then enters a normal operating state where data or idle symbols are transmitted.

In the receive direction, entering LPI mode is triggered by receiving sleep symbols from the link partner. This signals that the link partner is about to enter LPI mode. After sending the sleep symbols, the link partner ceases transmission. When the link partner initiates the move to LPI, the PHY indicates "assert low power idle" on the internal xxMII Rx interface and the X550 receiver disables functionality to reduce power consumption.

Figure 5-4 and Table 5-5 illustrate the general principles of EEE LPI operation on the Ethernet link.

Figure 5-4. EEE Operation

Table 5-5. EEE Parameters

| Parameter                                         | Description                                                                                              |
|---------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| Sleep Time ( $T_s$ )                              | Duration PHY sends sleep symbols before going quiet.                                                     |
| Quiet Duration ( $T_q$ )                          | Duration PHY remains quiet before it must wake for refresh period.                                       |
| Refresh Duration ( $T_r$ )                        | Duration PHY sends refresh symbols for timing recovery and coefficient synchronization.                  |
| PHY Wake Time ( $T_{w\_PHY}$ )                    | Minimum duration PHY takes to resume to active state after decision to wake.                             |
| Receive System Wake Time ( $T_{w\_System\_rx}$ )  | Wait period where no data is expected to be received to give the local receiving system time to wake-up. |
| Transmit System Wake Time ( $T_{w\_System\_tx}$ ) | Wait period where no data is transmitted to give the remote receiving system time to wake-up.            |

### 5.3.6.1 Conditions to Enter EEE Tx LPI

In the transmit direction entry into EEE LPI mode of operation is triggered when one of the following conditions exist:

1. No transmission is pending, management does not need to transmit and internal transmit buffer is empty and the `EEER.TX_LPI_EN` bit is set to 1b. If the `EEER.TX_LPI_EN` bit is set to 1b and a XOFF flow control packet is received from the link partner or PFC XOFF are received for all the traffic classes supporting PFC, the X550 moves the link into the Tx LPI state for the pause duration even if a transmission is pending.
2. When `EEER.FORCE_TLPI` is set (even if `EEER.TX_LPI_EN` is cleared).
  - If `EEER.FORCE_TLPI` is set in mid-packet, the X550 completes the packet transmission and moves Tx to LPI.

When one of the previous conditions to enter Tx LPI state are detected “assert LPI” is transmitted on the internal xxMII interface and the X550 PHY transmits sleep symbols on the network interface to communicate to the link partner entry into Tx LPI link state. After sleep symbols transmission, the PHY immediately enters the low power quiet mode. In this state the PHY periodically transitions between quiet link state, where link is idle, to sending refresh symbols until a request to transition link back to normal (active) mode is transmitted on the internal xxMII Tx interface (See [Figure 5-4](#)).

**Note:** Initial `EEER.TX_LPI_EN` configuration is loaded from NVM ([Table 6-4](#)).

**Note:** 10GBASE-T Ethernet LPI allows each link direction to enter sleep, refresh or wake states asymmetric from the other direction.

**Note:** EEE LPI status of a X550 port can be found in the `EEE_STAT` register.

### 5.3.6.2 Transition from Tx LPI to Active Link State

The X550 exits Tx LPI link state and transition link into active link state when none of the conditions defined in [Section 5.3.6.1](#) exist. To transition into active link state, the X550 transmits:

1. Normal ‘inter-frame’ encoding on the internal xxMII Tx interface for a pre-defined link rate dependent period time of `Tw_sys_tx-min` (defined by the `EEE_SU` register and IEEE802.3az clause 78.5). As a result, the PHY transmits wake symbols for a `Tw_phy` duration followed by idle symbols.
2. If the `Tw_System_tx` duration defined in the `EEER.TW_SYSTEM` field is longer than `Tw_sys_tx-min`, the X550 continues transmitting the ‘inter-frame’ encoding on the internal xxMII interface until the time defined in the `EEER.TW_SYSTEM` field has expired, before transmitting the actual data. During this period the PHY continues transmitting idle symbols.

**Note:** When moving out of Tx LPI to transmit a 802.3x flow control frame, the X550 waits for the `Tw_sys_tx-min` duration before transmitting the flow control frame. It should be noted that even in this scenario actual data is transmitted only after the `Tw_System_tx` time defined in the `EEER.TW_SYSTEM` field has expired.

### 5.3.6.3 EEE Auto-Negotiation

Auto-negotiation provides the capability to negotiate EEE capabilities with the link partner using the next page mechanism defined in IEEE802.3 Annex 73A. IEEE802.3 auto-negotiation is performed at power up, on command from software, upon detection of a PHY error or following link re-connection.

During the link establishment process, both link partners indicate their EEE capabilities using IEEE802.3 auto-negotiation. If EEE is supported by both link partners for the negotiated PHY type, the EEE function can be used independently in either direction.

### 5.3.6.4 EEE Link Level (LLDP) Capabilities Discovery

The X550 supports LLDP negotiation via software using the EEE IEEE802.1AB Link Layer Discovery Protocol (LLDP) Type, Length, Value (TLV) fields defined in IEEE802.3az clause 78 and clause 79. LLDP negotiation enables negotiation of increased system wake time (Transmit  $T_w$  and Receive  $T_w$ ) to enable improving system energy efficiency.

#### 5.3.6.4.1 LLDP Negotiation Actions

Following negotiation of a new system wake time via EEE LLDP negotiation, the following fields and registers should be updated:

The `EEER.TW_SYSTEM` field with the negotiated Transmit  $T_w$  time value, to increase the duration where idle symbols are transmitted following a move out of EEE Tx LPI state before actual data can be transmitted.

- A value placed in `EEER.TW_SYSTEM` field does not effect transmission of flow control packets. Depending on the technology flow control packet, transmission is delayed following a move out of EEE Tx LPI state only by the minimum `Tw_sys_tx` time as defined in IEEE802.3az clause 78.5. In the X550 the minimum `Tw_sys_tx` time value is defined in the `EEE_SU` register together with time defined in IEEE802.3az clause 78.5. Value varies as a function of link rate and technology.

### 5.3.6.5 EEE Statistics

The X550 supports reporting a number of EEE LPI Tx and Rx events via the RLPIC and TLPIC registers.

## 5.4 Wake-Up

### 5.4.1 Advanced Power Management Wake-Up

Advanced power management wake-up, or APM wake-up, was previously known as Wake on LAN (WoL). It is a feature that has existed in the 10/100 Mb/s NICs for several generations. The basic premise is to receive a packet with an explicit data pattern, and then to assert a signal to wake-up the system. In the earlier generations, this was accomplished by using a special signal that ran across a cable to a defined connector on the motherboard. The NIC asserts the signal for approximately 50 ms to signal a wake-up. The X550 uses (if configured to) an in-band PM\_PME message for this.

At power up, the X550 reads the *APM Enable* bit from the NVM into the *APM Enable* (*APME*) bits of the GRC register. This bit control the enabling of *APM Wakeup*.

When *APM Wakeup* is enabled and when not in D0 state, the X550 checks all incoming packets for Magic Packets. See [Section A.1.3](#) for a definition of Magic Packets.

Once the X550 receives a matching magic packet, it:

- Sets the *PME\_Status* bit in the *PMCSR* and issues a PM\_PME message (in some cases, this might require to assert the *PE\_WAKE\_N* signal first to resume power and clock to the PCIe interface).

**Note:** At wake-up from first power on, the PM\_PME message is not sent.

- Stores the first 128 bytes of the packet in the Wake-Up Packet Memory (WUPM).
- Sets the *Magic Packet Received* bit (*MAG*) in the Wake-Up Status (WUS) register.
- Sets the packet length in the Wake-Up Packet Length Register (WUPL).

The X550 maintains the first magic packet received in the Wake-Up Packet Memory (WUPM) until the software device driver writes a 0b to the Magic Packet Received *MAG* bit in the Wake-Up Status Register (WUS), hence the software device driver has to read the packet from WUPM prior to clearing the WUS indication.

*APM Wakeup* event is issued only when in Dx power states and it is disabled only if a subsequent NVM read results in the *APM Wake-Up* bit being cleared or if the software explicitly writes a 0b to the *APM Wake-Up* (*APM*) bit of the GRC register.

### 5.4.2 ACPI Power Management Wake-Up

The X550 supports ACPI power management based wake-up. It can generate system wake-up events from three sources, regardless to the power state:

- Receiving a Magic Packet.
- Receiving a network wake-up packet.
- Detecting a link change of state.
- Firmware reset event.

Activating ACPI power management wake-up requires the following steps:

- The operating system (at configuration time) writes a 1b to the *PME\_En* bit of the *PMCSR* (*PMCSR.8*).

- The software device driver clears all pending wake-up status in the WUS register by writing 1b to all the status bits.
- The software device driver programs the WUFC register to indicate the packets it needs to wake-up and supplies the necessary data to the IPv4/v6 Address Table (IP4AT, IP6AT), Flexible Host Filter Table (FHFT). It can also set the *Link Status Change Wake-Up Enable (LNKC)* bit in the WUFC register to cause wake-up when the link changes state.
- Once the X550 wakes the system the software device driver needs to clear the WUS and WUFC registers until the next time the system goes to a low power state with wake-up.

Normally, after enabling ACPI wake-up, the operating system writes (11b) to the lower two bits of the PMCSR to put the X550 into low-power mode, and once entering D0, OS disables ACPI wake-up.

Once wake-up is enabled, the X550 monitors incoming packets, first filtering them according to its standard address filtering method, then filtering them with all of the enabled wake-up filters. If a packet passes both the standard address filtering and at least one of the enabled wake-up filters, the X550:

- Sets the *PME\_Status* bit in the PMCSR.
- If the *PME\_En* bit in the PMCSR is set and device is in Dr state or *PCI\_GLBL\_CNF.WAKE\_PIN\_EN* is set in all states, asserts *PE\_WAKE\_N*.
- In non Dr state or when exiting Dr, a *PM\_PME* message is also issued.
- Stores the first 128 bytes of the packet in the Wake-Up Packet Memory (WUPM) register. Sets one or more of the *Received* bits in the WUS register. Note that the X550 sets more than one bit if a packet matches more than one filter. Sets the packet length in the Wake-Up Packet Length Register (WUPL).

If enabled, a link state change wake-up causes similar results, setting *PME\_Status*, asserting *PE\_WAKE\_N* and setting the *LNKC* bit in the WUS register when the link goes up or down.

**Note:** As the LPLU mechanism may cause a link change when entering Sx, setting the link state change wake-up while link is up may cause an immediate wake-up when entering Sx. If this is needed, the software device driver should move the link to the lowest available link speed before enabling the wake-up event and entering Sx.

If enabled, a firmware reset causes similar results, setting *PME\_Status*, asserting *PE\_WAKE\_N* and setting the *FW\_RST\_WK* bit in the WUS register when the firmware is reset.

*PE\_WAKE\_N* remains asserted until the operating system either writes a 1b to the *PME\_Status* bit of the PMCSR register or writes a 0b to the *PME\_En* bit.

### 5.4.3 Wake-Up Packets

The X550 supports various wake-up packets using two types of filters:

- Pre-defined filters
- Flexible filters

Each of these filters are enabled if the corresponding bit in the WUFC register is set to 1b.

### 5.4.3.1 Pre-Defined Filters

The following packets are supported by the X550's pre-defined filters:

- Directed packet (including exact, multicast indexed, and broadcast)
- Magic Packet
- ARP/IPv4 request packet
- Directed IPv4 packet
- Directed IPv6 packet

Each of these filters are enabled if the corresponding bit in the WUFC register is set to 1b.

The description of each filter includes a table showing which bytes at which offsets are compared to determine if the packet passes the filter. Both VLAN frames and LLC/SNAP can increase the given offsets if they are present.

#### 5.4.3.1.1 Directed Packets

**Unicast** — The X550 generates a wake-up event after receiving any packet whose destination address matches one of the 128 valid programmed receive addresses if the *Directed Exact Wake-Up Enable* bit is set in the WUFC register (WUFC.EX).

For multicast packets, the upper bits of the incoming packet's destination address index a bit vector, the Multicast Table Array (MTA) that indicates whether to accept the packet. If the *Directed Multicast Wake-Up Enable* bit set in the WUFC register (WUFC.MC) and the indexed bit in the vector is one, the X550 generates a wake-up event. The exact bits used in the comparison are programmed by software in the *Multicast Offset* field of the Multicast Control register (MCSTCTRL.MO).

If the *Broadcast Wake-Up Enable* bit in the WUFC register (WUFC.BC) is set, the X550 generates a wake-up event when it receives a broadcast packet.

#### 5.4.3.1.2 Magic Packet

See [Section A.1.3](#) for a definition of Magic Packets.

A Magic Packet's destination address must match the address filtering enabled in the configuration registers with the exception that broadcast packets are considered to match even if the *Broadcast Accept* bit of the Receive Control register (FCTRL.BAM) is 0b. If *APM Wakeup* is enabled in the NVM, the X550 starts up with the Receive Address Register 0 (RAH0, RAL0) loaded from the NVM. This enables the X550 to accept packets with the matching IEEE address before the software device driver comes up.

**Note:** Setting the FCTRL.MPE does not allow reception of magic packets with a multicast address. To receive such packets, the multicast address should be stored in an RHA/RAL register or enabled in the MTA table.

| Offset | # of Bytes | Field                        | Value | Action  | Comment                                             |
|--------|------------|------------------------------|-------|---------|-----------------------------------------------------|
| 0      | 6          | Destination Address          |       | Compare | MAC header – processed by main address filter       |
| 6      | 6          | Source Address               |       | Skip    |                                                     |
| 12     | S= (0/4)   | Possible VLAN Tag            |       | Skip    |                                                     |
| 12/16  | D=(0/8)    | Possible Len/LLC/SNAP Header |       | Skip    |                                                     |
| 12+S+D | 2          | Type                         |       | Skip    |                                                     |
| Any    | 6          | Synchronizing Stream         | FF*6+ | Compare |                                                     |
| any+6  | 96         | 16 Copies of Node Address    | A*16  | Compare | Compared to Receive Address Register 0 (RAH0, RAL0) |

#### 5.4.3.1.3 ARP/IPv4 Request Packet

The X550 supports receiving ARP request packets for wake-up if the *ARP* bit is set in the WUFC register. Four IPv4 addresses are supported, which are programmed in the IPv4 Address Table (IP4AT). A successfully matched packet must pass L2 address filtering, a Protocol Type of 0x0806, an ARP OpCode of 0x01, and one of the four programmed IPv4 addresses. The X550 also handles ARP request packets that have VLAN tagging on both Ethernet II and Ethernet SNAP types.

| Offset | # of Bytes | Field                        | Value  | Action  | Comment                                       |
|--------|------------|------------------------------|--------|---------|-----------------------------------------------|
| 0      | 6          | Destination Address          |        | Compare | MAC header – processed by main address filter |
| 6      | 6          | Source Address               |        | Skip    |                                               |
| 12     | S=(0/4)    | Possible VLAN Tag            |        | Compare |                                               |
| 12/16  | D=(0/8)    | Possible Len/LLC/SNAP Header |        | Skip    |                                               |
| 12+S+D | 2          | Type                         | 0x0806 | Compare | ARP                                           |
| 14+S+D | 2          | Hardware Type                | 0x0001 | Compare |                                               |
| 16+S+D | 2          | Protocol Type                | 0x0800 | Compare |                                               |
| 18+S+D | 1          | Hardware Size                | 0x06   | Compare |                                               |
| 19+S+D | 1          | Protocol Address Length      | 0x04   | Compare |                                               |
| 20+S+D | 2          | Operation                    | 0x0001 | Compare |                                               |
| 22+S+D | 6          | Sender Hardware Address      | -      | Ignore  |                                               |
| 28+S+D | 4          | Sender IP Address            | -      | Ignore  |                                               |
| 32+S+D | 6          | Target Hardware Address      | -      | Ignore  |                                               |
| 38+S+D | 4          | Target IP Address            | IP4AT  | Compare | Can match any of 4 values in IP4AT            |

#### 5.4.3.1.4 Directed IPv4 Packet

The X550 supports receiving directed IPv4 packets for wake-up if the *IPv4* bit is set in the WUFC register. Four IPv4 addresses are supported that are programmed in the IPv4 Address Table (IP4AT). A successfully matched packet must pass L2 address filtering, a Protocol Type of 0x0800, and one of the four programmed IPv4 addresses. The X550 also handles directed IPv4 packets that have VLAN tagging on both Ethernet II and Ethernet SNAP types.

### 5.4.3.1.5 Directed IPv6 Packet

The X550 supports receiving directed IPv6 packets for wake-up if the *IPV6* bit is set in the WUFC register. One IPv6 address is supported and it is programmed in the IPv6 Address Table (IP6AT). A successfully matched packet must pass L2 address filtering, a Protocol Type of 0x0800, and the programmed IPv6 address. The X550 also handles directed IPv6 packets that have VLAN tagging on both Ethernet II and Ethernet SNAP types.

### 5.4.3.2 Flexible Filter

The X550 supports a total of **eight** host flexible filters. Each filter can be configured to recognize any arbitrary pattern within the first 128 bytes of the packet. To configure the flexible filter, software programs the required values into the Flexible Host Filter Table (FHFT\_FILTER). These contain separate values for each filter. Software must also enable the filter in the WUFC register, and enable the overall wake-up functionality must be enabled by setting *PME\_En* in the PMCS register or the WUC register.

Structure of the Flexible Host Filter Table:

| 31       | 0 | 31       | 8 | 7            | 0 | 31   | 0 | 31   | 0 |
|----------|---|----------|---|--------------|---|------|---|------|---|
| Reserved |   | Reserved |   | Mask [7:0]   |   | DW 1 |   | DW 0 |   |
| Reserved |   | Reserved |   | Mask [15:8]  |   | DW 3 |   | DW 2 |   |
| Reserved |   | Reserved |   | Mask [23:16] |   | DW 5 |   | DW 4 |   |
| Reserved |   | Reserved |   | Mask [31:24] |   | DW 7 |   | DW 6 |   |

...

| 31       | 7 | 6        | 0 | 31       | 8 | 7              | 0 | 31    | 0 | 31    | 0 |
|----------|---|----------|---|----------|---|----------------|---|-------|---|-------|---|
| Reserved |   | Reserved |   | Reserved |   | Mask [127:120] |   | DW 29 |   | DW 28 |   |
| Reserved |   | Length   |   | Reserved |   | Mask [127:120] |   | DW 31 |   | DW 30 |   |

Each of the filters is allocated addresses as follows:

- Filter 0 — 0x09000 — 0x090FF
- Filter 1 — 0x09100 — 0x091FF
- Filter 2 — 0x09200 — 0x092FF
- Filter 3 — 0x09300 — 0x093FF
- Filter 4 — 0x09600 — 0x096FF
- Filter 5 — 0x09700 — 0x097FF
- Filter 6 — 0x09800 — 0x098FF
- Filter 7 — 0x09900 — 0x099FF

The following table lists the addresses used for filter 0.

| Field                  | Dword | Address | Bit(s) | Initial Value |
|------------------------|-------|---------|--------|---------------|
| Filter 0 DW0           | 0     | 0x09000 | 31:0   | X             |
| Filter 0 DW1           | 1     | 0x09004 | 31:0   | X             |
| Filter 0 Mask[7:0]     | 2     | 0x09008 | 7:0    | X             |
| Reserved               | 3     | 0x0900C |        | X             |
| Filter 0 DW2           | 4     | 0x09010 | 31:0   | X             |
| ...                    |       |         |        |               |
| Filter 0 DW30          | 60    | 0x090F0 | 31:0   | X             |
| Filter 0 DW31          | 61    | 0x090F4 | 31:0   | X             |
| Filter 0 Mask[127:120] | 62    | 0x090F8 | 7:0    | X             |
| Length                 | 63    | 0x090FC | 6:0    | X             |

Accessing the FHFT\_FILTER registers during filter operation might result in a packet being mis-classified if the write operation collides with packet reception. It is therefore advised that the flex filters are disabled prior to changing their setup.

Once enabled, the flexible filters scan incoming packets for a match. If the filter encounters any byte in the packet where the mask bit is one and the byte does not match the byte programmed in the Flexible Host Filter Table (FHFT\_FILTER), the filter fails that packet. If the filter reaches the required length without failing the packet, it passes the packet and generates a wake-up event. It ignores any mask bits set to one beyond the required length.

Packets that passed a wake-up flexible filter should cause a wake-up event only if it is directed to the X550 (passed L2 and VLAN filtering).

**Note:** The flexible filters are temporarily disabled when read from or written to by the host. Any packet received during a read or write operation is dropped. Filter operation resumes once the read or write access is done.

### 5.4.3.3 Wake-Up Packet Storage

The X550 saves the first 128 bytes of the wake-up packet in its internal buffer, which can be read through the Wake-Up Packet Memory (WUPM) after the system wakes up.

### 5.4.4 Wake-Up and Virtualization

When operating in a virtualized environment, all wake-up capabilities are managed by a single entity (such as the VMM or an IOVM). In an IOV architecture, the physical software device driver controls wake-up and none of the Virtual Machines (VMs) has direct access to the wake-up registers. The wake-up registers are not replicated.

## 5.5 DMA Coalescing

The X550 supports DMA coalescing that enables synchronizing port activity and optimizes power consumption of memory and CPU usage. DMA coalescing is a device-based feature and when the conditions to enter DMA coalescing operating mode exists (as defined in [Section 5.5.2.1](#)), the X550:

- Stops initiation of any activity on the PCIe link. This includes all the DMA transactions and MCTP VDMs (if `DMACR.EN_MNG_IND` is set).
- Buffers data received from the Ethernet link in internal Rx buffer until the conditions defined in [Section 5.5.2.2](#) to exit DMA coalescing exist. If `DMACR.EN_MNG_IND` is set, MCTP pass-through traffic is buffered also.

### 5.5.1 DMA Coalescing Activation

Activating DMA coalescing functionality is done by the software device driver. The software device driver can enable or disable the device DMA coalescing functionality by clearing the `DMACR.DMAC_EN` bit.

To activate DMA coalescing functionality the following fields need to be programmed:

1. `DMCTH.DMACRXT` fields to set the per Rx packet buffer receive threshold that causes the X550 to move out of DMA coalescing operating mode. When the amount of data in the receive packet buffer exceeds the receive threshold, the X550 moves out of DMA coalescing operating mode. A programmed receive watermark should take into account the actual link speed, Latency Tolerance Reported (LTR) and L1/L0s to L0 latency to avoid receive buffer overflow when DMA coalescing is enabled. See LTR description in [Section 5.6](#).
2. `DMACR.DMACWT` field to define a maximum time-out value for:
  - a. A receive packet to be stored in the internal receive buffer before the X550 moves a packet to host memory.
    - Each time the X550 enters DMA coalescing, an internal DMA coalescing watchdog timer is re-armed with the value placed in `DMACR.DMACWT`. When in DMA coalescing, the internal watchdog timer starts to count when one of the following conditions occurs:
      - An incoming Rx packet is received.
      - An MCTP transaction is pending.
      - An interrupt is pending.
  - b. Once an interval defined in the `DMACR.DMACWT` field has passed, the X550 exits DMA coalescing, internal buffers are flushed, RSC flows are closed and interrupts are flushed.
3. `DMCTLX.TTLX` timer field to define the time between detection of DMA idle condition and entry into DMA coalescing state. To limit entry into DMA coalescing state when packet rate is high.
4. `DMACR.DMAC_EN` bit should be set to 1b to enable activating DMA coalescing operating mode.
5. `DMACR.LX_COALESCING_INDICATION` bit defines whether to move in/out of DMA coalescing when the PCIe block moves in/out of L1/L0s, when set to 1b, DMA coalescing conditions are met only when PCIe is in L1/L0s, when set to 0b DMA coalescing can also start in L0. In addition, when the bit is set to 0b, DMA coalescing stops when any TLP transactions are executed on the PCIe.
6. `DMACR.EN_MNG_IND` bit should be set to 1b to enable a management indication impact on DMA coalescing mode. This bit also enables a DMA coalescing impact on MCTP over PCIe traffic.

7. `DMCMNGTH.DMCMNGTHR` field to set the threshold for the management data buffer that causes a move out of DMA coalescing operating mode. Any control data (packet generated by internal firmware) that is pending on MCTP over PCIe interrupts the coalescing. The manageability indications are ignored if `DMACR.EN_MNG_IND` is cleared.

**Note:** Any change to a DMA coalescing configuration should be done while the feature is disabled by setting `DMAR.DMAC_EN` to 0b.

## 5.5.2 DMA Coalescing Operating Mode

Enabling DMA coalescing operation by setting the `DMACR.DMAC_EN` bit to 1b, enables aligning bus master traffic and interrupts from all ports. Power saving is achieved since synchronizing PCIe accesses between ports increases the occurrence of idle intervals on the PCIe bus and also increases the duration of these idle intervals. The Power Management Unit (PMU) on a platform can use these idle intervals to reduce system power.

### 5.5.2.1 Conditions to Enter DMA Coalescing

The X550 enters DMA coalescing when all of the following conditions exist:

1. DMA coalescing is enabled (`DMACR.DMAC_EN` = 1b).
2. Internal receive buffers are empty.
3. There are no pending DMA operations.
4. There are no MCTP pending operations (if `DMACR.EN_MNG_IND` is set).
5. None of the conditions defined in [Section 5.5.2.2](#) to move out of DMA coalescing exist.

### 5.5.2.2 Conditions to Exit DMA Coalescing

When the X550 is in DMA coalescing operating mode, DMA coalescing mode is exited when one of the following events occurs:

1. Amount of data in the internal receive buffers passed the `DMCTH.DMACRXT` threshold.
2. An interrupt associated to a high priority vector defined by `EITR.HIGH_PRIORITY` was detected.
3. A received packet associated to a high priority traffic class defined by `DMACR.HIGH_PRIORITY` was detected.
4. DMA coalescing watchdog timer expires as a result of the following occurrences not being serviced for the duration defined in the `DMACWT` timer field:
  - a. An incoming Rx packet is received.
  - b. An MCTP transaction is pending (if `DMACR.EN_MNG_IND` is set).
  - c. An interrupt is pending.
  - d. An RSC flow was closed due to an ITR expiration.
5. DMA coalescing is disabled (`DMACR.DMAC_EN` = 0b).
6. PCIe link moves to an active L0 link power state (if the `DMACR.LX_COALESCING_INDICATION` bit is set to 1b) or any TLP transaction is detected on the PCIe interface (if the `DMACR.LX_COALESCING_INDICATION` bit is set to 0b).

**Notes:** Management indications are enabled through *DMACR.EN\_MNG\_IND* and the amount of data buffered in the management buffer exceeds *DMCMNGTH.DMCMNGTHR*.

Even when conditions for DMA coalescing do not exist, the X550 continues to be in low power PCIe link state (L0s or L1) if there is no requirement for PCIe access.

### 5.5.3 DMA Coalescing Recommended Settings

These are the recommended DMA Coalescing settings for the X550:

1. DMA Coalescing Receive Threshold per traffic class (*DMCTH.DMACRXT[TC]*) =  $\text{MAX}\{(\text{RPB\_Size}[TC] - 70\mu\text{s of Rx data}), \text{MFS}\}$

**Note:** The receive threshold must be set so that its distance from the Effective Rx Packet Buffer size ([Section 7.1.3.6.5](#)) allows buffering all Rx traffic that could be received at full blown during 70us, which corresponds to the worst case observed exit time from L1/L0s to L0. It means that the threshold setting depends on the link speed. A minimum of MFS (Maximum Frame Size) must be set for the DMA Coalescing threshold.

2. DMA Coalescing Watchdog Timer (*DMACR.DMACWT*) must be set to get a worst case packet delay of ~ 20ms.
  - a. If  $\text{TTLX} \geq \text{Max ITR delay over all Qs}$ :  $\text{DMACWT} = 0x262 \sim 20\text{ms}$ . Flush entire RPB to host before re-entering into DMA coalescing state. The longest time a packet can wait in packet buffer is *DMACWT*.
  - b. If  $\text{TTLX} < \text{Max ITR delay over all Qs}$ :  $\text{DMACWT} = (20\text{ms} - \text{Max ITR delay}) / 2$ . The device re-enters the DMA coalescing state as soon as the first packet which is waiting in packet buffer is served. Then, when the ITR timer for the second packet expires, the device starts the *DMACWT* timer (again). It comes out that in this case, the longest time a packet can wait in packet buffer is  $\text{ITR delay} + 2 \times \text{DMACWT}$ .
3. Time to LX request (*DMCTLX.TTLX*) =  $0x20 \sim 40\mu\text{s}$ , so that it is smaller than worst case L1/L0s max exit time (70us), taking advantage of the fact coalescing occurs in L0 too.
4. *DMACR.Lx\_Coalescing\_Indication* = 0b, i.e. coalescing occurs when in L0.
5. DMA Coalescing Management Threshold (*DMCMNGTH.DMCMNGTHR*) = 0x100 (Equivalent to 4 KB)

## 5.6 LTR

The X550 generates PCIe LTR messages to report service latency requirements for memory reads and writes to the root complex for system power management.

The X550 reports either latency tolerance or no latency tolerance requirements as a function of link, LAN port and function status. The reported latency tolerance value is set to optimize platform power consumption without incurring packet loss due to receive buffer overflow.

### 5.6.1 LTR Algorithm

The X550 sends LTR messages according to the following algorithm when the capability is enabled in the LTR capability structure of Function 0 located in the PCIe configuration space:

1. When links on all ports are disconnected, or all LAN ports are disabled, the software device driver instructs the X550 to send an LTR PCIe message with LTR requirement bits cleared, to indicate that no latency tolerance requirements exist.
2. If the X550 reported following PCIe link-up latency tolerance requirements with any requirement bit set in the PCIe LTR message and all enabled functions were placed in D3 low power state via the *PMCSR* register, the X550 sends a new LTR message with all the requirement bits clear.
3. If the X550 reported following PCIe link-up latency tolerance requirements with any requirement bit set, and the *LTR Mechanism Enable* bit in the PCIe configuration space is cleared, the software device driver instructs the X550 to send an LTR PCIe message with all the requirement bits clear.
4. The X550 holds the LTR value to send defined in LTR Control (*LTRC*) controlled and configured by the software device driver. The X550 sends a new LTR message with the minimum latency tolerance requirement value upon an explicit request from the software device driver (issued by setting *LTRC.LTR\_SEND* bit). The following event can cause a the X550 software device driver to change its latency tolerance requirement:
  - a. Link speed changed
  - b. Link was disconnected

The X550 conglomerates latency requirements from the different functions and sends a single LTR message in the following manner:

- The acceptable latency values for the message sent upstream by the X550 must reflect the lowest latency tolerance values associated with any function.
  - It is permitted that the snooped and non-snooped values reported in the conglomerated message are associated with different functions.
  - If none of the functions have a latency requirement for a certain type of traffic (snoop/non-snoop), the message sent by the X550 does not have the *Requirement* bit corresponding to that type of traffic set.
  - The Scale parameter should be set to zero by the software device driver if minimal latency is required for a specific type of traffic (Latency = 0 and Requirement is set).

## 5.6.2 LTR Initialization Flow

- BIOS/OS configures the maximum snoop/non-snoop platform latency in the PCIe (function 0) configuration LTR capability registers.
- As part of software device driver initialization, the software device driver:
  - Reads the LTR capability to get the worst case latency tolerance requirement for the platform that the X550 is connected to.
  - Auto negotiates extended LPI exit latencies.
  - The software device driver configures receive buffer watermarks for DMAC as aggressively as possible for the active target latency tolerance value (pre defined value).
  - The software device driver configures the content of the LTR snoop/non-snoop requirements to LTRC.
- The software device driver initiates sending a LTR message from the X550 by setting LTRC.Send.
- When a software device driver unloads, it should clear its latency tolerance requirements in the LTRC register and set the LTRC.LTR\_SEND bit, this could cause a new LTR message as defined in [Section 5.6.1](#).

## 5.7 Thermal Management

### 5.7.1 General

The X550's thermal management solution includes an on-die diode and an on-die thermal sensor used to:

- Monitor the die temperature (junction temperature) by an external device. Refer to [Section 12.5](#) for more details.
- Indicate junction temperature as well as being programmed to indicate that temperature thresholds (such as trip points) are reached.
- The thermal sensor indications can be monitored by:
  - The MC (see [Section 5.7.2](#))
  - Autonomously by the X550 in NVM-based mode (see [Section 5.7.3](#)).
  - By host software driver in NVM-based mode (see [Section 5.7.3.1](#)).

Thermal sensor registers are generally accessible only from MDIO of PHY 0.

**Note:** Host software might read these registers but must not change their programming. PHY registers remain accessible even after the PHY has been shut down by a thermal sensor event.

## 5.7.2 MC-Based Mode

The thermal sensor behavior relative to the thresholds/actions configured by MC is referred as the TS MC-based mode. It can be used by the MC to control an active heat sink or the fan operation if present on the board.

This mode can work together with the NVM mode, where the NVM mode is used by the software device driver, and this mode is used by the MC. Each mode uses different thresholds in the PHY.

The MC-based mode is configured via the Set Thermal Sensor Commands. Refer to [Section 11.5.11.1.9](#) (Legacy SMBus mode) and [Section 11.6.3.19](#) (NC-SI mode).

Thermal sensor event notifications can be issued:

- Via an AEN over NC-SI (see [Section 11.6.3.20.1](#))
- Via an SMBus alert (see [Section 11.5.6](#)).
- Via SDP1 output pin of LAN port 1 indication.

## 5.7.3 NVM-Based Mode

The thermal sensor behavior relative to the threshold configured via NVM is referred as the TS NVM-based mode. It is mainly useful for non-managed environments or when the MC does not support the thermal sensor commands. However, this mode can also be enabled in parallel to the TS MC-based mode, as a back up mode relying on a catastrophic threshold, which must be set beyond the thresholds configured by the MC to avoid any interference between the two defined modes (NVM based and MC based).

It is configured as follows:

- TS NVM-based mode is enabled via setting the *TS NVM-based Mode Enable* bit to 1b in the *Common Firmware Parameters* word ([Section 6.5.2.2](#)).
- Program the PHY NVM section as follows:
  - The thermal threshold should be set to 107 °C, by the PHY provisioning register 1E.C421 ([Section 10.6.11](#)) and 1E.C423 ([Section 10.6.13](#)) both set to 0x6B00.
  - Enable the high temperature failure alarm to assert the PHY Global Interrupt, via PHY provisioning register 1E.D400 bits E:B set to 1000b.
- Optionally, if on-board thermal alerts are required, set the SDP1 pin of LAN port 0 as an output pin that asserts on the thermal sensor event, via the *SDP1\_IODIR* bit (bit 9) set to 1b, the *SDP1\_NATIVE* bit (bit 17) set to 0b, and the *SDP1\_FUNCTION* bit (bit 25) set to 1b in the *SDP Control* word (Offset 0x20).
- Recovering from a thermal sensor PHY power down event in this mode requires a device power cycle.
- The host can check whether the TS NVM-based mode is enabled or not by reading bit 0 in FWSM register.

### 5.7.3.1 Thermal Sensor (TS) Monitoring by Host Software

When operating in NVM mode, thermal events can be monitored by the host device driver. The thermal sensor is configured by the NVM and should not be changed by host software. The junction temperature can be read from the Global Thermal Status 1: Address 1E.C820 register ([Section 10.6.29](#)).

**Note:** A guard band of  $\pm 3$  °C should be taken over thermal sensor temperature indication.

TS event notifications can be issued via:

- An interrupt to the host (via EICR.TS bit 23).
- SDP1 output pin of LAN port 0 indication.

**Note:** TS events are enabled by default and might be spurious. Host software should react TS events only if TS NVM-based mode is enabled ([Section 5.7.3](#)).

**Note:** To get an indication through SDP1, the NVM setting of SDP1 should be configured as described in [Section 5.7.3](#).

### 5.7.4 Thermal Sensor Control

The temperature sensor can be manually controlled by the host device driver through the MDIO, by setting the *Temperature Sense Override* bit to 1b.

Once the temperature sensor has performed the read, it asserts the *Temperature Ready* bit to 0b (see Global Thermal Status 2: Address 1E.C821 — [Section 10.6.30](#)). The temperature data can then be read from the Temperature [F:0] bits (see Common Thermal Status 1: Address 1E.2C820 — [Section 10.6.29](#)).

**Note:** Take in account that the *Temperature Sense Ready* bit toggles a number of times according to the number of samples configured in *Temperature Sense Sample Configuration* field (1E.2825) and to the wait time between samples configured in *Temperature Sense Wait Configuration* field (1E.2824).

### 5.7.5 Thermal Sensor Characteristics

**Table 5-6. Thermal Sensor Characteristics**

| Parameter       | Min              | Max    | Comment                                                   |
|-----------------|------------------|--------|-----------------------------------------------------------|
| Range           | 0 °C             | 125 °C | Temperature is reported as 16-bit unsigned decimal value. |
| Resolution      | 1/256 °C per LSB |        | For the least significant bit.                            |
| Accuracy        | +/- 3 °C         |        |                                                           |
| Conversion time | 11 ms            |        |                                                           |

## 6.0 Non-Volatile Memory Map

---

### 6.1 NVM Organization

The X550 NVM contains the following six high-level modules:

- **Legacy EEPROM Modules** — These modules are mapped over one of the first two 16 KB sections of the Flash device, and cannot be extended beyond them. It is composed of all the NVM modules used by MAC hardware or by manageability firmware, not including the manageability and PHY firmware code images. The sections included in this block are:
  - **NVM Pointers and Generic Words** — This section (described in [Section 6.1](#)) start is at the beginning of the valid section. It contains basic device information, pointers to other NVM modules, and several software configurations.
  - **PCI Analog Module** — This module is pointed by NVM word 0x2, and contains settings for the PCI PHY block. It is loaded only at Power On Reset.
  - **LCB Module** — This module is pointed by NVM word 0x3, and contains settings for the PCI Link Layer block. It is loaded at each PCI reset.
  - **PCIe Modules** — These modules (described in [Section 6.4.5](#) and [Section 6.4.6](#)) contain the parameters required to configure the PCIe configuration space. The pointers to these modules are located at NVM words 0x6 (Generic), 0x7 (Port 0), and 0x8 (Port 1).
  - **LAN Core Modules** — These two modules (described in [Section 6.4.7](#)) contain parameters required to configure the LAN port. These include the MAC Address, LED, and SDP configuration. The pointers to these modules are located at NVM words 0x9 (Port 0) and 0xA (Port 1). In addition, each LAN port has a module that enables loading specific CSR values after reset. The pointers to these modules are located at NVM words 0xD (Port 0) and 0xE (Port 1). These modules are loaded following a software or hardware reset.
  - **Firmware Parameters Module** — Pointed by Firmware Module Pointer located at NVM word 0x0F. The Firmware Extension Module starts with a list of firmware sub-modules pointers, as listed in [Table 6-6](#).
  - **Boot Configuration** — This module is pointed by NVM word 0x17, and contains the configuration parameters used by the PXE, iSCSI and FCoE boot code.
  - **VPD** — This module is pointed by NVM word 0x2F, and contains the VPD module exposed via the VPD PCIe capability as described in [Section 6.3.5](#).
- **Firmware Image** — This module contains the main code of the firmware loaded to the internal RAM. This image must fit within 512 KB and start at a 4 KB boundary. This module is authenticated upon update. See [Section 6.5.7](#) for details.

- **PCIe Expansion/Option ROM** — This module includes the PXE Driver (61 KB), iSCSI Boot Image (116 KB), FCoE Boot Image (80 KB), UEFI Network Driver (37 KB for x64, 67 KB for IA64), and can also include a CLP module (60 KB). It must fit within 512 KB and start at a 4 KB boundary. It is pointed by the *PCIe Expansion/Option ROM Pointer* located at the NVM word 0x05.
- **PHY Image** — This module includes the PHY micro controller Boot Vector section, two PHY registers provisional segments (one per port), and a PHY micro controller code/data segment. The PHY registers provisional segments are used to change the defaults of PHY registers. It must fit within 512 KB and start at a 4 KB boundary. The *PHY Image Pointer* is located at NVM word 0x04.
- **FCoE Scratch Pad** — A scratch pad used for FCoE software usage. The location of this area is described in the module pointed by word 0x39. The minimal allocated size is 8 KB, but can be larger if there is additional free area available in the NVM. The scratch pad is open to software read or write. Software device driver is responsible for the maintenance of this area.
- **Free Space Provisioning Segment** — The NVM structure includes a space utilized to update the PXE code, Firmware Image, and PHY Image modules via a double image policy. This space is referred as the Free Space Provisioning module or segment. It must be large enough to contain the largest of these three high-level modules, which means at least 512 KB in a 4 MB flash and 500 KB in a 2 MB flash. It is pointed by the *Free Space Provisioning Segment Pointer* located at NVM word 0x40. See [Section 3.4.8.1](#) for the usage model of this Flash area.

**Note:** Flash device size can be read from NVM Control Word 1 (see [Section 6.4.2.1](#)).

[Figure 6-1](#) shows a general NVM structure and not a required order.

Figure 6-1. NVM Structure

## 6.1.1 Protected Areas

The following areas are protected from host writes:

- The Firmware Code Area
- The PHY code Area
- The PCI configuration areas (PHY, Link)
- The pointers to the different modules.
- The mini loader
- NVM Control Words 1/2/4

The list of words and modules that are read-only to the software is listed in [Table 6-1](#).

The Firmware, PHY code areas, and Option ROM can be updated using the flow described in [Section 3.4.8.1](#).

Read/Write words can be updated using the flow described in [Section 3.4.7.6](#) and [Section 3.4.2.1](#).

## 6.2 NVM Header

**Note:** Intel configures the reserved NVM fields, and they are not intended to be changed beyond the default image provided by Intel.

Table 6-1 lists the fixed part of the Legacy EEPROM Modules used by the X550. This table lists common modules for the NVM including: hardware pointers, software and firmware. Blocks pointed in this section are detailed in the following sections. All addresses in this table are absolute in word units.

Pointers may be in word units or in 4 KB units. If bit 15 of the pointer is set, bits [14:0] point to a 4 KB sector, and the word address is {pointer[14:0], 000,0000,0000b}. If bit 15 is cleared, the word address is pointer[14:0].

**Table 6-1. Legacy EEPROM Modules Description**

| 0x50         | FW      | RO Updates Version - This field is copied by firmware from the RO <i>Updates Version</i> field present in the trailer of the firmware secured module. Refer to <a href="#">Section 6.5.7.2</a> . | FW           | RO Word                               |      |          |

1. Updated via RO words mechanism.

2. Updated via the secured module update flow ([Section 3.4.8.1](#)).

3. VPD area is updated via the VPD PCIe capability or via Shadow RAM Update host I/F command if *VPD Write Enable* bit in *NVM Control Word 1* is set.

All pointers refer to word addresses, except pointers to PCIe Expansion/Option ROM (0x5), PHY Image (0x4), Firmware Code (0x3A) and Free Space Provisioning Segment (0x41) which are expressed in 4 KB sector units.

## 6.3 Software Sections

This section describes both words in the NVM header and additional software sections pointed from the header.

### 6.3.1 Software Compatibility Module — Word Address 0x10-0x14

Five words in the NVM image are reserved for compatibility information. New bits within these fields are defined as the need arises for determining software compatibility between various hardware revisions.

**Note:** Unused words are filled with the default value 0xFFFF.

#### 6.3.1.1 Software Compatibility Word 1 - Device Usage — Word Address 0x10

This word is for platform/NIC/LOM specific usage.

| Bits  | Name       | Default | Description                                                                                                                                                                                                                                                 |

| 11    | LOM        | 0b      | Indicates whether the NVM attached to LAN silicon contains dedicated module for option ROM. Used by option ROM update applications.<br>0b = NIC (Attached flash contains module for option ROM).<br>1b = LOM (Attached flash has no module for option ROM). |
| 15:12 | Reserved   | 0x0     | Reserved.                                                                                                                                                                                                                                                   |

#### 6.3.1.2 Software Compatibility Word 2-5 — Reserved

## 6.3.2 PBA Number Module — Word Address 0x15-0x16

The nine-digit Printed Board Assembly (PBA) number used for Intel manufactured Network Interface Cards (NICs) is stored in the NVM.

**Note:** Through the course of hardware ECOs, the suffix field is increased. The purpose of this information is to enable customer support (or any user) to identify the revision level of a product.

Network driver software should not rely on this field to identify the product or its capabilities.

Current PBA numbers have exceeded the length that can be stored as hex values in these two words. For these PBA numbers, the high word is a flag (0xFAFA) indicating that the PBA is stored in a separate PBA block, and the low word is a pointer to a PBA block.

| PBA Number | Word 0x15 | Word 0x16            |
|------------|-----------|----------------------|
| G23456-003 | FAFA      | Pointer to PBA Block |

The PBA block is pointed to by word 0x16.

| Word Offset | Description                                     | Reserved |
|-------------|-------------------------------------------------|----------|
| 0x0         | Length in words of the PBA block (default 0x6). |          |
| 0x1... 0x5  | PBA number stored in hexadecimal ASCII values.  |          |

The PBA block contains the complete PBA number, including the dash and the first digit of the 3-digit suffix. For example:

| PBA Number | Byte Offset |    |    |    |    |    |    |    |    |    |    |    |
|------------|-------------|----|----|----|----|----|----|----|----|----|----|----|
|            | 0           | 1  | 2  | 3  | 4  | 5  | 6  | 7  | 8  | 9  | 10 | 11 |
| G23456-003 | 06          | 00 | 47 | 32 | 33 | 34 | 35 | 36 | 2D | 30 | 30 | 33 |

Older PBA numbers (starting with A,B,C,D,E) are stored directly in words 0x15 and 0x16. The dash itself is not stored nor is the first digit of the 3-digit suffix, as it is always 0b for relevant products.

| PBA Number | Byte 1 | Byte 2 | Byte 3 | Byte 4 |
|------------|--------|--------|--------|--------|
| 123456-003 | 12     | 34     | 56     | 03     |

**Note:** The PBA module (a length of 12 bytes) must be mapped in the first valid 16 KB sector of the Flash.

### 6.3.3 Boot Configuration Block — Word Address 0x17

The Boot Configuration module is located using the Word pointer (*Boot Configuration Address* field in word 0x17). The block length is embedded in the Boot module.

| Configuration Item          | Offset (Bytes) | Size (Bytes) | Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Boot LUN                                                              | 0x325:0x324    | 2            | Target LUN.                                                             |
| VLAN ID                                                               | 0x327:0x326    | 2            | VLAN ID for the Port. Default is 1.                                     |
| Target Boot Order                                                     | 0x328          | 1            | Target Boot Order.<br>Valid range is 0-4, with 0 meaning no boot order. |
| Reserved                                                              | 0x32B:0x329    | 3            | Reserved for future use. Should be set to zero.                         |
| Reserved                                                              | 0x383:0x32C    | 88           | Reserved for future use. Should be set to zero.                         |
| <b>Port 1 Configuration (Port 0 Configuration + FCoE Target 0..3)</b> |                |              |                                                                         |
| Same configuration as port 0. Add to each offset 0x25C.               |                |              |                                                                         |

## 6.3.4 Software Reserved — Words 0x18-0x2E

This area is reserved for software. Specific usage reserved for platform/NIC/LOM.

**Note:** Unused words are filled with the default value 0xFFFF.

### 6.3.4.1 NVM Dev Starter Version — Word Address 0x18

This field identifies the Dev Starter image from which the current image is derived.

| Bits  | Name  | Default | Description                                                                                                                                                 |
|-------|-------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0   | ID    |         | NVM Dev Starter minor version (Hexadecimal value represent the decimal minor version. For example a value of 0x58 represent a decimal minor version of 58). |
| 11:8  | Zero  |         | Represents the decimal point.                                                                                                                               |
| 15:12 | Major |         | NVM Dev Starter major version (0-9).                                                                                                                        |

### 6.3.4.2 PHY Firmware Image Revision — Word Address 0x19

| Bits  | Name                  | Default | Description                 |
|-------|-----------------------|---------|-----------------------------|
| 3:0   | Point Release Version |         | PHY firmware image ID.      |
| 11:4  | Minor                 |         | PHY firmware minor version. |
| 15:12 | Major                 |         | PHY firmware major version. |

### 6.3.4.3 Software 9 - PXE VLAN Configuration Block — Word Address 0x20

Word 0x20 points to the PXE VLAN Configuration Block.

**Note:** Default value 0xFFFF means this word is not used.

| Bits | Name            | Default | Description                                                                                     |
|------|-----------------|---------|-------------------------------------------------------------------------------------------------|
| 15:0 | PXE VLAN Config | 0xFFFF  | Pointer to the PXE VLAN configuration block.<br>0x0000 and 0xFFFF indicates an invalid pointer. |

#### 6.3.4.3.1 PXE VLAN Configuration Block

Devices which support PXE VLAN configuration will define the following PXE VLAN Configuration block. This block is pointed to by the PXE VLAN Config word - 0x20.

| Byte Offset | Size (in Bytes) | Default | Name                 | Description                                                                                                                                                                    |
|-------------|-----------------|---------|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0           | 2               | 'V','L' | VLAN Block Signature | Signature which indicates that the block is correctly allocated.                                                                                                               |
| 2           | 1               | 1       | Structure Version    | Version of this structure. Should be set to 1.                                                                                                                                 |
| 3           | 1               | 0xA     | Block Size           | Total byte size of the configuration block.                                                                                                                                    |
| 4           | 2               | 0x0     | Port 0 VLAN Tag      | VLAN tag and priority values for first port of the controller (for details, see bits definition in <a href="#">Table 6-2</a> ).<br>Value 0 means no VLAN configured for port.  |
| 6           | 2               | 0x0     | Port 1 VLAN Tag      | VLAN tag and priority values for second port of the controller (for details, see bits definition in <a href="#">Table 6-2</a> ).<br>Value 0 means no VLAN configured for port. |

[Table 6-2](#) defines the VLAN tag and priority values for the individual ports listed in the PXE VLAN Configuration block ([Section 6.3.4.3](#)):

**Table 6-2. VLAN Tag and Priority Values**

| Bits  | Name     | Description                                       |
|-------|----------|---------------------------------------------------|
| 11:0  | VLAN ID  | VLAN ID for the port. Valid values are 1–4095.    |
| 12    | Reserved | Reserved. Always 0x0.                             |
| 15:13 | Priority | VLAN Priority for the port. Valid values are 0–7. |

### 6.3.4.4 Software Reserved Word 16 - Alternate SAN MAC Address — Word Address 0x27

Word 0x27 points to the Alternate SAN MAC Address block used by FCoE.

**Note:** Default value 0xFFFF means this word is not used.

| Bits | Name                              | Default | Description                                                                                                                 |
|------|-----------------------------------|---------|-----------------------------------------------------------------------------------------------------------------------------|
| 15:0 | Alternate SAN MAC Address Pointer | 0xFFFF  | Pointer to the Alternate SAN MAC Address block.<br>Used by both software and firmware. 0xFFFF indicates an invalid pointer. |

#### 6.3.4.4.1 Alternate SAN MAC Address Block

Word 0x27 points to the Alternate SAN MAC Address Block used to store the alternate SAN MAC Addresses and alternate WWN prefixes. Offsets to the SAN MAC Addresses are defined as follows:

| Word Offset | Default | Description                              |
|-------------|---------|------------------------------------------|
| 0x0         | 0x0003  | Capabilities                             |
| 0x1 – 0x3   | 0xFFFF  | Alternate SAN MAC Address 1 (function 0) |
| 0x4 – 0x6   | 0xFFFF  | Alternate SAN MAC Address 2 (function1)  |
| 0x7         | 0xFFFF  | Alternate WWNN prefix                    |
| 0x8         | 0xFFFF  | Alternate WWPNN prefix                   |

#### 6.3.4.4.2 Capabilities – Offset 0x0

The capabilities block indicates which words are supported. It is primarily for future expansion, if necessary.

| Bits | Name                      | Default | Description                                                                                                                     |
|------|---------------------------|---------|---------------------------------------------------------------------------------------------------------------------------------|
| 0    | Alternate SAN MAC Address | 1b      | Alternate SAN MAC Address words (0x1...0x6) are available, and can be written to.                                               |
| 1    | Alternate WWN Base        | 1b      | Alternate WWN base addresses (0x7 and 0x8) are allocated in the alternate SAN MAC Address block, and can be read or written to. |
| 15:2 | Reserved                  | 0x0     | Reserved.                                                                                                                       |

#### 6.3.4.5 Software Reserved Word 17 - Permanent SAN MAC Address – Word Address 0x28

Word 0x28 points to the Active SAN MAC Address block used for FCoE (SPMA and FPMA) and DCB.

| Bits | Name                    | Default | Description                                                                          |
|------|-------------------------|---------|--------------------------------------------------------------------------------------|
| 15:0 | SAN MAC Address Pointer | 0xFFFF  | Pointer to the Active SAN MAC Address block.<br>0xFFFF indicates an invalid pointer. |

#### 6.3.4.5.1 Active SAN MAC Address Block

Offsets to the SAN MAC Addresses are defined in the following table:

| Word Offset | Description                    |
|-------------|--------------------------------|
| 0x0 – 0x2   | SAN MAC Address 1 (function 0) |
| 0x3 – 0x5   | SAN MAC Address 2 (function 1) |

### 6.3.4.6 Software Reserved Word 18 - DS\_Version — Word Address 0x29

Word 0x29 is for the map version.

| Bits  | Name  | Default | Description                                                                                                                                         |
|-------|-------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0   | ID    |         | NVM map minor version (Hexadecimal value represent the decimal minor version. For example a value of 0x58 represent a decimal minor version of 58). |
| 11:8  | Zero  |         | Represents the decimal point.                                                                                                                       |
| 15:12 | Major |         | NVM map major version (0-9).                                                                                                                        |

### 6.3.4.7 Software Reserved Word 19 - OEM Image Version — Word Address 0x2A

Optional field that enables an OEM to write a version and OEM identifies in the NVM image. Used only for OEM NVM images.

| Bits  | Name  | Default | Description                                                                                                                                           |
|-------|-------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0   | ID    |         | NVM Image minor version (Hexadecimal value represent the decimal minor version. For example a value of 0x58 represent a decimal minor version of 58). |
| 11:8  | Zero  |         | Represents the decimal point.                                                                                                                         |
| 15:12 | Major |         | NVM Image major version (0-9).                                                                                                                        |

### 6.3.4.8 Software Reserved Word 21 — Word Address 0x2C

This word is for platform/NIC/LOM specific capabilities.

| Bits | Name                | Default | Description                                                                                                                                                                                                                 |
|------|---------------------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1:0  | Reserved            | 11b     | Reserved.                                                                                                                                                                                                                   |
| 3:2  | Wake On LAN Support | 11b     | This bit indicates to software if the X550 supports Wake on LAN.<br>00b = Reserved (not supported).<br>01b = WoL supported on both ports.<br>10b = WoL supported on port A only.<br>11b = WoL not supported on either port. |
| 15:7 | Reserved            | 0xFFFF  | Reserved                                                                                                                                                                                                                    |

### 6.3.5 VPD Module Pointer — Word Address 0x2F

The Vital Product Data (VPD) module is located using the Word pointer VPD Pointer field in word 0x2F. The block length is embedded in the VPD module. The VPD section size is up to 1 KB, and is initialized to 0x0 or 0xFFFF. Customers write their own data in this module. During runtime, this module is accessible through the VPD capability in the PCI configuration space.

## 6.3.6 PXE Configuration Words — Word Address 0x30-0x36

Words 0x30 through 0x36 are reserved for configuration and version values used by pre-boot software (PXE/iSCSI boot/ FCoE boot/ UEFI codes).

| Word Address | Description                                            | Page | Reserved |

### 6.3.6.1 PXE Setup Options PCI Function 0 — Word Address 0x30

The main setup options for Port 0 are stored in this word. These options are those that can be changed by the user using the Control-S setup menu.

### 6.3.6.2 PXE Configuration Customization Options PCI Function 0 — Word Address 0x31

Word 0x31 of the NVM contains settings that can be programmed by an OEM or network administrator to customize the operation of the software. These settings cannot be changed from within the Control-S setup menu. The lower byte contains settings that would typically be configured by a network administrator using an external utility; these settings generally control which setup menu options are changeable. The upper byte is generally settings that would be used by an OEM to control the operation of the agent in a LOM environment, although there is nothing in the agent to prevent their use on a NIC implementation. The default value for this word is 0x4000.

| Bits | Name | Default | Description                                                                                                                                                                                                                                                     |
|------|------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0    | DSM  | 0b      | Disable Setup Menu.<br>If this bit is set to 1b, the user is not allowed to invoke the setup menu by pressing Control-S. In this case, the NVM can only be changed via an external program.                                                                     |
| 1    | DTM  | 0b      | Disable Title Message.<br>If this bit is set to 1b, the title message displaying the version of the Boot Agent is suppressed; the Control-S message is also suppressed. This is for OEMs who do not wish the boot agent to display any messages at system boot. |

| Bits  | Name     | Default | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

### 6.3.6.3 PXE Version — Word Address 0x32

Word 0x32 of the NVM is used to store the version of the PXE that is stored in the Flash image. When the PXE loads, it can check this value to determine if any first-time configuration needs to be performed. PXE then updates this word with its version. Some diagnostic tools also read this word to report the version of the PXE in the Flash.

| Bits  | Name | Default | Description        |
|-------|------|---------|--------------------|
| 7:0   | BLD  | 0x0     | PXE Build number.  |
| 11:8  | MIN  | 0x0     | PXE Minor version. |
| 15:12 | MAJ  | 0x0     | PXE Major version. |

#### 6.3.6.4 Flash Capabilities — Word Address 0x33

Word 0x33 of the NVM is used to enumerate the boot technologies that have been programmed into the Flash. This is updated by Flash configuration tools and is not updated by option ROMs.

| Bits  | Name     | Default | Description                                                                                                                   |
|-------|----------|---------|-------------------------------------------------------------------------------------------------------------------------------|
| 0     | BC       |         | PXE Base Code is present if set to 1b.                                                                                        |
| 1     | UNDI     |         | PXE UNDI driver is present if set to 1b.                                                                                      |
| 2     | RPL      |         | RPL module is present if set to 1b. Reserved bit for devices.                                                                 |
| 3     | EFI      |         | EFI UNDI driver is present if set to 1b.                                                                                      |
| 4     | ISCSI    |         | iSCSI boot code is present if set to 1b.                                                                                      |
| 5     | FCOE     |         | FCoE boot code is present if set to 1b.                                                                                       |
| 13:6  | Reserved | 0x0     | Reserved. Must be set to 0x0.                                                                                                 |
| 15:14 | SIG      |         | Signature.<br>Must be set to 01b to indicate that this word has been programmed by the agent or other configuration software. |

#### 6.3.6.5 PXE Setup Options PCI Function 1 — Word Address 0x34

This word is the same as word 0x30, but for PCIe function 1 of the device (refer to [Section 6.3.6.1](#)).

#### 6.3.6.6 PXE Configuration Customization Options PCI Function 1 — Word Address 0x35

This word is the same as word 0x31, but for PCIe function 1 of the device (refer to [Section 6.3.6.2](#)).

#### 6.3.6.7 iSCSI Option ROM Version — Word Address 0x36

Word 0x36 of the NVM is used to store the version of iSCSI Option ROM updated as the same format as PXE Version at Word 0x32 ([Section 6.3.6.3](#)). The value must be above 0x2000 and the value below (word 0x1FFF = 16 KB NVM size) is reserved. iSCSIUtil, FLAUtil, DMiX update iSCSI Option ROM version if the value is above 0x2000, 0x0000, or 0xFFFF. The value (0x0040 - 0x1FFF) should be kept and not be overwritten.

#### 6.3.7 Alternate Ethernet MAC Address Pointer — Word Address 0x37

The alternate MAC Address does not function if the pointer value is set to 0xFFFF.

Word offset for PCIe function 0 MAC Address is: value in word 0x37 + 0 - 3 words.

Word offset for PCIe function 1 MAC Address is: value in word 0x37 + 3 - Next 3 words.

This word is used as a pointer to an EEPROM block that contains the space for two MAC Addresses. The first three words of the EEPROM block are used to store the MAC Address for PCIe Function 0. The second three words of the EEPROM block is used to store the MAC Address for PCIe Function 1. Initial and default values in the EEPROM block should be set to 0xFFFF (for both addresses) indicating that no alternate MAC Address is present. See [Section 4.6.13](#) for more details.

**Note:** Word 0x37 must be set to 0xFFFF if alternate MAC Addresses are not used. Also, alternate MAC Addresses are ignored by hardware and require specific software support for activation.

| Word Offset | Description                                   | Reserved |
|-------------|-----------------------------------------------|----------|
| 0x0 – 0x2   | Alternate Ethernet MAC Address 1 (function 0) |          |
| 0x3 – 0x5   | Alternate Ethernet MAC Address 2 (function 1) |          |

### 6.3.8 FCoE Scratch Pad Pointer — Word Address 0x39

This word contains a pointer to a module describing the FCoE scratch pad. The content of the module is described below:

## 6.4 Hardware Sections

| Word Offset | Description                                                                                     | Reserved |
|-------------|-------------------------------------------------------------------------------------------------|----------|
| 0x0         | Address of scratch pad (in 4Kbytes resolution). Bit[15] should be set to indicate a 4K pointer. |          |
| 0x1         | Size of scratch pad (in 4Kbytes resolution).                                                    |          |

This module contains address control words and hardware pointers indicated as hardware in [Table 6-1](#). The process of loading this module (or any of its sub-modules) into the device is referred to as MAC auto-load process. These modules must be mapped in the first valid 16 KB section of the Flash.

### 6.4.1 Hardware Section — Auto-Load Sequence

The following table lists sections of auto-read following device reset events or specific commands from registers. Auto-read is performed from the internal Shadow RAM (or from internal memory for PHY module) and not from the NVM device, except following LAN\_PWR\_GOOD or Reset Pin events.

**Table 6-3. NVM Section Auto-Read**

|                                                    | LAN_PWR_GOOD or Reset Pin | PCIe Reset or PCIe Inband Reset | D3 to D0 Transit (per port) | FLR (per port) | SW Reset (per port) | Link Reset (per port) | FW Reset | Force TCO | PHY Image Re-Load Command <sup>1</sup> |
|----------------------------------------------------|---------------------------|---------------------------------|-----------------------------|----------------|---------------------|-----------------------|----------|-----------|----------------------------------------|
| PCIe Analog Configuration                          | X <sup>2</sup>            |                                 |                             |                |                     |                       |          |           |                                        |
| PCI Link Configuration (LCB)                       |                           | X                               |                             |                |                     |                       |          |           |                                        |
| PCIe General Configuration                         |                           | X                               |                             |                |                     |                       |          |           |                                        |
| PCIe Function 0/1 Config Space (for each function) |                           | X                               |                             |                |                     |                       |          |           |                                        |
| LAN Core and CSRs (for each LAN port)              | X                         | X                               | X                           | X              | X                   | X                     |          | X         |                                        |
| PHY Module (for each LAN port)                     | X                         |                                 |                             |                |                     |                       |          |           | X                                      |
| Manageability Firmware Module                      | X                         |                                 |                             |                |                     |                       | X        |           |                                        |

1. via MDIO (per port) PHY register bit 1E.C442.0

2. This is the unique module that requires power-up to be reloaded.

### 6.4.2 NVM Init Module

The Init section (NVM Control Word 1, 2, and 3) are read after LAN\_PWR\_GOOD reset and PCIe Reset.

### 6.4.2.1 NVM Control Word 1 — Word Address 0x00

| Bits  | Name                | Default | Description                                                                                                                                                                                                                                                                                                                                                                                   | Reserved |
|-------|---------------------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 4:0   | Reserved            | 0x0     | Reserved.                                                                                                                                                                                                                                                                                                                                                                                     |          |
| 5     | VPD Write Enable    | 1b      | VPD Write Enable.<br>0b = Any host attempt to modify the VPD area via the Flash Update host I/F command is completed with an error.<br>1b = The host can modify the entire VPD area via the Shadow RAM Write host I/F command ( <a href="#">Section 11.8.3.3.4</a> ).<br><b>Note:</b> RW-VPD area can be modified from the config space register set regardless of the setting of this field. |          |
| 7:6   | Signature           | 01b     | The <i>Signature</i> field indicates to the X550 that there is a valid NVM present. If the <i>Signature</i> field is not 01b, the other bits in this word are ignored, no further NVM read is performed, and the default values are used for the configuration space IDs.                                                                                                                     |          |
| 10:8  | NVM Size            | 101b    | These bits indicate the physical Flash size. Mapped to FLA.FL_SIZE (see field definition in the FLA register - <a href="#">Section 8.2.2.2.2</a> ).                                                                                                                                                                                                                                           |          |
| 13:11 | Reserved            | 001b    | Reserved.                                                                                                                                                                                                                                                                                                                                                                                     |          |
| 14    | NC-SI HW ARB Enable | 0b/1b   | NC-SI Hardware Arbitration Enable.<br>0b = NCSI_ARB_IN and NCSI_ARB_OUT pads are not used. NCSI_ARB_IN is pulled up internally to provide stable input.<br>1b = NCSI_ARB_IN and NCSI_ARB_OUT pads are used.                                                                                                                                                                                   |          |
| 15    | Reserved            | 0b      | Reserved.                                                                                                                                                                                                                                                                                                                                                                                     |          |

### 6.4.2.2 NVM Control Word 2 — Word Address 0x01

| Bits | Name                     | Default | Description                                                                                                                                                                                                                                                                                                                                                                                                       | Reserved |

| 5    | D10GMP Port 0       | 0b      | Disable 1 GbE in LPLU for LAN Port 0.<br>When set, LAN port 0 never advertises 1 GbE speed capability when in LPLU state (D3/Dr). If set, D10GMP bit must be set as well.                                                                                                                                          |          |
| 6    | D10GMP Port 0       | 0b      | Disable 10 GbE in LPLU for LAN Port 0.<br>When set, LAN port 0 never advertises 10 GbE speed capability when in LPLU state (D3/Dr).                                                                                                                                                                                |          |
| 7    | D10GMP Port 1       | 0b      | Disable 1 GbE in LPLU for LAN Port 1.<br>When set, LAN port 1 never advertises 1 GbE speed capability when in LPLU state (D3/Dr). If set, D10GMP bit must be set as well.                                                                                                                                          |          |

| Bits | Name          | Default | Description                                                                                                                         | Reserved |
|------|---------------|---------|-------------------------------------------------------------------------------------------------------------------------------------|----------|
| 8    | D10GMP Port 1 | 0b      | Disable 10 GbE in LPLU for LAN Port 1.<br>When set, LAN port 1 never advertises 10 GbE speed capability when in LPLU state (D3/Dr). |          |
| 15:9 | Reserved      | 0x0     | Reserved.                                                                                                                           |          |

1. In regular mode (port swap disabled) Wol of port 0 is mapped to GRC.APME of NC-SI channel 0, port 0.  
In regular mode (port swap disabled) Wol of port 1 is mapped to GRC.APME of NC-SI channel 1, port 1.  
In port swap mode Wol of port 0 is mapped to GRC.APME of NC-SI channel 1, port 0.  
In port swap mode Wol of port 1 is mapped to GRC.APME of NC-SI channel 0, port 1.

### 6.4.3 PCIe Analog Configuration Module

This section is loaded at power on reset only. This section contains the PHY default configurations for the X550's PCIe analog parts. Word 0x2 in the NVM is the pointer for this section.

The structure of this section is listed in the following table.

| Word Offset          | Description                           | Reserved |
|----------------------|---------------------------------------|----------|
| 0x0                  | Section Length (in words)             |          |
| 0x1 – Section Length | Raw Data of the PCIe Analog microcode |          |

#### 6.4.3.1 Section Length — Offset 0x00

The Section Length word contains the length of the section in words. Section length does not include the Section Length word itself. The maximum size for this section is 8K-1 words (16382 bytes).

### 6.4.4 PCIe Link Configuration Module

This section is loaded after each PCI reset. This section contains the Link (LCB) default configurations for the X550's PCIe digital parts. NVM Word 0x3 is the pointer for this section. The structure of this section is listed in the following table.

| Word Offset | Description               | Reserved |
|-------------|---------------------------|----------|
| 0x0         | Section Length (in words) |          |
| 0x1 – 0x2   | PCIe LCB Address 1        |          |
| 0x3 – 0x4   | PCIe LCB Data 1           |          |
| 0x5 – 0x6   | PCIe LCB Address 2        |          |
| 0x7 – 0x8   | PCIe LCB Data 2           |          |
| ...         | ...                       |          |

#### 6.4.4.1 Section Length — Offset 0x00

The Section Length word contains the length of the section in words. Section length does not include the Section Length word itself. The 2 LS bits must be zero. The maximum allowed value is 8K - 4 (8188).

#### 6.4.4.2 PCIe LCB Address — Offset 0x01-0x2, 0x05-0x6...

The two first words in a quad word set in the PCIe LCB section contains the register address in the LCB internal register space.

#### 6.4.4.3 PCIe LCB Data — Offset 0x03-0x04, 0x07-0x8...

The two last words in a quad word set in the PCIe LCB section contains the register data. After reading a pair of address words and data words, the register specified in the address words is loaded with the data from the data words.

### 6.4.5 PCIe General Configuration Module

This section is loaded after a PCIe Reset. It contains general configuration for the PCIe interface (not function specific) and is pointed to by word 0x06 in the NVM (full-byte address; must be word aligned).

This section contains initial values for a predefined list of CSRs as described below.

#### 6.4.5.1 CSR Data — Offset 0x0-0x23

Even words:

| Bits | Name         | Default | Description   | Reserved |
|------|--------------|---------|---------------|----------|
| 15:0 | CSR_Data_LSB | 0x0     | CSR Data LSB. |          |

Odd words:

| Bits | Name         | Default | Description   | Reserved |
|------|--------------|---------|---------------|----------|
| 15:0 | CSR_Data_MSB | 0x0     | CSR Data MSB. |          |

The following registers are read through this section:

| Offset <sup>1</sup> | CSR Name     | Default    | Description                        | Page                | Reserved |
|---------------------|--------------|------------|------------------------------------|---------------------|----------|
| 0x0 – 0x1           | PCI_CNF2     | 0x400040FC | MSI-x and cache line configuration | <a href="#">533</a> |          |
| 0x2 – 0x3           | PCI_LBARCTRL | 0x00001949 | PF BAR registers configuration     | <a href="#">528</a> |          |
| 0x4 – 0x5           | PCI_SERL     | N/A        | PCIe Serial Number Low             | <a href="#">532</a> |          |
| 0x6 – 0x7           | PCI_SERH     | N/A        | PCIe Serial Number High            | <a href="#">529</a> |          |
| 0x8 – 0x9           | PCI_CAPCTRL  | N/A        | VPD Enable                         | <a href="#">530</a> |          |

| Offset <sup>1</sup> | CSR Name                  | Default                       | Description                                                | Page | Reserved |
|---------------------|---------------------------|-------------------------------|------------------------------------------------------------|------|----------|
| 0x16 – 0x17         | PCI_VFSUP                 | 0x2                           | PF BAR registers configuration                             | 532  |          |
| 0x18 – 0x19         | Reserved                  | 0x00001800                    | Reserved                                                   |      |          |
| 0x1A – 0x1B         | PCI_LINKCAP               | 0x00000E80                    | PCIe Link Capabilities                                     | 531  |          |
| 0x1C – 0x1D         | PCI_PMSUP                 | 0x00007397                    | PCIe Power Management Support                              | 531  |          |
| 0x1E – 0x1F         | PCI_GLBL_CNF              | System dependent <sup>3</sup> | Wake# enable                                               | 532  |          |
| 0x20 – 0x21         | PCI_VENDORID <sup>4</sup> | 0x00008086                    | PCIe Vendor ID                                             | 528  |          |
| 0x22 – 0x23         | PCI_PCIERR                | 0x00003FCB                    | Defines the PCI errors to be reported to the device driver | 521  |          |

1. For each register, the first word contains the Least Significant Bytes and the second word describes the Most Significant Bytes.
2. This register is loaded only if the PCI\_CAPSUP.LOAD\_SUBSYS\_ID bit is set.
3. The WAKE\_PIN\_EN may be modified in different systems,. The other bits are set to the hardware default.
4. This register is loaded only if the PCI\_CAPSUP.LOAD\_DEV\_ID bit is set.

**Notes:** This module must be mapped in the first valid 16 KB sector of the Flash because of the Serial Number Ethernet MAC Address field which may be modified during normal operation.

## 6.4.6 PCIe Configuration Space 0/1 Modules

Word 0x7 points to the PCIe configuration space defaults of function 0, while word 0x8 points to function 1 defaults. Both sections are loaded after PCIe Reset. The structures of both functions are identical and contains initial values for a predefined list of CSRs as listed below.

### 6.4.6.1 CSR Data — Offset 0x0-0x7

Even words:

| Bits | Name         | Default | Description   | Reserved |
|------|--------------|---------|---------------|----------|
| 15:0 | CSR_Data_LSB | 0x0     | CSR Data LSB. |          |

Odd words:

| Bits | Name         | Default | Description   | Reserved |
|------|--------------|---------|---------------|----------|
| 15:0 | CSR_Data_MSB | 0x0     | CSR Data MSB. |          |

The following registers are read through this section:

| Offset    | CSR Name    | Default                                                | Description                          | Page | Reserved |
|-----------|-------------|--------------------------------------------------------|--------------------------------------|------|----------|
| 0x0 – 0x1 | PCI_PFDEVID | 0x15631563                                             | PCIe PF Device ID <sup>1</sup>       | 527  |          |
| 0x2 – 0x3 | PCI_CNF     | Function 0:<br>0x00000000<br>Function 1:<br>0x00000020 | PCIe PF Configuration space settings | 527  |          |
| 0x4 – 0x5 | PCI_VFDEVID | 0x15651565                                             | PCIe VF Device ID                    | 527  |          |
| 0x6 – 0x7 | PCI_CLASS   | 0x0                                                    | PCIe Storage Class                   | 528  |          |

1. This register is loaded only if the PCI\_CAPSUP.LOAD\_DEV\_ID bit is set.

## 6.4.7 LAN Core 0/1 Modules

Word 0x9 points to the core configuration defaults of LAN port 0 while word 0xA points to LAN port 1 defaults. The section of each function is loaded at the de-assertion of its core master reset: PCIe Reset, D3 to D0 transition, software reset and link reset. The structures of both functions are identical as listed in the following table.

| Offset | High Byte [15:8]            | Low Byte [7:0]              | Page |
|--------|-----------------------------|-----------------------------|------|
| 0x0    | Section Length              |                             | 226  |
| 0x1    | Ethernet MAC Address Byte 2 | Ethernet MAC Address Byte 1 | 227  |
| 0x2    | Ethernet MAC Address Byte 4 | Ethernet MAC Address Byte 3 | 227  |
| 0x3    | Ethernet MAC Address Byte 6 | Ethernet MAC Address Byte 5 | 227  |
| 0x4    | LED 1 configuration         | LED 0 Configuration         | 227  |
| 0x5    | LED 3 Configuration         | LED 2 Configuration         | 228  |
| 0x6    | SDP Control                 |                             | 228  |
| 0x7    | Filter Control              |                             | 229  |

### 6.4.7.1 Section Length — Offset 0x00

The Section Length word contains the length of the section in words. Section length does not include the Section Length word itself.

| Bits | Name           | Default | Description              | Reserved |
|------|----------------|---------|--------------------------|----------|
| 15:0 | Section Length | 0x7     | Section length in words. |          |

### 6.4.7.2 Ethernet MAC Address Registers

The Ethernet Individual Address (IA) is a 6-byte field that must be unique for each NIC and must also be unique for each copy of the NVM image. The first three bytes are vendor specific. For example, the IA is equal to [00 AA 00] or [00 A0 C9] for Intel products. The value of this field is loaded into the Receive Address register 0 (RAL0/RAH0).

For the purpose of this specification, the numbering convention is as follows:

| Vendor         | 1  | 2  | 3  | 4        | 5        | 6        |
|----------------|----|----|----|----------|----------|----------|
| Intel original | 00 | AA | 00 | Variable | Variable | Variable |
| Intel new      | 00 | A0 | C9 | Variable | Variable | Variable |

#### 6.4.7.2.1 Ethernet MAC Address Register1 — Offset 0x01

| Bits | Name           | Default | Description                 | Reserved |
|------|----------------|---------|-----------------------------|----------|
| 7:0  | Eth_Addr_Byte1 | 0x0     | Ethernet MAC Address Byte1. |          |
| 15:8 | Eth_Addr_Byte2 | 0x0     | Ethernet MAC Address Byte2. |          |

#### 6.4.7.2.2 Ethernet MAC Address Register2 — Offset 0x02

| Bits | Name           | Default | Description                 | Reserved |
|------|----------------|---------|-----------------------------|----------|
| 7:0  | Eth_Addr_Byte3 | 0x0     | Ethernet MAC Address Byte3. |          |
| 15:8 | Eth_Addr_Byte4 | 0x0     | Ethernet MAC Address Byte4. |          |

#### 6.4.7.2.3 Ethernet MAC Address Register3 — Offset 0x03

| Bits | Name           | Default | Description                 | Reserved |
|------|----------------|---------|-----------------------------|----------|
| 7:0  | Eth_Addr_Byte5 | 0x0     | Ethernet MAC Address Byte5. |          |
| 15:8 | Eth_Addr_Byte6 | 0x0     | Ethernet MAC Address Byte6. |          |

### 6.4.7.3 LED Configuration

The LEDCTL register ([Section 8.2.2.1.10](#)) defaults are loaded from two words as listed in the following tables.

#### 6.4.7.3.1 LED Control Lower Word — Offset 0x04

| Bits | Name    | Default | Description    | Reserved |
|------|---------|---------|----------------|----------|
| 7:0  | LEDCTL0 | 0x00    | LED 0 Control. |          |
| 15:8 | LEDCTL1 | 0x81    | LED 1 Control. |          |

### 6.4.7.3.2 LED Control Upper Word — Offset 0x05

| Bits | Name    | Default | Description    | Reserved |
|------|---------|---------|----------------|----------|
| 7:0  | LEDCTL2 | 0xC4    | LED 2 Control. |          |
| 15:8 | LEDCTL3 | 0x05    | LED 3 Control. |          |

**Note:** The content of the NVM words is similar to the register content.

### 6.4.7.4 SDP Control — Offset 0x06

| Bits | Name           | Default | Description                                                                                                                                                                                                                                               | Reserved |
|------|----------------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 0    | SDPVAL[0]      | 0b      | SDP0 Pin.<br>Initial Output Value is mapped to ESDP.SDP0_DATA loaded at power-up.                                                                                                                                                                         |          |

### 6.4.7.5 Filter Control — Offset 0x07

| Bits | Name     | Default | Description | Reserved |
|------|----------|---------|-------------|----------|
| 15:0 | Reserved | 0x0001  | Reserved.   |          |

## 6.4.8 CSR 0/1 Auto Configuration Modules

Word 0xD points to the CSR auto configuration of function 0 while word 0xE points to function 1. Both sections are loaded at the de-assertion of their core master reset.

The structures of both sections are identical, and are listed in the following table.

| Offset  | High Byte [15:8]     | Low Byte [7:0] | Page |
|---------|----------------------|----------------|------|
| 0x0     | Section Length = 3*n |                | 229  |
| 0x1     | CSR Address          |                | 230  |
| 0x2     | Data LSB             |                | 230  |
| 0x3     | Data MSB             |                | 230  |
|         | ...                  |                |      |
| 3*n - 2 | CSR Address          |                | 230  |
| 3*n - 1 | Data LSB             |                | 230  |
| 3*n     | Data MSB             |                | 230  |

**Note:** The X550 blocks any write to the analog configuration registers through these sections.

### 6.4.8.1 Section Length — Offset 0x0

The Section Length word contains the length of the section in words. Section length does not include the Section Length word itself.

| Bits | Name           | Default | Description              | Reserved |
|------|----------------|---------|--------------------------|----------|
| 15:0 | Section_length | 0x0     | Section length in words. |          |

### 6.4.8.2 CSR Address — Offset 0x1, 0x4, 0x7...

| Bits | Name     | Default | Description                                                                                                                                     | Reserved |
|------|----------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 15:0 | CSR_ADDR | 0x0     | CSR Address bits [17:2], assuming bits [1:0] are always cleared. This allows coverage of full CSR address range [17:0] (Dword aligned address). |          |

### 6.4.8.3 CSR Data LSB — Offset 0x2, 0x5, 0x8...

| Bits | Name         | Default | Description   | Reserved |
|------|--------------|---------|---------------|----------|
| 15:0 | CSR_Data_LSB | 0x0     | CSR Data LSB. |          |

### 6.4.8.4 CSR Data MSB — Offset 0x3, 0x6, 0x9...

| Bits | Name         | Default | Description   | Reserved |
|------|--------------|---------|---------------|----------|
| 15:0 | CSR_Data_MSB | 0x0     | CSR Data MSB. |          |

**Table 6-4. Auto-Loaded CSRs**

| Offset    | CSR Name | Address    | Default    | Description         | Page | Reserved |
|-----------|----------|------------|------------|---------------------|------|----------|
| 0x0 – 0x2 | EEER     | 0x000043A0 | 0x00030000 | Enable Tx & Rx EEE. | 661  |          |

## 6.4.9 PHY Auto Configuration Module

This section is used to modify the PHY registers at power. It is built from a set of address/data words within the PHY register set ([Section 10.0](#)). The content is the value of the MSCA and MSRWD registers ([Section 8.2.2.16.4](#) and [Section 8.2.2.16.5](#)).

If the CRC8 is wrong or length is not valid, the section auto-load is skipped, the FWSM.EXT\_ERR\_IND is set to 0x23, and FWSM.PHY0\_CONFIG\_\_ERR\_IND, FWSM.PHY1\_CONFIG\_\_ERR\_IND bits are set.

| Offset    | High Byte [15:8]           | Low Byte [7:0] | Page                |
|-----------|----------------------------|----------------|---------------------|
| 0x0       | Section Length = $3*n + 1$ |                | <a href="#">231</a> |
| 0x1       | CSR Address - MSCA[15:0]   |                | <a href="#">231</a> |
| 0x2       | CSR Address - MSCA[25:16]  |                | <a href="#">231</a> |
| 0x3       | Data - MSRWD[15:0]         |                | <a href="#">231</a> |
| 0x4       | Mask[15:0]                 |                | <a href="#">231</a> |
|           | ...                        |                |                     |
| $4*n - 3$ | CSR Address - MSCA[15:0]   |                | <a href="#">231</a> |
| $4*n - 2$ | CSR Address - MSCA[25:16]  |                | <a href="#">231</a> |
| $4*n - 1$ | Data - MSRWD[15:0]         |                | <a href="#">231</a> |
| $3*n$     | Mask[15:0]                 |                | <a href="#">231</a> |
| $3*n + 1$ | Section Footer             |                | <a href="#">231</a> |

### 6.4.9.1 Section Length — Offset 0x0

The section length word contains the length of the section in words. Note that section length does not include a count for the section length word.

| Bits | Name           | Default | Description              | Reserved |
|------|----------------|---------|--------------------------|----------|
| 15:0 | Section_length | 0x0     | Section length in words. |          |

### 6.4.9.2 CSR Address - MSCA[15:0] — Offset 0x1, 0x5, 0x8...

| Bits | Name       | Default | Description                     | Reserved |
|------|------------|---------|---------------------------------|----------|
| 15:0 | MSCA[15:0] | 0x0     | The value to set in MSCA[15:0]. |          |

### 6.4.9.3 CSR Address - MSCA[25:16] — Offset 0x2, 0x6, 0x9...

| Bits  | Name        | Default | Description                      | Reserved |
|-------|-------------|---------|----------------------------------|----------|
| 9:0   | MSCA[25:16] | 0x0     | The value to set in MSCA[25:16]. |          |
| 15:10 | Reserved    | 0x0     | Reserved.                        |          |

### 6.4.9.4 CSR Data - MSRWD — Offset 0x3, 0x7, 0xA...

| Bits | Name        | Default | Description                        | Reserved |
|------|-------------|---------|------------------------------------|----------|
| 15:0 | MSRWD[15:0] | 0x0     | The value to set into MSRWD[15:0]. |          |

### 6.4.9.5 CSR Mask - Offset 0x4, 0x8, 0xB...

| Bits | Name        | Default | Description                                    | Reserved |
|------|-------------|---------|------------------------------------------------|----------|
| 15:0 | MSRWM[15:0] | 0x0     | The mask value to use when writing MSRWD[15:0] |          |

### 6.4.9.6 Section Footer

| Bits | Name     | Default | Description                | Reserved |
|------|----------|---------|----------------------------|----------|
| 7:0  | Reserved | 0x0     | Reserved.                  |          |
| 15:8 | CRC 8    |         | CRC8 of the section above. |          |

**Table 6-5. Auto-Loaded CSRs**

| Offset    | CSR Name                                            | MSCA       | MSRWD                                | Mask | Description         | Page                | Reserved |
|-----------|-----------------------------------------------------|------------|--------------------------------------|------|---------------------|---------------------|----------|
| 0x1 – 0x3 | PMA Receive Reserved Vendor Provisioning 1 - port 0 | 0x0001E400 | 0x2 (not reversed)<br>0x3 (reversed) | 0x3  | Swap lanes - port 0 | <a href="#">772</a> |          |
| 0x5 – 0x7 | PMA Receive Reserved Vendor Provisioning 1 - port 1 | 0x0021E400 | 0x2 (not reversed)<br>0x3 (reversed) | 0x3  | Swap lanes - port 1 | <a href="#">772</a> |          |

**Note:** The following settings should be done in the PHY provisioning area:

| CSR Name                                 | MSCA       | MSRWD  | Description                                   | Page                |
|------------------------------------------|------------|--------|-----------------------------------------------|---------------------|
| Global Interrupt Chip-Wide Vendor Mask   | 0x001EFF01 | 0x5    | TS NVM mode interrupts.                       | <a href="#">836</a> |
| Global Interrupt Chip-Wide Standard Mask | 0x001EFF00 | 0x1    | TS NVM mode interrupts.                       | <a href="#">835</a> |
| Global Thermal Provisioning 2            | 0x001EC421 | 0x6600 | Set Temperature Threshold to 107 °C.          | <a href="#">813</a> |
| Global Thermal Provisioning 4            | 0x001EC423 | 0x6600 | Set Temperature Threshold to 107 °C.          | <a href="#">813</a> |
| Global Thermal Provisioning 6            | 0x001EC475 | 0x8050 | Set High temperature failure as TS indicator. | <a href="#">815</a> |

## 6.5 Firmware Sections

The Firmware Module is formed by a header and sub-modules. Each of the modules handled by the firmware (apart from the firmware image) has the following format:

| Module Offset    | Content | Description                                                                                                                                   |
|------------------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| 0x0              | Header  | Length in words (including the CRC word but not the header word (length)).                                                                    |
| 0x1 – Length - 2 | Module  | Module Content                                                                                                                                |
| Length - 1       | Footer  | Bits[15:8] = CRC8 on the entire section (including the length).<br>The CRC polynomial used is: $X^8 + X^2 + X + 1$ .<br>Bits[7:0] = Reserved. |
| 0xC              |         | Reserved.                                                                                                                                     |

### 6.5.1 Firmware Module Header

Content of the header is listed in [Table 6-6](#). It is a list of pointers to all the firmware sub-modules. All the pointers in this section are relative to the location of the pointer.

**Table 6-6. Firmware Module Header**

| Global MNG Word Offset | Description                               | Page                |
|------------------------|-------------------------------------------|---------------------|
| 0x0                    | Header                                    | <a href="#">233</a> |
| 0x1                    | Reserved                                  |                     |
| 0x2                    | Common Firmware Parameters Pointer        | <a href="#">234</a> |
| 0x3                    | Pass-Through LAN 0 Configuration Pointer  | <a href="#">235</a> |
| 0x4                    | Sideband Configuration Pointer            | <a href="#">242</a> |
| 0x5                    | Flexible TCO Filter Configuration Pointer | <a href="#">248</a> |
| 0x6                    | Pass-Through LAN 1 Configuration Pointer  | <a href="#">235</a> |
| 0x7                    | Reserved                                  |                     |
| 0x8                    | Section Footer                            | <a href="#">233</a> |

#### 6.5.1.1 Section Header — Offset 0x0

| Bits | Name         | Default | Description                                                             | Reserved |
|------|--------------|---------|-------------------------------------------------------------------------|----------|
| 15:0 | Block Length | 0x8     | Block length in words (including the CRC word and not the length word). |          |

#### 6.5.1.2 Section Footer — Offset 0x8

| Bits | Name     | Default | Description                | Reserved |
|------|----------|---------|----------------------------|----------|
| 7:0  | Reserved | 0x0     | Reserved.                  |          |
| 15:8 | CRC 8    |         | CRC8 of the section above. |          |

## 6.5.2 Common Firmware Parameters Module — Global MNG Offset 0x2

### 6.5.2.1 Section Header — Offset 0x0

| Bits | Name         | Default | Description                                                             | Reserved |
|------|--------------|---------|-------------------------------------------------------------------------|----------|
| 15:0 | Block Length | 0x3     | Block length in words (including the CRC word and not the length word). |          |

### 6.5.2.2 Common Firmware Parameters — Offset 0x1

| Bits  | Name                           | Default | Description                                                                                                                                                                                         | Reserved |
|-------|--------------------------------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 0     | LAN0 TCO Isolate Disable       | 1b      | LAN0 TCO Isolate Disable<br>0b = Enable TCO Isolate on LAN0.<br>1b = Disable TCO Isolate on LAN0.                                                                                                   |          |

### 6.5.2.3 Common Firmware Parameters 2 — Offset 0x2

| Bits  | Name                            | Default | Description                                                                                                                                                                                                     | Reserved |
|-------|---------------------------------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 0     | Reserved                        | 0b      | Reserved.                                                                                                                                                                                                       |          |
| 5:1   | NVM Semaphore Back-off Interval | 0x2     | Number of 100 $\mu$ s ticks that firmware must wait before taking NVM semaphore ownership again since it has released it.                                                                                       |          |
| 10:6  | Reserved                        | 0x0     | Reserved. Must be set to 0x0.                                                                                                                                                                                   |          |
| 11    | Multi-Drop NC-SI                | 1b      | Multi-Drop NC-SI Topology.<br>0b = Point-to-point.<br>1b = Multi-drop (default).<br>When this bit is set, the NCSI_CRS_DV and NCSI_RXD[1:0] pins are High-Z following power-up; otherwise, the pins are driven. |          |
| 15:12 | Reserved                        | 0x0     | Reserved.                                                                                                                                                                                                       |          |

### 6.5.2.4 Section Footer — Offset 0x3

| Bits | Name     | Default | Description                | Reserved |
|------|----------|---------|----------------------------|----------|
| 7:0  | Reserved | 0x0     | Reserved.                  |          |
| 15:8 | CRC 8    |         | CRC8 of the section above. |          |

## 6.5.3 Pass-Through LAN 0/1 Configuration Modules — Global MNG Offsets 0x03 and 0x06

The following sections describe pointers and structures dedicated to pass-through mode for LAN 0 and LAN 1. LAN 0 structure is pointed by the Firmware Module pointer at offset 0x3. LAN 1 structure is pointed by the Firmware Module pointer at offset 0x6 ([Table 6-6](#)).

### 6.5.3.1 Section Header — Offset 0x0

| Bits | Name         | Default | Description                                                             | Reserved |
|------|--------------|---------|-------------------------------------------------------------------------|----------|
| 7:0  | Block Length | 0x71    | Block length in words (including the CRC word and not the length word). |          |

### 6.5.3.2 LAN 0/1 IPv4 Address 0 (LSB) MIPAF0 — Offset 0x01

| Bits | Name       | Default | Description                     | Reserved |
|------|------------|---------|---------------------------------|----------|
| 7:0  | IPv4[7:0]  |         | LAN 0/1 IPv4 Address 0, Byte 0. |          |
| 15:8 | IPv4[15:8] |         | LAN 0/1 IPv4 Address 0, Byte 1. |          |

### 6.5.3.3 LAN 0/1 IPv4 Address 0 (MSB) MIPAF0 — Offset 0x02

| Bits | Name        | Default | Description                     | Reserved |
|------|-------------|---------|---------------------------------|----------|
| 7:0  | IPv4[23:15] |         | LAN 0/1 IPv4 Address 0, Byte 2. |          |
| 15:8 | IPv4[31:24] |         | LAN 0/1 IPv4 Address 0, Byte 3. |          |

#### 6.5.3.4 LAN 0/1 IPv4 Address 1 MIPAF1 — Offset 0x03-0x04

Same structure as LAN0 IPv4 Address 0 ([Section 6.5.3.2](#) and [Section 6.5.3.3](#)).

#### 6.5.3.5 LAN 0/1 IPv4 Address 2 MIPAF2 — Offset 0x05-0x06

Same structure as LAN0 IPv4 Address 0 ([Section 6.5.3.2](#) and [Section 6.5.3.3](#)).

#### 6.5.3.6 LAN 0/1 IPv4 Address 3 MIPAF3 — Offset 0x07-0x08

Same structure as LAN0 IPv4 Address 0 ([Section 6.5.3.2](#) and [Section 6.5.3.3](#)).

#### 6.5.3.7 LAN 0/1 Ethernet MAC Address 0 (LSB) MMAL0 — Offset 0x09

This word is loaded by firmware to the 16 LS bits of the MMAL[0][15:0] register (refer to [Section 8.2.2.19.11](#)).

| Bits | Name              | Default | Description                             | Reserved |
|------|-------------------|---------|-----------------------------------------|----------|
| 7:0  | MAC Address[7:0]  |         | LAN 0/1 Ethernet MAC Address 0, Byte 0. |          |
| 15:8 | MAC Address[15:8] |         | LAN 0/1 Ethernet MAC Address 0, Byte 1. |          |

#### 6.5.3.8 LAN 0/1 Ethernet MAC Address 0 (Mid) MMAL0 — Offset 0x0A

This word is loaded by firmware to the 16 MS bits of the MMAL[0][31:16] register (refer to [Section 8.2.2.19.11](#)).

| Bits | Name               | Default | Description                             | Reserved |
|------|--------------------|---------|-----------------------------------------|----------|
| 7:0  | MAC Address[23:16] |         | LAN 0/1 Ethernet MAC Address 0, Byte 2. |          |
| 15:8 | MAC Address[31:24] |         | LAN 0/1 Ethernet MAC Address 0, Byte 3. |          |

#### 6.5.3.9 LAN 0/1 Ethernet MAC Address 0 (MSB) MMAH0 — Offset 0x0B

This word is loaded by firmware to the MMAH[0][15:0] register (refer to [Section 8.2.2.19.12](#)).

| Bits | Name               | Default | Description                             | Reserved |
|------|--------------------|---------|-----------------------------------------|----------|
| 7:0  | MAC Address[39:32] |         | LAN 0/1 Ethernet MAC Address 0, Byte 4. |          |
| 15:8 | MAC Address[47:40] |         | LAN 0/1 Ethernet MAC Address 0, Byte 5. |          |

### 6.5.3.10 LAN 0/1 Ethernet MAC Address 1 MMAL/H1 — Offset 0x0C-0x0E

Same structure as LAN0 Ethernet MAC Address 0 ([Section 6.5.3.7](#), [Section 6.5.3.8](#), and [Section 6.5.3.9](#)). Loaded to MMAL[1], MMAH[1] ([Section 8.2.2.19.11](#) and [Section 8.2.2.19.12](#), respectively).

### 6.5.3.11 LAN 0/1 Ethernet MAC Address 2 MMAL/H2 — Offset 0x0F-0x11

Same structure as LAN0 Ethernet MAC Address 0 ([Section 6.5.3.7](#), [Section 6.5.3.8](#), and [Section 6.5.3.9](#)). Loaded to MMAL[2], MMAH[2] ([Section 8.2.2.19.11](#) and [Section 8.2.2.19.12](#), respectively).

### 6.5.3.12 LAN 0/1 Ethernet MAC Address 3 MMAL/H3 — Offset 0x12-0x14

Same structure as LAN0 Ethernet MAC Address 0 ([Section 6.5.3.7](#), [Section 6.5.3.8](#), and [Section 6.5.3.9](#)). Loaded to MMAL[3], MMAH[3] ([Section 8.2.2.19.11](#) and [Section 8.2.2.19.12](#), respectively).

### 6.5.3.13 LAN 0/1 TCP/UDP Flexible Filter Ports 0-15 (MFUTP Registers) — Offset 0x15-0x24

| Offset | Bits | Description                               | Reserved |
|--------|------|-------------------------------------------|----------|
| 0x15   | 15:0 | LAN TCP/UDP Flexible Filter Value Port0.  |          |
| 0x16   | 15:0 | LAN TCP/UDP Flexible Filter Value Port1.  |          |
| 0x17   | 15:0 | LAN TCP/UDP Flexible Filter Value Port2.  |          |
| 0x18   | 15:0 | LAN TCP/UDP Flexible Filter Value Port3.  |          |
| 0x19   | 15:0 | LAN TCP/UDP Flexible Filter Value Port4.  |          |
| 0x1A   | 15:0 | LAN TCP/UDP Flexible Filter Value Port5.  |          |
| 0x1B   | 15:0 | LAN TCP/UDP Flexible Filter Value Port6.  |          |
| 0x1C   | 15:0 | LAN TCP/UDP Flexible Filter Value Port7.  |          |
| 0x1D   | 15:0 | LAN TCP/UDP Flexible Filter Value Port8.  |          |
| 0x1E   | 15:0 | LAN TCP/UDP Flexible Filter Value Port9.  |          |
| 0x1F   | 15:0 | LAN TCP/UDP Flexible Filter Value Port10. |          |
| 0x20   | 15:0 | LAN TCP/UDP Flexible Filter Value Port11. |          |
| 0x21   | 15:0 | LAN TCP/UDP Flexible Filter Value Port12. |          |
| 0x22   | 15:0 | LAN TCP/UDP Flexible Filter Value Port13. |          |
| 0x23   | 15:0 | LAN TCP/UDP Flexible Filter Value Port14. |          |
| 0x24   | 15:0 | LAN TCP/UDP Flexible Filter Value Port15. |          |

### 6.5.3.14 LAN 0/1 VLAN Filter 0-7 (MAVTV Registers) — Offset 0x25-0x2C

| Offset | Bits  | Description                  | Reserved |
|--------|-------|------------------------------|----------|
| 0x25   | 15:12 | Reserved.                    |          |
| 0x25   | 11:0  | LAN 0/1 VLAN Filter 0 Value. |          |
| 0x26   | 15:12 | Reserved.                    |          |
| 0x26   | 11:0  | LAN 0/1 VLAN Filter 1 Value. |          |
| 0x27   | 15:12 | Reserved.                    |          |
| 0x27   | 11:0  | LAN 0/1 VLAN Filter 2 Value. |          |
| 0x28   | 15:12 | Reserved.                    |          |
| 0x28   | 11:0  | LAN 0/1 VLAN Filter 3 Value. |          |
| 0x29   | 15:12 | Reserved.                    |          |
| 0x29   | 11:0  | LAN 0/1 VLAN Filter 4 Value. |          |
| 0x2A   | 15:12 | Reserved.                    |          |
| 0x2A   | 11:0  | LAN 0/1 VLAN Filter 5 Value. |          |
| 0x2B   | 15:12 | Reserved.                    |          |
| 0x2B   | 11:0  | LAN 0/1 VLAN Filter 6 Value. |          |
| 0x2C   | 15:12 | Reserved.                    |          |
| 0x2C   | 11:0  | LAN 0/1 VLAN Filter 7 Value. |          |

### 6.5.3.15 LAN 0/1 MANC Value LSB (LMANC LSB) — Offset 0x2D

| Bits | Name     | Default | Description | Reserved |
|------|----------|---------|-------------|----------|
| 15:0 | Reserved | 0x0     | Reserved.   |          |

### 6.5.3.16 LAN 0/1 MANC Value MSB (LMANC MSB) — Offset 0x2E

| Bits  | Name                         | Default | Description                                                                                    | Reserved |
|-------|------------------------------|---------|------------------------------------------------------------------------------------------------|----------|
| 6:0   | Reserved                     | 0x0     | Reserved.                                                                                      |          |
| 7     | Enable Xsum Filtering to MNG | 1b      | This bit is loaded to the <i>EN_XSUM_FILTER</i> bit in the MANC register (Section 8.2.2.19.7). |          |
| 8     | Enable IPv4 Address Filters  | 1b      | This bit is loaded to the <i>EN_IPv4_FILTER</i> bit in the MANC register.                      |          |
| 9     | FIXED NET TYPE               | 0b      | This bit is loaded to the <i>FIXED_NET_TYPE</i> bit in the MANC register.                      |          |
| 10    | NET TYPE                     | 0b      | This bit is loaded to the <i>NET_TYPE</i> bit in the MANC register.                            |          |
| 15:11 | Reserved                     | 0x0     | Reserved.                                                                                      |          |

### 6.5.3.17 LAN 0/1 Receive Enable 1 (LRXEN1) — Offset 0x2F

| Bits | Name                     | Default | Description                                                                                                                                                                                           | Reserved |
|------|--------------------------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 0    | Enable Receive TCO       |         |                                                                                                                                                                                                       |          |
| 1    | Reserved                 | 0b      | Reserved. Must be set to 0b.                                                                                                                                                                          |          |
| 2    | Enable Status Reporting  |         |                                                                                                                                                                                                       |          |
| 3    | Enable ARP Response      |         |                                                                                                                                                                                                       |          |
| 5:4  | Notification method      |         | This field is valid only in the section of Port 0, and defines the notification method for all ports.<br>00b = SMBus alert.<br>01b = Asynchronous notify.<br>10b = Direct receive.<br>11b = Reserved. |          |
| 6    | Reserved                 | 1b      | Reserved. Must be set to 1b.                                                                                                                                                                          |          |
| 7    | Enable BMC Dedicated MAC |         |                                                                                                                                                                                                       |          |
| 15:8 | Receive Enable byte 12   |         | MC SMBus slave address.                                                                                                                                                                               |          |

### 6.5.3.18 LAN 0/1 Receive Enable 2 (LRXEN2) — Offset 0x30

| Bits | Name                   | Default | Description     | Reserved |
|------|------------------------|---------|-----------------|----------|
| 7:0  | Receive Enable byte 13 | 0x0     | Interface data. |          |
| 15:8 | Receive Enable byte 14 | 0x0     | Alert value.    |          |

### 6.5.3.19 LAN 0/1 MNGONLY Value (MNGONLY LSB) — Offset 0x31

| Bits | Name             | Default | Description                                                                                                                                                    | Reserved |
|------|------------------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 7:0  | Exclusive to MNG | 0x0     | When set, indicates that packets forwarded by the manageability filters to manageability are not sent to the host. Bit[0] corresponds to decision rule 0, etc. |          |
| 15:8 | Reserved         | 0x0     | Reserved.                                                                                                                                                      |          |

### 6.5.3.20 LAN 0/1 MNGONLY Value (MNGONLY MSB) — Offset 0x32

| Bits | Name     | Default | Description | Reserved |
|------|----------|---------|-------------|----------|
| 15:0 | Reserved | 0x0     | Reserved.   |          |

### 6.5.3.21 Manageability Decision Filters - MDEF0 (1) — Offset 0x33

| Bits | Name    | Default | Description                                                                      | Reserved |
|------|---------|---------|----------------------------------------------------------------------------------|----------|
| 15:0 | MDEF0_L | 0x0     | Loaded to 16 LS bits of MDEF[0] register ( <a href="#">Section 8.2.2.19.9</a> ). |          |

### 6.5.3.22 Manageability Decision Filters - MDEF0 (2) — Offset 0x34

| Bits | Name    | Default | Description                                                                      | Reserved |
|------|---------|---------|----------------------------------------------------------------------------------|----------|
| 15:0 | MDEF0_M | 0x0     | Loaded to 16 MS bits of MDEF[0] register ( <a href="#">Section 8.2.2.19.9</a> ). |          |

### 6.5.3.23 Manageability Decision Filters - MDEF0 (3) — Offset 0x35

| Bits | Name       | Default | Description                                                                          | Reserved |
|------|------------|---------|--------------------------------------------------------------------------------------|----------|
| 15:0 | MDEFEXT0_L | 0x0     | Loaded to 16 LS bits of MDEF_EXT[0] register ( <a href="#">Section 8.2.2.19.5</a> ). |          |

### 6.5.3.24 Manageability Decision Filters - MDEF0 (4) — Offset 0x36

| Bits | Name       | Default | Description                                                                          | Reserved |
|------|------------|---------|--------------------------------------------------------------------------------------|----------|
| 15:0 | MDEF0EXT_M | 0x0     | Loaded to 16 MS bits of MDEF_EXT[0] register ( <a href="#">Section 8.2.2.19.5</a> ). |          |

### 6.5.3.25 Manageability Decision Filters - MDEF1-6 (1-4) — Offset 0x37-0x4E

Same as words 0x035...0x38 for MDEF[1] and MDEF\_EXT[1]...MDEF[6] and MDEF\_EXT[6] (see [Section 8.2.2.19.9](#) and [Section 8.2.2.19.5](#), respectively).

### 6.5.3.26 Manageability Ethertype Filter 0.1 - METF0 (1) — Offset 0x4F

| Bits | Name    | Default | Description                                                                      | Reserved |
|------|---------|---------|----------------------------------------------------------------------------------|----------|
| 15:0 | METF0_L | 0x0     | Loaded to 16 LS bits of METF[0] register ( <a href="#">Section 8.2.2.19.6</a> ). |          |

### 6.5.3.27 Manageability Ethertype Filter 0.2 - METF0 (2) — Offset 0x50

| Bits | Name    | Default | Description                                                                                                                                                                   | Reserved |
|------|---------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 15:0 | METF0_M | 0x0     | Loaded to 16 MS bits of METF[0] register (Section 8.2.2.19.6).<br><b>Note:</b> Reserved bits in the METF registers should be set in the NVM to the register's default values. |          |

### 6.5.3.28 Manageability Ethertype Filter 1...3 (1 and 2) - METF1...3 — Offset 0x51-0x56

Same as words 0x51 and 0x52 for METF[1]...METF[3] registers (see Section 8.2.2.19.6).

### 6.5.3.29 ARP Response IPv4 Address 0 (LSB) — Offset 0x57

These values override the value in LAN IPv4 Address 3 (Section 6.5.3.6) if *Enable ARP Response* in LRXEN1 is set (Section 6.5.3.17).

| Bits | Name           | Default | Description                                         | Reserved |
|------|----------------|---------|-----------------------------------------------------|----------|
| 7:0  | ARP IPv4[7:0]  |         | ARP Response IPv4 Address 0, Byte 0 (firmware use). |          |
| 15:8 | ARP IPv4[15:8] |         | ARP Response IPv4 Address 0, Byte 1 (firmware use). |          |

### 6.5.3.30 ARP Response IPv4 Address 0 (MSB) — Offset 0x58

These values are stored in the MIPAF[0] register (0x58B0). Refer to Section 8.2.2.19.10 for a description of this register.

| Bits | Name            | Default | Description                                         | Reserved |
|------|-----------------|---------|-----------------------------------------------------|----------|
| 7:0  | ARP IPv4[23:19] |         | ARP Response IPv4 Address 0, Byte 2 (firmware use). |          |
| 15:8 | ARP IPv4[31:24] |         | ARP Response IPv4 Address 0, Byte 3 (firmware use). |          |

### 6.5.3.31 LAN 0/1 IPv6 Address 0 (MIPAF.IPV6ADDR0) — Offset 0x59-0x60

| Bits | Name | Default | Description                                                                                                                               | Reserved |
|------|------|---------|-------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 15:0 | IPv6 |         | Loaded to MIPAF registers IPV6ADDR0: DWORD offset 'n'/2 to the lower 16 bits for even 'n' and upper 16 bits for odd 'n'. For 'n' = 0...7. |          |

### 6.5.3.32 LAN 0/1 IPv6 Address 1 (MIPAF.IPV6ADDR1) — Offset 0x61-0x68

Same structure as LAN 0/1 IPv6 Address 0 (see Section 6.5.3.31).

### 6.5.3.33 LAN 0/1 IPv6 Address 2 (MIPAF) — Offset 0x69-0x70

Same structure as LAN 0/1 IPv6 Address 0 (see [Section 6.5.3.31](#)).

### 6.5.3.34 Section Footer — Offset 0x71

| Bits | Name     | Default | Description                | Reserved |
|------|----------|---------|----------------------------|----------|
| 7:0  | Reserved | 0x0     | Reserved.                  |          |
| 15:8 | CRC 8    |         | CRC8 of the section above. |          |

## 6.5.4 Sideband Configuration Module — Global MNG Offset 0x04

This module is pointed to by global offset 0x04 of the manageability control table.

### 6.5.4.1 Section Header — Offset 0x00

| Bits | Name         | Default | Description                                                               | Reserved |
|------|--------------|---------|---------------------------------------------------------------------------|----------|
| 15:0 | Block Length | 0x15    | Section length in words (including the CRC word and not the length word). |          |

### 6.5.4.2 SMBus Maximum Fragment Size — Offset 0x01

| Bits | Name              | Default                          | Description                                                                                                                                                                                      | Reserved |
|------|-------------------|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 15:0 | Max Fragment Size | Legacy SMBus: 0x20<br>MCTP: 0x45 | SMBus Maximum Fragment Size (bytes).<br>Supported range is between 32 and 240 bytes.<br><b>Note:</b> In MCTP mode, this value should be set to 0x45 (64 bytes payload + 5 bytes of MCTP header). |          |

### 6.5.4.3 SMBus Notification Timeout and Flags — Offset 0x02

| Bits | Name                            | Default | Description                                                                                                                                                                                                                                                                                                                                                                                           | Reserved |
|------|---------------------------------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 0    | SMBus Transaction PEC           | 0b      | SMBus Transactions PEC<br>Should be set in MCTP modes.<br>0b = Disable PEC — If this bit is cleared, PEC is not added to master write or slave read transactions, a slave write transaction with PEC is dropped.<br>1b = Enable PEC — If this bit is set, PEC is added for master SMBus write transactions, a PEC is added to slave read transactions and can be received in slave write transaction. |          |
| 1    | SMBus ARP PEC                   | 1b      | SMBus ARP PEC.<br>Should be set.<br>0b = Disable SMBus ARP PEC.<br>1b = Enable SMBus ARP PEC.                                                                                                                                                                                                                                                                                                         |          |
| 2    | Disable SMBus ARP Functionality | 0b      | Disable SMBus ARP Functionality<br>0b = SMBus ARP is enabled.<br>1b = SMBus ARP is disabled.                                                                                                                                                                                                                                                                                                          |          |

| Bits | Name                            | Default | Description                                                                                                                                     | Reserved |
|------|---------------------------------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 3    | Enable Fairness Arbitration     | 0b      | Enable Fairness Arbitration<br>0b = Disable fairness arbitration.<br>1b = Enable fairness arbitration.                                          |          |
| 4    | Reserved                        | 1b      | Reserved. Must be set to 1b.                                                                                                                    |          |
| 5    | SMBus Block Read Command        | 0b      | SMBus Block Read Command<br>0b = Block read command is 0xC0.<br>1b = Block read command is 0xD0.                                                |          |
| 7:6  | SMBus Connection Speed          | 00b     | SMBus Connection Speed<br>00b = Standard SMBus connection (100 KHz).<br>01b = 400 KHz connection.<br>10b = 1 MHz connection.<br>11b = Reserved. |          |
| 15:8 | SMBus Notification Timeout (ms) | 0xFF    | <b>Note:</b> The actual timeout can vary up to 1 ms below the set value.                                                                        |          |

#### 6.5.4.4 SMBus Slave Addresses — Offset 0x03

| Bits | Name                  | Default | Description               | Reserved |
|------|-----------------------|---------|---------------------------|----------|
| 0    | Reserved              | 0b      | Reserved.                 |          |
| 7:1  | SMBus 0 Slave Address | 0x63    | SMBus Address for port 0. |          |
| 8    | Reserved              | 0b      | Reserved.                 |          |
| 15:9 | SMBus 1 Slave Address | 0x62    | SMBus Address for port 1. |          |

#### 6.5.4.5 NC-SI Configuration 1 — Offset 0x04

| Bits  | Name                              | Default                                                            | Description                                                                                                                       | Reserved |
|-------|-----------------------------------|--------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|----------|
| 4:0   | Reserved                          | 0x0                                                                | Reserved. Must be set to 0x0.                                                                                                     |          |
| 7:5   | Package ID                        | 0b                                                                 | Meaningful only when bit 15 of <i>NC-SI Configuration 2</i> word (offset 0x05) is cleared (see <a href="#">Section 6.5.4.6</a> ). |          |
| 8     | NC-SI HW-based Packet Copy Enable | 1b                                                                 | NC-SI Hardware-based Packet Copy Enable<br>0b = Disable<br>1b = Enable                                                            |          |

| 3:0  | Max XOFF Renewal          | 0x6     | NC-SI Flow Control MAX XOFF Renewal (# of XOFF renewals allowed).<br>0x0 = Disabled. Unlimited number of XOFF frames can be sent.<br>0x1 = Up to 2 consecutive XOFFs frames can be sent by the device.<br>0x2 = Up to 3 consecutive XOFFs frames can be sent by the device.<br>...<br>0xF = Up to 0x10 consecutive XOFFs frames can be sent by the device. |          |
| 14:4 | Reserved                  | 0x0     | Reserved.                                                                                                                                                                                                                                                                                                                                                  |          |
| 15   | NC-SI Package ID from SDP | 0b      | Read NC-SI Package ID from:<br>0b = NVM — NC-SI Configuration 1 word bits 7:5 (offset 0x06).<br>1b = SDP — SDPn_0 pin of LAN port,0. The package ID is {0, SDP0_0, 0}                                                                                                                                                                                      |          |

#### 6.5.4.7 NC-SI Flow Control XOFF — Offset 0x06

| Bits | Name           | Default | Description                                                                                                                                                                                                                                                                                                                                                                                                                     | Reserved |
|------|----------------|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 15:0 | XOFF Threshold | 0x12C0  | Tx buffer watermark for sending a XOFF NC-SI flow control packet in bytes.<br>The <i>XOFF Threshold</i> value refers to the occupied space in the buffer.<br>The value should be 16 bytes aligned.<br><b>Notes:</b><br>1. Field relevant for NC-SI operation mode only.<br>2. To support a maximum packet size of 1.5 KB, the value programmed assuming a Tx buffer size of 8 KB value of field should be 0x12C0 (4,800 bytes). |          |

#### 6.5.4.8 NC-SI Flow Control XON — Offset 0x07

| Bits | Name          | Default | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Reserved |
|------|---------------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 15:0 | XON Threshold | 0x1340  | Tx buffer water mark for sending a XON NC-SI flow control packet in bytes.<br>The <i>XON Threshold</i> value refers to the available space in the Tx buffer.<br>The value should be 16 bytes aligned.<br><b>Notes:</b><br>1. Field relevant for NC-SI operation mode only.<br>2. To support maximum packet size of 1.5 KB, the value programmed should be a positive value that equals: <i>XOFF Threshold</i> + 1536 bytes. Assuming a <i>Tx Buffer size</i> is 8 KB and the <i>XOFF Threshold</i> (Section 6.5.4.7) is 4,800 bytes, the value of field should be 0x1340 (4,928 bytes). |          |

#### 6.5.4.9 NC-SI Hardware Arbitration Configuration — Offset 0x08

| Bits | Name          | Default | Description                                                                                                              | Reserved |
|------|---------------|---------|--------------------------------------------------------------------------------------------------------------------------|----------|
| 15:0 | Token Timeout | 0xA000  | NC-SI Hardware Arbitration TOKEN Timeout (in REF_CLK - 20 ns cycles). Setting value to 0 disables the timeout mechanism. |          |

#### 6.5.4.10 MCTP UUID - Time Low LSB — Offset 0x09

The value stored in the MCTP UUID register should indicate the creation date of the image or an earlier arbitrary date.

| Bits | Name         | Default | Description                               | Reserved |
|------|--------------|---------|-------------------------------------------|----------|
| 15:0 | time low LSB |         | Byte 0 & 1 of UUID as defined in DSP0236. |          |

#### 6.5.4.11 MCTP UUID - Time Low MSB — Offset 0x0A

| Bits | Name         | Default | Description                               | Reserved |
|------|--------------|---------|-------------------------------------------|----------|
| 15:0 | time low MSB |         | Byte 2 & 3 of UUID as defined in DSP0236. |          |

#### 6.5.4.12 MCTP UUID - Time MID — Offset 0x0B

| Bits | Name     | Default | Description                               | Reserved |
|------|----------|---------|-------------------------------------------|----------|
| 15:0 | time mid |         | Byte 4 & 5 of UUID as defined in DSP0236. |          |

#### 6.5.4.13 MCTP UUID - Time High and Version — Offset 0x0C

| Bits | Name                  | Default | Description                               | Reserved |
|------|-----------------------|---------|-------------------------------------------|----------|
| 15:0 | time high and version |         | Byte 7 & 8 of UUID as defined in DSP0236. |          |

#### 6.5.4.14 MCTP UUID - Clock Seq — Offset 0x0D

| Bits | Name                   | Default | Description                                | Reserved |
|------|------------------------|---------|--------------------------------------------|----------|
| 15:0 | Clock seq and reserved |         | Byte 9 & 10 of UUID as defined in DSP0236. |          |

#### 6.5.4.15 OEM IANA — Offset 0x0E

| Bits | Name                    | Default | Description                                                                                                                                                                                                                                                                                                       | Reserved |
|------|-------------------------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 15:0 | Alternative IANA number | 0x0     | If not zero and not 0x157, the X550 accepts additional OEM commands with this IANA number. These commands are accepted only if the OEM NVM Structure Pointer is valid. The set of commands accepted depends on the IANA value in this field.<br>The regular Intel OEM commands are accepted only with IANA 0x157. |          |

#### 6.5.4.16 NC-SI over MCTP Message Types — Offset 0x0F

| Bits | Name                           | Default | Description                                                               | Reserved |
|------|--------------------------------|---------|---------------------------------------------------------------------------|----------|
| 7:0  | NC-SI Pass Through packet type | 0x3     | Defines the MCTP packet type used to identify NC-SI Pass-Through Packets. |          |
| 15:8 | NC-SI Command packet type      | 0x2     | Defines the MCTP packet type used to identify NC-SI Control Packets.      |          |

#### 6.5.4.17 NC-SI over MCTP Configuration — Offset 0x10

| Bits | Name            | Default | Description                                                                                                 | Reserved |
|------|-----------------|---------|-------------------------------------------------------------------------------------------------------------|----------|
| 4:0  | Reserved        | 0x0     | Reserved.                                                                                                   |          |
| 5    | Disable ACLs    | 1b      | If set, the ACLs on the PCIe VDMs are disabled.                                                             |          |
| 6    | Simplified MCTP | 0b      | If set, only SOM & EOM bits are used for the reassembly process. Relevant only in MCTP over SMBus only mode |          |
| 15:7 | Reserved        | 0x0     | Reserved.                                                                                                   |          |

#### 6.5.4.18 Traffic Type Parameters — Offset 0x11

| Bits | Name                 | Default | Description                                                                                                                                                                                                                                                                                                                                                                               | Reserved |

| 1:0  | Port 0 traffic types | 01b     | This field is valid only if the <i>Port0 Manageability Capable</i> field in the <i>Common Firmware Parameters</i> NVM word ( <a href="#">Section 6.5.2</a> ) is set.<br>00b = Reserved.<br>01b = Network to BMC traffic only allowed through port 0.<br>10b = OS2BMC traffic only allowed through port 0.<br>11b = Both Network to BMC traffic and OS2BMC traffic allowed through port 0. |          |
| 3:2  | Reserved             | 0b      | Reserved.                                                                                                                                                                                                                                                                                                                                                                                 |          |
| 5:4  | Port 1 traffic types | 01b     | This field is valid only if the <i>Port1 Manageability Capable</i> field in the <i>Common Firmware Parameters</i> NVM word ( <a href="#">Section 6.5.2</a> ) is set.<br>00b = Reserved.<br>01b = Network to BMC traffic only allowed through port 1.<br>10b = OS2BMC traffic only allowed through port 1.<br>11b = Both Network to BMC traffic and OS2BMC traffic allowed through port 1. |          |
| 15:6 | Reserved             | 0b      | Reserved.                                                                                                                                                                                                                                                                                                                                                                                 |          |

#### 6.5.4.19 MCTP Rate Limiter Config 1 — Offset 0x12

| Bits | Name      | Default | Description                                                                                                                                                                                                    | Reserved |
|------|-----------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 15:0 | MCTP Rate | 0x2800  | Defines the number of cycles between accesses of the MCTP send client to the memory arbiter.<br>Default value assumes a clock of 80 MHz and a bus width of 128 bits. This value provides a bit rate of 1 Mb/s. |          |

### 6.5.4.20 MCTP Rate Limiter Config 2 — Offset 0x13

| Bits | Name             | Default | Description                                                                                                                                       | Reserved |
|------|------------------|---------|---------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 14:0 | MCTP max credits | 0x5     | Defines the maximum number of 16-bytes credit that can be accumulated. These credits include the VDM header line (one line for each 64 byte VDM). |          |
| 15   | Decision Point   | 0b      | Defines if, when credits are available, a full MCTP message is sent or a single VDM is sent.<br>0b = Per Packet<br>1b = Per VDM                   |          |

### 6.5.4.21 NC-SI Channel to Port Mapping — 0x14

Defines the mapping of NC-SI channels to physical ports.

| Bits | Name                   | Default | Description                                                              | Reserved |
|------|------------------------|---------|--------------------------------------------------------------------------|----------|
| 0    | Port #0 Channel Enable | 1b      | Valid values are:<br>0b = Disabled<br>1b = Enabled                       |          |
| 2:1  | Port #0 channel ID     | 00b     | The channel ID to use for port 0. Values of 0x2 & 0x3 are reserved.      |          |
| 3    | Reserved               | 0b      | Reserved.                                                                |          |
| 4    | Port #1 Channel Enable | 1b      | Valid values are:<br>0b = Disabled<br>1b = Enabled                       |          |
| 6:5  | Port #1 channel ID     | 01b     | The Channel ID to use for port 1. Values of 0x2 & 0x3 are reserved.      |          |
| 14:7 | Reserved               | 0x0     | Reserved.                                                                |          |
| 15   | Table Valid            | 0b      | If set, the values below are used to define the port to channel mapping. |          |

**Note:** The list of channel IDs must starts at zero and be consecutive.

### 6.5.4.22 Section Footer — Offset 0x15

| Bits | Name     | Default | Description                | Reserved |
|------|----------|---------|----------------------------|----------|
| 7:0  | Reserved | 0x0     | Reserved.                  |          |
| 15:8 | CRC 8    |         | CRC8 of the section above. |          |

## 6.5.5 Flexible TCO Filter Configuration Module — Global MNG Offset 0x05

### 6.5.5.1 Section Header — Offset 0x0

| Bits | Name         | Default           | Description                                                               | Reserved |
|------|--------------|-------------------|---------------------------------------------------------------------------|----------|
| 15:0 | Block Length | 0x4A <sup>1</sup> | Section length in words (including the CRC word and not the length word). |          |

1. Assuming a single filter.

### 6.5.5.2 Flexible Filter Length and Control — Offset 0x01

| Bits | Name                           | Default | Description                                                                                                        | Reserved |
|------|--------------------------------|---------|--------------------------------------------------------------------------------------------------------------------|----------|
| 0    | Apply Filter to LAN 0          |         | Apply Filter to LAN 0.<br>0b = Filter not applicable for LAN0 traffic.<br>1b = Filter applicable for LAN0 traffic. |          |
| 1    | Apply Filter to LAN 1          |         | Apply Filter to LAN 1.<br>0b = Filter not applicable for LAN1 traffic.<br>1b = Filter applicable for LAN1 traffic. |          |
| 3:2  | Filter Index (0)               | 0b      | Must be zero.                                                                                                      |          |
| 4    | Last Filter                    | 1b      | Must always be set if structure is present (single filter).                                                        |          |
| 7:5  | Reserved                       | 0b      | Reserved.                                                                                                          |          |
| 15:8 | Flexible Filter Length (bytes) |         | Flexible Filter Length (bytes).                                                                                    |          |

### 6.5.5.3 Flexible Filter Enable Mask — Offset 0x02-0x09

| Bits | Name                        | Default | Description                                   | Reserved |
|------|-----------------------------|---------|-----------------------------------------------|----------|
| 15:0 | Flexible Filter Enable Mask |         | Flexible Filter Enable Mask - 1 bit per byte. |          |

### 6.5.5.4 Flexible Filter Data — Offset 0x0A-0x49

| Bits | Name                 | Default | Description                                        | Reserved |
|------|----------------------|---------|----------------------------------------------------|----------|
| 15:0 | Flexible Filter Data |         | Flexible Filter Data - 128 bytes values to compare |          |

**Note:** This section loads all of the flexible filters. The control + mask + filter data are repeatable as the number of filters. Section length in offset 0 is for all filters.

### 6.5.5.5 Section Footer — Offset Block Length

| Bits | Name     | Default | Description                | Reserved |
|------|----------|---------|----------------------------|----------|
| 7:0  | Reserved | 0x0     | Reserved.                  |          |
| 15:8 | CRC 8    |         | CRC8 of the section above. |          |

## 6.5.6 Mini Loader Module

The mini loader module includes an initial firmware code used to load the full firmware image (Section 6.5.7). This module is stored in the Shadow RAM and is pointed to by word 0x42 in the NVM header. Word 0x0 in the module contains the size of the module while word 0x1 contains the location in the internal RAM to which the mini loader code is loaded. Words 0x3 - 0x5 contain the mini loader version information.

The format of the mini loader is as follows:

| Word Offset    | Description                                                                 |
|----------------|-----------------------------------------------------------------------------|
| 0x0            | Mini Loader Size in words (including the CRC word and excluding this word). |
| 0x1 – 0x2      | Mini Loader RAM location                                                    |
| 0x3            | Mini Loader Version - Major, Minor                                          |
| 0x4 – 0x5      | SVN Version                                                                 |
| 0x6 – Length-1 | Mini loader code                                                            |
| Length         | CRC 8 (bits 15:8)                                                           |

## 6.5.7 Firmware Image Module

The firmware image module contains the main code of the internal firmware loaded to the internal RAM. This module includes a header and a trailer. The header is used when the firmware is updated to authenticate it. The optional trailer includes a list of Read only words to be modified by the firmware or a new version of the first 16 KB of the NVM.

### 6.5.7.1 Header of Firmware Image Module

Since authenticated modules are by-definition not modifiable *in the fields*, no “holes” are present in such modules.

Table 6-7 shows the header of the Firmware Image module. Fields colored in light blue are protected by the authentication signature.

**Table 6-7. Header of Firmware and Option ROM Images**

| Byte Offset   | Number of Words | Field or Segment Name        | Description and Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------|-----------------|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x00 – 0x7F   | 64              | Authentication Header        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 0x80 – 0x17F  | 128             | RSA Public Key               | This field is skipped for the sake of SHA256 Hash computing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 0x180 – 0x183 | 2               | RSA Exponent                 | This field is skipped for the sake of SHA256 Hash computing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 0x184 – 0x283 | 128             | Encrypted SHA256 Hash        | This field is skipped for the sake of SHA256 Hash computing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 0x284 – 0x285 | 1               | X550 Blank NVM Device ID     | A unique ND-provided device ID that identifies the X550 controller among other ND controllers. It must be set to 0x1562 in the X550.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 0x286 – 0x289 | 2               | Max Module Area              | It is the maximum flash area expressed in words that can be used by the module, starting from authentication header (included). It is set to 256 K words (i.e. 512 KB) for all modules.                                                                                                                                                                                                                                                                                                                                                                       |
| 0x28A – 0x28D | 2               | Current Module Area          | It is the flash area expressed in words that is currently used by the module, starting from authentication header (included).                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 0x28E – 0x28F | 1               | Module Format Version + CRC8 | <p>Bit[15] = CRC8 field is used. Set to 1b if a CRC8 is computed over the module, set to 0b otherwise.</p> <p>Bits[14:8] = Module format version. Set to 0x02 is this currently defined format is used.</p> <p>Bits[7:0] = CRC8 value computed over the parent module only, starting from authentication header (included) and including all other module's fields and segments – excluding all descendant modules and <i>RSA Public Key/RSA Exponent</i> fields.</p> <p>CRC8 field is skipped for the sake of CRC8 computing (when bit 15 is set to 0b).</p> |
| 0x290 – 0x291 | 1               | Code Revision                | <p>Bits[15:8] = Major revision number.</p> <p>Bits[7:0] = Minor revision number.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 0x292 – 0x293 | 1               | Reserved Spare Word          | Must be zeroed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 0x294 – 0x297 | 2               | Parent Module Length         | <p>Length of the parent module contents expressed in words, module header and Parent Module Length field excluded. It excludes all the descendant modules. It must be set to N.</p> <p>Modules read by firmware are NOT size limited to 128 KB.</p> <p>It excludes the last 16 KB sector of the firmware image which is reserved for the RO Commands section.</p> <p>This field is not relevant for option ROM header and should be zeroed.</p>                                                                                                               |
| ...           | N               | parent word 1                | <p>Format of the contents of firmware modules is specific to each module.</p> <p>This field is not relevant for option ROM header and should be zeroed.</p>                                                                                                                                                                                                                                                                                                                                                                                                   |
|               |                 | parent word 2                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|               |                 | ...                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|               |                 | parent word N                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## 6.5.7.2 Trailer of the Firmware Image Module

Table 6-8 shows the format of the last 16 KB sector of the firmware image. Fields colored in light blue are protected by the authentication signature.

**Table 6-8. RO Commands Section Format**

| Number of Words | Field or Segment Name          | Description and Comments                                                                                                                                                                                                                                           |
|-----------------|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1               | RO Commands Version            | Default is 0xFFFF, which means the section is empty and the remaining words are discarded. A null field here indicates that the next words up to the 16 KB sector's end contain the new Shadow RAM contents, starting from word 0x000 up to word 0x01FF7 included. |
| 1               | X550 Blank NVM Device ID       | A unique ND-provided device ID that identifies the X550 controller among other ND controllers. It must be set to 0x1562 in the X550.                                                                                                                               |
| 1               | Minimum Firmware Code Revision | Minimum Firmware Code Revision number required for being able to parse the RO Commands section. It must be less than or equal to the Code Revision number read from the Firmware Image Header listed in Table 6-7.                                                 |
| 1               | RO Commands Length             | Length in words (N), starting from next word.                                                                                                                                                                                                                      |
| N               | RO Commands word 1             | Format of the RO Commands is described in Section 6.5.7.2.1.                                                                                                                                                                                                       |
|                 | RO Commands word 2             |                                                                                                                                                                                                                                                                    |
|                 | ...                            |                                                                                                                                                                                                                                                                    |
|                 | RO Commands word N             |                                                                                                                                                                                                                                                                    |

### 6.5.7.2.1 Format of the RO Commands

The RO Commands words can contains the following three structures:

- Shadow RAM Word Write Command (2 words)
- CSR Write Command (4 words)
- Shadow RAM contents, from word 0x0 to 0x1FF7 included

The first two structures starts with a type field.

Table 6-9 describes the different commands types:

**Table 6-9. RO Commands Types**

| Type  | Description                            |
|-------|----------------------------------------|
| xxx1b | Word auto-load.                        |
| 0100b | CSR auto-load with port number.        |
| Other | Invalid type, parsing is stopped here. |

|                           |                 |
|---------------------------|-----------------|
| Word Address[14:0]<br>15b | Type<br>1b=1'b1 |
| Word Data[15:0]<br>16b    |                 |

**Figure 6-2. Shadow RAM Word Write Command**

|                            |            |                    |
|----------------------------|------------|--------------------|
| CSR Address [11:2]<br>10b  | Port<br>2b | Type<br>4b=4'b0100 |
| CSR Address [27:12]<br>16b |            |                    |
| CSR Data[31:16]<br>16b     |            |                    |
| CSR Data[15:0]<br>16b      |            |                    |

**Figure 6-3. CSR Write Command (with Port Number)**

If the *Port* value is invalid, the command is ignored.

## 6.6 PCIe Expansion/Option ROM

This module might include the PXE driver, iSCSI boot and/or FCoE boot image, UEFI network driver, and a Command Line Protocol (CLP) module. It is made of a single combo module (no pointers to sub-sections) and must fit into 512 KB.

It is not required for LOM systems where it may be stored on the BIOS Flash device.

The module is pointed by the PCIe expansion/option ROM pointer at NVM word 0x05, expressed in 4 KB sector units. Whenever modifying this pointer in the NVM, it is required to issue a PCIe reset before any new access is performed to the Expansion ROM. Otherwise the X550 would continue to use the old pointer each time it internally maps accesses to the expansion ROM. Refer to [Section 3.4.3.1](#).

The first 330 words listed in [Table 6-7](#) (up to the *Reserved spare word*) are mapped at the end of the area allocated to the module (a trailer), though for the sake of the authentication, these words are mapped at the module's header, as listed in the table.

## 6.7 PHY Module

Refer to [Section 3.7.3.3](#) for the way this module is used by the X550.

The module is pointed by the PHY module pointer at NVM word address 0x4 (or word address 0x2004), expressed in 4 KB sector units. Before performing an auto-load, the PHY reads this pointer directly from the NVM.

The PHY module is composed of the following three sections as shown in [Figure 6-4](#):

- **Header** — Provides configuration information for the SPI interface and pointers to the Instruction RAM and Data RAM locations. (See [Table 6-10](#) for detailed description of the header content).
- **Instruction RAM** — This section of the image is loaded into the instructional SRAM (ISRAM).
- **Data RAM** — This section of the image is loaded into the data SRAM (DSRAM).

**Figure 6-4. PHY Module Map**

**Table 6-10. PHY Module Header**

| Byte Offset   | Description                                                                                                                                                                                               |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x00 – 0x7F   | Authentication Header.                                                                                                                                                                                    |
| 0x80 – 0x17F  | RSA Public Key — This field is skipped for the sake of SHA256 Hash computing.                                                                                                                             |
| 0x180 – 0x183 | RSA Exponent — This field is skipped for the sake of SHA256 Hash computing.                                                                                                                               |
| 0x184 – 0x283 | Encrypted SHA256 Hash — This field is skipped for the sake of SHA256 Hash computing.                                                                                                                      |
| 0x284 – 0x285 | X550 Blank NVM Device ID — A unique ND-provided device ID that identifies the X550 controller among other ND controllers. It must be set to 0x1562 in the X550.                                           |
| 0x286 – 0x289 | Max Module Area — It is the maximum flash area expressed in words that can be used by the module, starting from authentication header (included). It is set to 256 K words (i.e. 512 KB) for all modules. |
| 0x28A – 0x28D | Current Module Area — It is the flash area expressed in words that is currently used by the module, starting from authentication header (included).                                                       |

**Table 6-10. PHY Module Header (Continued)**

| Byte Offset   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x28E – 0x28F | Module Format Version + CRC8:<br>Bit[15] = CRC8 field is used. Set to 1b if a CRC8 is computed over the module, set to 0b otherwise.<br>Bits[14:8] = Module format version. Set to 0x02 if this currently defined format is used.<br>Bits[7:0] = CRC8 value computed over the parent module only, starting from authentication header (included) and including all other module's fields and segments - excluding all descendant modules and <i>RSA Public Key/RSA Exponent</i> fields.<br>CRC8 field is skipped for the sake of CRC8 computing (when bit 15 is set to 0b). |
| 0x290 – 0x291 | Code Revision:<br>Bits[15:8] = Major revision number.<br>Bits[7:0] = Minor revision number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 0x292 – 0x2FF | Reserved Spare Words — Must be set to zero.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| 0x315         | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 0x316         | Expected CRC16[7:0] <sup>1</sup>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 0x317         | Expected CRC16[15:8]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

1. Calculated from 0x300 to the end of the PHY code.

The PHY module is organized as follows, where offsets are expressed in bytes from the beginning of the module:

- 0x00000000 – 0x00000317: Header (see [Table 6-10](#)).
- 0x00000318 – 0x000004BF: Reset Vector (processor jumps here on reset).

This small assembly language routine sets up basic processor functions and loads the IRAM and DRAM memories. When memories are initialized, they jump to the start up code in the IRAM.

- 0x000004C0 – 0x000005BF: Register Provisioning Table.

One of the first things that's done at reset is to override the PIF registers with registers from these tables. A utility is available that manages this table called provision.

Defaults to PHY interrupts mask registers must always be provisioned here because they impact the PHY's operation with the MC before the operating system is up.

- 0x000005C0 – 0x000005FF: Version String (62 bytes), Firmware major/minor revision numbers (2 bytes).
- 0x00000600 – Current Module Area: IRAM/DRAM load tables and contents.

The boot code uses the load table and data in this region to initialize IRAM and DRAM.

## 6.7.1 Register Provisional Table

The PHY registers provisioning table consists of a variable number of change lists, the minimum number of change list is zero, and the maximum number is limited only by the size of the table, 256 bytes shared by both ports.

There is a master provisioning list that applies to both PHYs in addition to separate PHY specific changes lists (to reduce the table size).

Each change list consists of a 4-byte header and at least one change specification. The header consists of a one byte PHY identifier, a one byte MMD device address, and a two bytes count of change specifications to follow. Master provisioning is identified by a 0xFF PHY identifier.

Each change specification consists of a two byte register address within the MMD and a two byte value. Only fields marked with a PD Type in [Section 10.0](#) are affected.

The following content is expected in the provisioning area:

| Register | Value |
|----------|-------|
| 1E.D400  | 0x40  |
| 1E.D402  | 0x501 |
| 1E.FF00  | 0x1   |
| 1E.FF01  | 0x5   |

**NOTE:**      *This page intentionally left blank.*

## 7.0 Inline Functions

---

### 7.1 Receive Functionality

Packet reception consists of:

- Recognizing the presence of a packet on the wire ([Section 7.1.1](#))
- Performing address filtering ([Section 7.1.2](#))
- Optional IPsec decryption and authentication ([Section 7.13](#))
- Checksum off-loads ([Section 7.1.6](#))
- DMA queue assignment ([Section 7.1.3](#))
- Storing the packet in the receive data FIFO ([Section 7.6.3.1](#))
- Transferring the data to assigned receive queues in host memory ([Section 7.1.4](#))
- Optional Receive Side Coalescing ([Section 7.10](#))
- Updating the state of a receive descriptor ([Section 7.1.5](#)).

#### 7.1.1 MAC Layer - Receive

##### 7.1.1.1 Packet Acceptance Criteria

In addition to the filtering rules described in the next sections, a packet must also meet the following criteria to be accepted by the device:

1. Normally, only good packets are received (packets with none of the following errors: Under Size Error, Over Size Error, Packet Error, Length Error and CRC Error). However, if the *Store Bad Packets* bit is set (FCTRL.SBP), bad packets that don't pass the filter function are stored in host memory. Packet errors are indicated by error bits in the receive descriptor (RDESC.ERRORS). It is possible to receive all packets, regardless of whether they are bad, by setting the promiscuous enables bit and the *Store Bad Packets* bit. In this case, bad packets are queued according to the same rules as regular packets.
2. Min. Packet Size (Runt packets) — Rx packets, smaller than 48 bytes, cannot be posted to host memory regardless of save bad frame setting.
3. Max Packet Size — Any Rx packet posted from the MAC unit to the DMA unit cannot exceed 15.5 KB. Further restrictions per queue are described in [Section 7.1.4](#).
4. CRC errors before the Start Frame Delimiter (SFD) are ignored. All packets must have a valid SFD to be recognized by the device (even bad packets).

### 7.1.1.2 CRC Strip

The X550 potentially strips the L2 CRC on incoming packets.

CRC strip is enabled by the `HLREG0.RXCRCSTRP` bit. When set, CRC is stripped from all received packets.

The global CRC strip bit (`HLREG0.RXCRCSTRP`) must be set in the following cases where the packet changes before being handled to the driver:

- RSC is enabled in any queue.
- VLAN is hidden (`PFQDE.HIDE_VLAN = 1`) in any queue.
- E-tag is removed in any queue (`PFQDE.STRIP_TAG` is set)
- L2 tags are stripped from packets (`PFQDE.STRIP_TAG = 1`) in any queue.
- IPsec is enabled.
- Time stamp is added to the packets in any TC (any bit of `TSYNCRXCTL.TSIP_UT_EN` or `TSYNCRXCTL.TSIP_UP_EN` is set).
- Short received packets are padded (`RDRXCTL.PSP` is set).

## 7.1.2 Packet Filtering

A received packet goes through up to three stages of filtering as depicted in [Figure 7-1](#). The figure describes a switch-like structure that is used in virtualization mode to route packets between the network port (top of drawing) and one of many virtual ports (bottom of drawing), where each virtual port might be associated with a Virtual Machine (VM), a Virtual Machine Monitor (VMM), or the like. The three stages are:

1. **First stage — Admission Control:** Ensure that the packet should be received by the port. This is done by a set of L2 filters and is described in detail in this section.
2. **Second stage — Pooling:** This stage is specific to virtualization environments and defines the virtual ports (called pools in this document) that are the targets for the Rx packet. A packet can be associated with any number of ports/pools and the selection process is described in [Section 7.1.3.2](#). In non virtualization mode, this stage is skipped and all the queues used in the next stage are considered as part of the same default pool.

**Note:** A pool is equivalent to a VSI as defined in IEEE 802.1Qbg specification.

**Note:** FCoE packets are not expected in virtual machines, and thus bypasses the pooling mechanism.

3. **Third stage — Queueing:** A receive packet that successfully passed the Rx filters is associated with one of many receive descriptor queues as described in [Section 7.1.3](#).

**Figure 7-1. Stages in Packet Filtering - Virtualization Mode**

The receive packet filtering role is to determine which of the incoming packets are allowed to pass to the local machine and which of the incoming packets should be dropped since they are not targeted to the local machine. Received packets that are targeted for the local machine can be destined to the host, to a manageability controller, or to both. This section describes how host filtering is done, and the interaction with management filtering.

As depicted in [Figure 7-2](#), host filtering is done in two stages:

1. Packets are filtered by L2 filters (Ethernet MAC Address, unicast/multicast/broadcast). See [Section 7.1.2.1](#).
2. Packets are filtered by VLAN if a VLAN tag is present. See [Section 7.1.2.2](#).

A packet is not forwarded to the host if any of the following occurs:

- The packet does not pass L2 filters, as described in [Section 7.1.2.1](#).
- The packet does not pass VLAN filtering, as described in [Section 7.1.2.2](#).
- The packet passes manageability filtering and the manageability filters determine that the packet should not pass to the host (see MNGONLY register and [Section 11.3.5.2](#)).

Figure 7-2. Rx Filtering Flow Chart

### 7.1.2.1 L2 Filtering

A packet passes successfully through L2 Ethernet MAC Address filtering if any of the following conditions are met:

- **Unicast packet filtering** — Promiscuous unicast filtering is enabled ( $FCTRL.UPE = 1b$ ) or the packet passes unicast MAC filters (host).
- **Multicast packet filtering** — Promiscuous multicast filtering is enabled ( $FCTRL.MPE = 1b$ ) or the packet matches one of the multicast filters.
- **Broadcast packet filtering to host** — Promiscuous multicast filtering is enabled ( $FCTRL.MPE = 1b$ ) or Broadcast Accept Mode is enabled ( $FCTRL.BAM = 1b$ ).

#### 7.1.2.1.1 Unicast Filter

The Ethernet MAC Address is checked against the 128 host unicast addresses and 4 KB hash-based unicast address filters (if enabled). The host unicast addresses are controlled by the host interface. The destination address of an incoming packet must exactly match one of the pre-configured host address filters. These addresses can be unicast or multicast. Those filters are configured through Receive Address Low (RAL), Receive Address High (RAH), In addition, there are 4 KB unicast hash filters used for host defined by the PFUTA registers. The unicast hash filters are useful mainly for virtualization settings in those cases that more than 128 filters might be required.

Promiscuous Unicast — Receive all unicasts. Promiscuous unicast mode is usually used when the LAN device is used as a sniffer.

### 7.1.2.1.2 Multicast Filter (Partial)

The 12-bit portion of the incoming packet multicast address must be set in the multicast filter address table (*MTA*) to pass the partial multicast filter. The bits (out of 48 bits of the destination address) used to index the MTA table can be selected by the *MO* field in the MCSTCTRL register.

Promiscuous Multicast — Receive all multicasts. Promiscuous multicast mode is usually used when the LAN device is used as a sniffer.

## 7.1.2.2 VLAN Filtering

The X550 provides exact VLAN filtering as follows:

- Host VLAN filters are programmed by the VFTA[n] registers.
- A VLAN match might relate to the *DEI* bit in the VLAN header. It is enabled for host filtering only by the VLNCTRL.DEIEN while the expected value is defined by the VLNCTRL.DEI.

If double VLAN is enabled (see [Section 7.4.5](#)), filtering is done on the second (internal) VLAN tag. All the filtering functions of the X550 ignore the first (external) VLAN in this mode.

A receive packet that passes MAC Address filtering successfully is subjected to VLAN header filtering as illustrated in [Figure 7-3](#):

1. If the packet does not have a VLAN header, it passes to the next filtering stage.
2. Else, if VLAN filters are not enabled (VLNCTRL.VFE = 0b), the packet is forwarded to the next filtering stage.
3. Else, if the packet matches an enabled VLAN filter and DEI checking (if enabled), the packet is forwarded to the next filtering stage.
4. Otherwise, the packet is dropped.

Figure 7-3. VLAN Filtering

### 7.1.2.3 E-tag Filtering

If the PFVTCTL.POOLING\_MODE is E-tag (01b), special L2 filtering rules are applied to tagged packets.

- If the tag matches one of the RAH registers used for tag filtering (RAH.ADTYPE = 1), it is considered as a packet that passed L2.
- If the FCTRL.TPE bit is set (*Tag Promiscuous Enable*), all the tagged packets pass L2 filtering.
- Otherwise, packets with E-tag (if PFVTCTL.POOLING\_MODE is E-tag (01b)) are dropped.

**Note:** E-tag packets are not expected when double VLAN are use, thus PFVTCTL.POOLING\_MODE should be cleared if CTRL\_EXT.EXTENDED\_VLAN is set.

### 7.1.2.4 Manageability/Host Filtering

The host and manageability filtering process are mostly independent. Each entity defines which packet it should receive. The only exception is that the manageability filters can define a packet as exclusive and thus prevent it from reaching the host. See [Section 11.3.5.2](#) for details. [Figure 7-4](#) describes this flow.

**Figure 7-4. Manageability/Host Filtering**

## 7.1.3 Rx Queues Assignment

The following filters/mechanisms determine the destination of a received packet. These filters are described briefly while more detailed descriptions are provided in the following sections:

- **Virtualization** — In a virtual environment, DMA resources are shared between more than one software entity (operating system and/or device driver). This is done by allocating receive descriptor queues to virtual partitions (VMM, IOVM, VMs, or VFs). Allocating queues to virtual partitions is done in sets, each with the same number of queues, called queue pools, or pools. Virtualization assigns to each received packet one or more pool indices. Packets are routed to a pool based on their pool index and other considerations such as DCB and RSS. See [Section 7.1.3.2](#) for more on routing for virtualization.
- **DCB** — Data Center Bridging (DCB) provides QoS through priority queues, priority flow control, and congestion management. Packets are classified into one of several (up to eight) Traffic Classes (TCs). Each TC is associated with a single unique packet buffer. Packets that reside in a specific packet buffer are then routed to one of a set of Rx queues based on their TC value and other considerations such as RSS and virtualization. See [Section 7.6](#) for details on DCB.
  - DCB is enabled via the *DCB\_ENA* bit
- **Receive Side Scaling (RSS)** — RSS distributes packet processing between several processor cores by assigning packets into different descriptor queues. RSS assigns to each received packet an RSS index. Packets are routed to one queue from a set of Rx queues based on their RSS index and other considerations such as DCB and virtualization. See [Section 7.1.3.7](#) for details.
- **L2 Ethertype Filters** — These filters identify packets by their L2 Ethertype and assigns them to receive queues. Examples of possible uses are LLDP packets, and 802.1X packets. See [Section 7.1.3.3](#) for details. The X550 incorporates eight Ethertype filters.
- **FCoE Redirection Table** — FCoE packets that match the L2 filters might be directed to a single legacy Rx queue or multiple queues to ease multi-core processing. See [Section 7.1.3.4](#) for details. See also [Section 7.11.3.3](#) for Large FC receive and direct data placement. Up to 64 queues (any 64 of the 128 queues) can be allocated for FCoE traffic by the FCoE redirection table defined by FCRETA[n] registers.
- **Flow Director Filters** — These filters that provide up to additional 32 K filters. See [Section 7.1.3.6](#) for details.
- **TCP SYN Filters** — The X550 might route TCP packets with their SYN flag set into a separate queue. SYN packets are often used in SYN attacks to load the system with numerous requests for new connections. By filtering such packets to a separate queue, security software can monitor and act on SYN attacks. See [Section 7.1.3.5](#) for details.

A received packet is allocated to a queue based on the above criteria and the following order:

- Queue by L2 Ethertype filters (if match)
- Queue by FCoE redirection table (relevant for FCoE packets)
- Queue by SYN filter (if match)
- Queue by flow director filters
- Queue (in case of virtualization, within a pool) by DCB and/or RSS as described in [Section 7.1.3.1](#) and [Section 7.1.3.2](#).
- Send to queue zero.

### 7.1.3.1 Queuing in a Non-virtualized Environment

Table 7-1 lists the queuing schemes for packets that do not match any special filters (L2 Ethertype, FCoE redirection, SYN and flow director filters). Table 7-2 illustrates the queue indexing. Selecting a scheme is done via the *Multiple Receive Queues Enable (MRQE)* field in MRQC register.

**Table 7-1. Rx Queuing Schemes Supported (No Virtualization)**

| DCB | RSS | DCB/RSS Queues                                                     | Special Filters <sup>1</sup> |
|-----|-----|--------------------------------------------------------------------|------------------------------|
| No  | No  | 1 queue<br>Rx queue 0                                              | Supported                    |
| No  | Yes | 64 RSS queues                                                      | Supported                    |
| Yes | No  | 8 TCs x 1 queue<br>4 TCs x 1 queue<br>Assign Rx queue 0 of each TC | Supported                    |
| Yes | Yes | 8 TCs x 16 RSS<br>4 TCs x 32 RSS                                   | Supported                    |

1. Special filters include: L2 filters; FCoE redirection; SYN filter. When possible it is recommended to assign Rx queues not used by the DCB / RSS queues.

**Table 7-2. Queue Indexing Illustration in Non-virtualization Mode**

| MRQC.MRQE | Queue Index Bits | 6   | 5 | 4                | 3                | 2 | 1 | 0 |
|-----------|------------------|-----|---|------------------|------------------|---|---|---|
| 0000b     | Default only     | 0   |   |                  |                  |   |   |   |
| 0001b     | RSS              | RSS |   |                  |                  |   |   |   |
| 0101b     | DCB(4) + RSS     | TC  |   | RSS <sup>1</sup> |                  |   |   |   |
| 0011b     | DCB(4)           | TC  |   | 0                |                  |   |   |   |
| 0100b     | DCB(8) + RSS     | TC  |   |                  | RSS <sup>1</sup> |   |   |   |
| 0010b     | DCB(8)           | TC  |   |                  | 0                |   |   |   |

1. The number of bits used for each TC is set according to the RQTC.RQTCx fields

A received packet is assigned to a queue according to the ordering shown in Figure 7-5:

- **DCB and RSS filters** — Packets that do not meet any of the previous filtering conditions described in Section 7.1.3 are assigned to one of 128 queues as listed in Table 7-1. The following modes are supported:
  - **No DCB, No RSS** — Queue 0 is used for all packets.
  - **RSS only** — A set of 64 queues is allocated for RSS. The queue is identified through the RSS index. Note that it is possible to use a subset of these queues.
  - **DCB only** — A single queue is allocated per TC to a total of eight queues (if the number of TCs is eight), or to a total of four queues (if the number of TCs is four). The queue is identified through the TC index.
  - **DCB with RSS** — A packet is assigned to one of 128 queues (8 TCs x 16 RSS or 4 TCs x 32 RSS) through the DCB traffic class of the packet and the RSS index. The TC index is used as the MS bits of the Rx queue index, and the LS bits are defined by the RSS index. The number of queues used for each TC are set according to the RQTC.RQTCx fields

When operating in conjunction with DCB, the number of RSS queues can vary per DCB TC. Each TC can be configured to a different number of RSS queues (1/2/4/8/16/32 queues). The output of the RSS redirection table is masked accordingly to generate an RSS index of the right width. When configured to less than the maximum number of queues, the respective MS bits of the RSS index are set to zero. The number of RSS queues per TC is configured in the RQTC register.

- Example — Assume a 4 TCs x 32 RSS configuration and that the number of RSS queues for TC=3 is set to 4. The queue numbers for TC=3 are 64, 65, 66, and 67 (decimal).

Figure 7-5 depicts the flow of allocation of Rx queues by the various queue filters previously described:

**Figure 7-5. Rx Queuing Flow (Non-virtualized)**

### 7.1.3.2 Queuing in a Virtualized Environment

The 128 Rx queues are allocated to a pre-configured number of queue sets, called pools. In non-IOV mode, system software allocates the pools to the VMM or to VMs. In IOV mode, each pool may be associated with a VF.

Incoming packets are associated with pools based on their L2 characteristics as described in [Section 7.8.3](#). This section describes the following stage, where an Rx queue is assigned to each replication of the Rx packet as determined by its pools association.

[Table 7-3](#) lists the queuing schemes supported with virtualization. [Table 7-4](#) lists the queue indexing.

**Table 7-3. Rx Queuing Schemes Supported with Virtualization**

| DCB | RSS | DCB/RSS Queues                                                                              | Special Filters <sup>1</sup> |
|-----|-----|---------------------------------------------------------------------------------------------|------------------------------|
| No  | No  | 16 pools x 1 queue<br>32 pools x 1 queue<br>64 pools x 1 queue<br>- Rx queue 0 of each pool | Supported                    |
| No  | Yes | 32 pools x 4 RSS<br>64 pools x 2 RSS                                                        | Supported                    |
| Yes | No  | 16 pools x 8 TCs<br>32 pools x 4 TCs                                                        | Supported                    |
| Yes | Yes | N/A                                                                                         | N/A                          |

1. Special filters include: L2 filters; FCoE redirection; SYN filter. When possible it is recommended to assign Rx queues not used by the DCB / RSS queues.

**Table 7-4. Queue Indexing Illustration in Virtualization Mode**

| MRQC.MRQE   | Queue Index Bits         | 6             | 5 | 4 | 3 | 2 | 1 | 0   |
|-------------|--------------------------|---------------|---|---|---|---|---|-----|
| 1000b       |                          | Pool Index    |   |   |   |   |   | 0   |
| 1011b       | VT(64) + RSS             | Pool Index    |   |   |   |   |   | RSS |
| 1001b/1111b | VT(64) + RSS + Mega Pool | Pool Index    |   |   |   |   |   | RSS |
| 1010b       | VT(32) + RSS             | Pool Index    |   |   |   |   |   | RSS |
| N/A         | VT(16) + RSS             | Not Supported |   |   |   |   |   |     |
| 1101b       | VT(32) + DCB(4)          | Pool Index    |   |   |   |   |   | TC  |
| 1100b       | VT(16) + DCB(8)          | Pool Index    |   |   |   |   |   | TC  |
|             |                          |               |   |   |   |   |   |     |

1. When *MRQC.MRQE* = 0xF, VF index for pools 0-59, part of RSS for pool 60, 62 and pools 61 and 63 are disabled. When *MRQC.MRQE* = 0x0, VF index for pools 0-61, part of RSS for pool 62 and pool 63 is disabled.

Selecting a scheme is done in the following manner:

- Non-IOV mode
  - Select one of the above schemes via the *Multiple Receive Queues Enable* field in the MRQC register.
- IOV mode
  - Determine the number of pools: the number must support the value configured by the operating system in the PCIe *NumVFs* field (see [Section 9.2.4.4.5](#)). Therefore, the number of pools is min. of {16, 32, 64} that is still >= NumVFs.
  - Determine DCB mode via the *DCB\_ENA bit* in MTQC register.

A received packet is assigned to an absolute queue index according to the ordering shown in Figure 7-6). It is software responsibility to define a queue that belongs to the matched pool:

- DCB and RSS filters — The supported modes are listed in Table 7-3 and detailed as follows. The associated queue indexes are listed in Table 7-4.
  - **No DCB, No RSS** — A single queue is used as default queue of the pool with either 16, 32, or 64 pools enabled. In a 64 pools setting, queues '2xN'...'2xN+1' are allocated to pool 'N'; In a 32 pools setting, queues '4xN'...'4xN+3' are allocated to pool 'N'. The queues not used as default may be directed to by other filters.
  - **RSS only** — All 128 queues are allocated to pools. Configurations supported:
    - 32 pools with 4 RSS queues each
    - 64 pools with 2 RSS queues each.
    - 63 pools. The first 62 with 2 queues each and the last one with 4 RSS queues. In this mode the last pool is 62 and pool 63 is disabled.
    - 62 pools. The first 60 with 2 queues each and the last two with 4 RSS queues each. In this mode the last two pools are 60 and 62 and pools 61/63 are disabled.
- Note:** It is possible to use a subset of the RSS queues in each pool. The LS bits of the queue indexes are defined by the RSS index, and the pool index is used as the MS bits. See description below.
- Note:** In the 62 and 63 pools modes, the pools with 4 queues should be assigned to the PF and can not be assigned to a VF.
- **DCB only** — All 128 queues are allocated to pools. Two configurations are supported: 16 pools with 8 TCs each or 32 pools with 4 TCs each. The LS bits of the queue indexes are defined by the TC index, and the pool index is used as the MS bits.
- **DCB and RSS** — All 128 queues are allocated to pools. One configuration is supported: 16 pools with 4 TCs each TC with 2 RSS queues. The LS bit of the queue indexes is defined by the RSS index, the next 2 bits of the queue indexes are defined by the TC index, and the pool index is used as the MS bits.

When operating in conjunction with RSS, the number of RSS queues can vary per pool as defined by the PSRTYPE[n].RQPL. Each pool can be configured to a different number of RSS queues (1/2/4- queues) up to the maximum possible queues in the selected mode of operation. The output of the RSS redirection table is masked accordingly to generate an RSS index of the right width. When configured to less than the maximum number of queues, the respective MS bits of the RSS index are set to zero.

**Figure 7-6. Rx Queuing Flow (Virtualization Case)**

### 7.1.3.3 L2 Ethertype Filters

These filters identify packets by their L2 Ethertype, 802.1Q user priority and optionally assign them to a receive queue. The following possible usages have been identified at this time:

- DCB LLDP packets — Identifies DCB control packets
- IEEE 802.1X packets — Extensible Authentication Protocol (EAPOL) over LAN
- Time sync packets (such as IEEE 1588) — Identifies Sync or Delay\_Req packets
- FCoE packets (possibly two UP values)
- The L2 type filters should not be set to IP packet type as this might cause unexpected results

The X550 incorporates eight Ethertype filters defined by a set of two registers per filter: ETQF[n] and ETQS[n].

The L2 packet type is defined by comparing the *EtherType* field in the Rx packet with the ETQF[n].*ETYPE* (regardless of the pool and UP matching). The *Packet Type* field in the Rx descriptor captures the filter number that matched with the L2 Ethertype. See [Section 7.1.5.2.2](#) for a description of the *Packet Type* field.

The following flow is used by the Ethertype filters:

1. If the `ETQF.FILTER_ENABLE` bit is cleared, the filter is disabled and the following steps are ignored.
2. Receive packet matches any ETQF filters if the *EtherType* field in the packet matches the *ETYPE* field of the filter. Note that the following steps are ignored if the packet does not match the ETQF filters.  
**Note:** Ethertype Filters should not be configured in a way that may cause a packet to match multiple filters.
3. Packets that match any ETQF filters are candidate for the host. If the packet also matches the manageability filters, it is directed to the host as well regardless of the `MNGONLY` register setting.
4. If the `ETQF.FCOE` field is set, the packet is identified as an FCoE packet.
5. If the `ETQF.IEEE_1588_TIME_STAMP` field is set, the packet is identified as an IEEE 1588 packet.
6. If the `ETQS.QUEUE_ENABLE` bit is cleared, the filter completed its action on the packet. Else, the filter is also used for queuing purposes as described in the sections that follow.
7. If the `ETQF.POOL_ENABLE` field is set, the *Pool* field of the filter determines the target pool for the packet. The packet can still be mirrored to other pools as described in [Section 7.8.3](#). See the sections that follow for more details on the use of the *Pool* field.
8. The `ETQS.RX_QUEUE` field determines the destination queue for the packet. In case of a mirrored packet, only the copy of the packet that is targeted to the pool defined by the *Pool* field in the *ETQF* register is routed according to the *Rx Queue* field.

Setting the `ETQF[n]` registers is described as follows:

- The `FILTER_ENABLE` bit enables identification of Rx packets by Ethertype according to this filter. If this bit is cleared, the filter is ignored.
- The `ETYPE` field contains the 16-bit Ethertype compared against all L2 type fields in the Rx packet.
- The `FCOE` bit indicates that the Ethertype defined in the *EType* field is an FCoE EType. Packets that match this filter are identified as FCoE packets.
- The `IEEE_1588_TIME_STAMP` bit indicates that the Ethertype defined in the *EType* field is identified as IEEE 1588 EType. Packets that match this filter are time stamped according to the IEEE 1588 specification.
- The *Pool* field defines the target pool for a packet that matches the filter.
  - It applies only in virtualization modes. The pool index is meaningful only if the `POOL_ENABLE` bit is set.
  - If the `POOL_ENABLE` bit is set, the `QUEUE_ENABLE` bit in the `ETQS` register must be set as well. In this case, the `RX_QUEUE` field in the `ETQS` must be part of the pool number defined in the `ETQF`.

Setting the `ETQS[n]` registers is described as follows:

- The `QUEUE_ENABLE` bit enables routing of the Rx packet that match the filter to Rx queue as defined by the `RX_QUEUE` field.
- The `RX_QUEUE` field contains the destination queue (one of 128 queues) for the packet.

Special considerations for virtualization modes:

- Packets that match an Ethertype filter are diverted from their original pool (as defined by the VLAN and Ethernet MAC Address filters) to the pool defined in the *Pool* field in the `ETQF` registers.
- The same applies for multicast packets. A single copy is posted to the pool defined by the filter.

- Mirroring rules
  - A packet sent to a pool by an ETQF filter, is still candidate to mirroring using the standard mirroring rules.
  - The Ethertype filter does not take part in the decision on the destination of the mirrored packet.

### 7.1.3.4 FCoE Redirection Table

The FCoE redirection table is a mechanism to distribute received FCoE packets into several descriptor queues. Software might assign each queue to a different processor, sharing the load of packet processing among multiple processors. The FCoE redirection table assigns Rx queues to packets that are identified as FCoE in the ETQF[n] registers but not assigned to queues in the ETQS[n] registers.

Figure 7-7 illustrates the computing of the assigned Rx queue index by the FCoE redirection table.

- The receive packet is parsed and the OX\_ID is extracted for the filtering to Rx LAN queue (named as EX\_ID).
- The six LS bits of the OX\_ID are used as an address to the redirection table (FCRETA[n] register index).
- The FCoE redirection table is enabled by the FCRECTL.ENA bit. If enabled, the content of the selected FCRETA[n] register is the assigned Rx queue index.
- FCoE Packets with SNAP header are routed according to FCRETA[0].TABLE\_ENTRY.
- If the FCoE redirection table is disabled, FCoE packets are assigned to queue 0.

**Figure 7-7. FCoE Redirection Table**

### 7.1.3.5 SYN Packet Filters

The X550 might route TCP packets whose SYN flag is set into a separate queue. SYN packets are used in SYN attacks to load the system with numerous requests for new connections. By filtering such packets to a separate queue, security software can monitor and act on SYN attacks.

The following rules apply:

- A single SYN filter is provided.

The SYN filter is configured via the SYNQF register as follows:

- The *QUEUE\_ENABLE* bit enables SYN filtering capability.
- The *RX\_QUEUE* field contains the destination queue for the packet (one of 128 queues). In case of mirroring (in virtualization mode), only the original copy of the packet is routed according to this filter.

### 7.1.3.6 Flow Director Filters

The flow director filters identify specific flows or sets of flows and routes them to specific queues. The flow director filters are programmed by FDIRCTRL and all other FDIR registers. The X550 shares the Rx packet buffer for the storage of these filters.

The X550 supports three different modes of flow director (set in the FDIRCTRL.FILTERMODE field - [Section 8.2.2.15.1](#)):

- IP filtering (000b)
- MAC, VLAN filtering (001b)
- Cloud: NVGRE or VXLAN filtering (010b)

[Table 7-5](#) describes the packets that are candidate to compared to the flow director filters according to the different modes:

**Table 7-5. Candidate for Flow Director per Mode**

| Mode                            | IP packets<br>TCP/UDP/SCTP<br>(Not Tunneled) | Non IP Packets | NVGRE Packets                        | VXLAN packets                        | Other IP packets<br>or Fragmented IP |
|---------------------------------|----------------------------------------------|----------------|--------------------------------------|--------------------------------------|--------------------------------------|
| 00 - IP<br>(L4 fields unmasked) | Candidate                                    | Not Candidate  | Candidate<br>(inner IP) <sup>1</sup> | Candidate<br>(inner IP) <sup>1</sup> | Not Candidate                        |
| 00 - IP<br>(L4 fields masked)   | Candidate                                    | Not Candidate  | Candidate<br>(inner IP) <sup>2</sup> | Candidate<br>(inner IP) <sup>2</sup> | Candidate <sup>2/3</sup>             |
| 01 - MAC VLAN                   | Candidate                                    | Candidate      | Candidate                            | Candidate                            | Candidate                            |
| 10 - Cloud                      | Not Candidate                                | Not Candidate  | Candidate                            | Candidate                            | Not Candidate                        |

1. Only if a known L4 header is present (TCP/UDP/SCTP).

2. VXLAN and NVGRE packets without inner IP header (e.g. tunneled ARP) are not candidate in IP mode.

3. IP in IP packets are not candidate in IP mode.

Basic rules for the flow director filters are:

In VT mode, the *Pool* field in FDIRCMD must be valid. If the packet is replicated, only the copy that goes to the pool that matches the *Pool* field is impacted by the filter. The flow director filters cover the following fields:

**Table 7-6. Lookup Fields for Flow Director per Mode**

| Mode          | Lookup Fields                                                                                                                                                                                                                                                                                                                                                             |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 00 - IP       | <ul style="list-style-type: none"> <li>VLAN header</li> <li>Source IP and destination IP Addresses</li> <li>Source port and destination port numbers</li> <li>IPv4 / IPv6<sup>1</sup> and UDP / TCP or SCTP protocol match</li> <li>Flexible 2-byte tuple anywhere in the first 64 bytes of the packet</li> <li>Target pool number (relevant only for VT mode)</li> </ul> |
| 01 - MAC VLAN | <ul style="list-style-type: none"> <li>MAC</li> <li>VLAN</li> <li>Flexible 2-byte tuple anywhere in the first 64 bytes of the packet</li> <li>Target pool number (relevant only for VT mode)</li> </ul>                                                                                                                                                                   |
| 10 - Cloud    | <ul style="list-style-type: none"> <li>Tunnel type - NVGRE or VXLAN</li> <li>TNI (NVGRE) / VNI (VXLAN)</li> <li>Inner MAC</li> <li>Inner VLAN</li> <li>Flexible 2-byte tuple anywhere in the first 64 bytes of the packet</li> <li>Target pool number (relevant only for VT mode)</li> </ul>                                                                              |

1. IPv6 extended headers are parsed by the X550, enabling TCP layer header recognition. Still the IPv6 extended header fields are not taken into account for the queue classification by Flow Director filter. This rule do not apply for security headers and fragmentation header. Packets with fragmentation header miss this filter. Packets with security extended headers are parsed only up to these headers and therefore can match only filters that do not require fields from the L4 protocol.

The X550 supports two types of filtering modes (static setting by the `FDIRCTRL.PERFECT_MATCH` bit):

- **Perfect Match Filters** — The hardware checks a match between the masked fields of the received packets and the programmed filters. Masked fields should be programmed as zeros in the filter context. The X550 supports up to 8 K - 1 perfect match filters.
- **Signature Filters** — The hardware checks a match between a hash-based signature of the masked fields of the received packet. The X550 supports up to 32 K - 1 signature filters. This mode can be used only when the filtering mode is IPMODE (`FDIRCTRL.FILTERMODE` = 000b).

**Note:** The *Perfect Match* fields and *Signature* field are denoted as *Flow ID* fields.

The X550 supports masking / range for the previously described fields. These masks are defined globally for all filters in the `FDIR...M` registers.

- The following fields can be masked per bit enabling power of two ranges up to complete enable / disable of the fields: IPv4 addresses and L4 port numbers.
- The following fields can be masked per byte enabling lower granularity ranges up to complete enable / disable of the fields: IPv6 addresses; Inner MAC; Outer MAC; *TNI/VNI* field.

**Note:** In perfect match filters the destination IPv6 address can only be compared as a whole (with no range support) to the *IP6AT* filters. A match to any of the *IP6AT* filter is considered as an IPv6 destination match.

- The following fields can be either enabled or disabled completely for the match functionality: VLAN ID tag; Outer VLAN Priority + *DEI* bit (the user priority is taken from the outermost tag with *UP* bits if an inner VLAN exists; otherwise it is ignored. Inner or outer VLAN tag; Flexible 2-byte tuple and target pool. Target pool can be enabled by software only when VT is enabled as well.

Flow director filters have the following functionality in virtualization mode:

- Flow director filters are programmed by the registers in the PF described in [Section 7.1.3.6.13](#) and [Section 7.1.3.6.14](#).
- Flow director filters can be utilized in virtualization mode to filter on MAC-VLAN by setting `FDIRCTRL.FILTERMODE = MACVLANMODE` (001b). `MACVLANMODE` is only used in flow director perfect match mode.

### 7.1.3.6.1 Flow Director Filters Actions

Flow director filters might have one of the following actions programmed per filter in the `FDIRCMD` register:

- Drop packet or pass to host as defined by the *Drop* bit.
  - Matched packets to a flow director filter is directed to the assigned Rx queue only if the packet does not match the L2 filters for queue assignment nor the SYN filter for queue assignment.
  - Packets that match a filter are directed to the Rx queue defined in the filter context as programmed by the `FDIRCMD.RX_QUEUE`. The `RX_QUEUE` field is an absolute receive queue index. In a non-VT setting, it can be programmed to any value. In VT mode, the software should set the `RX_QUEUE` to an index that belongs to the matched pool.
  - Packets that match drop filters are directed to the Rx queue defined per all filters in the `FDIRCTRL.DROP_QUEUE`. The X550 drops these packets if software does not enable the specific Rx queue.

### 7.1.3.6.2 Flow Director Default Action

A default drop action may be applied by the flow director for packets that are candidate to flow director as defined in [Table 7-5](#). If the `FDIRCTRL.DROP_NO_MATCH` bit is set, any packet candidate for flow director that does not match any of the filters is sent to the queue defined in the `FDIRCTRL.DROP_QUEUE` field.

### 7.1.3.6.3 Flow Director Filters Status Reporting

Shared status indications for all packets:

- The X550 increments the `FDIRMATCH` counter for packets that match a flow director filter. It also increments the `FDIRMISS` counter for packets that do not match any flow director filter.
- The *Flow Director Filter Match (FLM)* bit in the *Extended Status* field of the Rx descriptor is set for packets that match a flow director filter.
- The flow ID parameters are reported in the *Flow Director Filter ID* field in the Rx descriptor if enabled by the `FDIRCTRL.REPORT_STATUS`. When the *Report-Status* bit is set, the `RXCSUM.PCSD` bit should be set as well. This field is indicated for all packets that match or do not match the flow director filters.
  - For packets that do not match a flow director filter, if the `FDIRCTRL.REPORT_STATUS_ALWAYS` is set, the *Flow Director Filter ID* field can be used by software for future programming of a matched filter, otherwise, the RSS hash value is reported. [Table 7-7](#) describes the value of the `RSS_TYPE` field in the receive descriptor in the different cases.

**Table 7-7. RSS Type Values According to Flow Director Match**

| <i>REPORT_STATUS</i><br>(FDIRCTRL[5]) | <i>REPORT_STATUS_ALWAYS</i><br>(FDIRCTRL[7]) | Packet matches a Flow<br>Director Entry | RSS Type Field Value  |
|---------------------------------------|----------------------------------------------|-----------------------------------------|-----------------------|
| 0                                     | 0                                            | X                                       | RSS Type              |
| 1                                     | 0                                            | 0                                       | RSS Type              |
| 1                                     | 0                                            | 1                                       | 0xF                   |
| 0                                     | 1                                            | X                                       | illegal configuration |
| 1                                     | 1                                            | X                                       | 0xF                   |

For packets that match a flow director filter, the *Flow Director Filter ID* field can be used by software to identify the flow of the Rx packet. Too long linked list exception (linked list and too long terms are illustrated in [Figure 7-8](#)):

- The maximum recommended linked list length is programmed in the *FDIRCTRL.MAX\_LENGTH* field
- The length exception is reported in the *FDIRERR* field in the Rx descriptor
- Packets that do not match any flow director filter, reports this exception if the length of the existing linked list is above the maximum recommended length. Software can use it to avoid further programming of additional filters to this linked list before other filters are removed.
- Packets that match a pass filter report this exception if the distance of the matched filter from the beginning of the linked list is higher than the above recommended length.
- Packets that match a drop filter are posted to the Rx queue programmed in the filter context instead of the global *FDIRCTRL.DROP\_QUEUE*. The drop exception is reported in addition to the length exception (in the same field in the Rx descriptor).

Collision exception:

- Packets that matches a collided filter report this exception in the *FDIRERR* field in the Rx descriptor.
- Collision events for signature-based filters should be rare. Still it might happen because multiple flows can have the same hash and signature values. Software might leave the setting as is while the collided flows are handled according to the actions of the first programmed flow. Only one flow (out of the collided ones) might remain in the flow director filters. To clear the collision indication in the programmed filter, software should remove the filter and then re-program it once again.
- Collision events for a perfect match filter should never happen. A collision error might indicate a programming fault that software might decide to fix.

#### 7.1.3.6.4 Flow Director Filters Block Diagram

[Figure 7-8](#) shows a block diagram of the flow director filters. Received flows are identified to buckets by a hash function on the relevant tuples as defined by the *FDIR...M* registers. Each bucket is organized in a linked list indicated by the hash lookup table. Buckets can have a variable length while the last filter in each bucket is indicated as a last. There is no upper limit for a linked list length during programming. However, a received packet that matches a filter that exceeds the *FDIRCTRL.MAX\_LENGTH* are reported to software (see [Section 7.1.3.6.6](#)).

Figure 7-8. Flow Director Filters Block Diagram

### 7.1.3.6.5 Rx Packet Buffer Allocation

Flow director filters can consume zero space (when disabled) up to ~256 KB of memory. As shown in Figure 7-8, flow director filters share the same memory with the Rx packet buffer. By setting the *PBALLOC* field in the *FDIRCTRL* register, the software can enable and allocate memory for the flow director filters. The memory allocated to received traffic is the remaining part of the Rx packet buffer.

Table 7-8. Rx Packet Buffer Allocation

| PBALLOC (2)                     | Effective Rx Packet Buffer Size (see following note) | Flow Director Filters Memory | Supported Flow Director Filters |             |                |             |
|---------------------------------|------------------------------------------------------|------------------------------|---------------------------------|-------------|----------------|-------------|
|                                 |                                                      |                              | Signature                       |             | Perfect Match  |             |
|                                 |                                                      |                              | Filters                         | Bucket Hash | Filters        | Bucket Hash |
| 00<br>Flow Director is disabled | 384 KB                                               | 0                            | 0                               | N/A         | 0              | N/A         |
| 01                              | 320 KB                                               | 64 KB                        | 8 K -1 filters                  | 13 bit      | 2 K -1 filters | 11 bit      |
| 10                              | 256 KB                                               | 128 KB                       | 16 K -1 filters                 | 14 bit      | 4 K -1 filters | 12 bit      |
| 11                              | 128 KB                                               | 256 KB                       | 32 K -1 filters                 | 15 bit      | 8 K -1 filters | 13 bit      |

**Notes:**

- It is the user's responsibility to ensure that sufficient buffer space is left for reception of traffic. The required buffer space for receive traffic depends on the number of traffic classes, and flow control upper and lower threshold values. If flow director is enabled (*PBALLOC* > 0), software should set the *RXPBSIZE[n]* registers according to the total remaining part of the Rx packet buffer for reception of traffic.
- When allocating 256 KB to the Flow Director table, it is likely that the 128 KB packet buffer left is too small to permit operating the port in DCB enabled mode.
- Refer to [Section 3.7.4.3.2](#) through [Section 3.7.4.3.5](#) for recommended setting of the Rx packet buffer sizes and flow control thresholds.

### 7.1.3.6.6 Flow Director Filtering Reception Flow

- Rx packet is digested by the filter unit which parse the packet extracting the relevant tuples for the filtering functionality.
- The X550 calculates a 15-bit hash value out of the masked tuples (logic mask of the tuples and the relevant mask registers) using the hash function described in [Section 7.1.3.6.16](#).
- The address in the hash lookup table points to the selected linked list of flow director filters.
- The X550 checks the *Bucket Valid* flag. If it is inactive, the packet does not match any filter. Otherwise, *Bucket Valid* flag is active, proceed for the next steps.
- The X550 checks the linked list until it reaches the last filter in the linked list or until a matched filter is found.
- Case 1: Matched filter is found:
  - Increment the FDIRMATCH statistic counter.
  - Process the filter's actions (queue assignment) according to queue assignment priority. Meaning, the actions defined in this filter takes place only if the packet did not match any L2 filter or SYN filter that assigns an Rx queue to the packet.
  - Rx queue assignment according to the filter context takes place if *QUEUE\_EN* is set.
  - If the *DROP* bit is set in the filter context, the packet is sent to the queue pointed by the *FDIRCTRL.DROP\_QUEUE* field.
  - Post the packet to host including the flow director filter match indications as described in [Section 7.1.3.6.3](#).
- Case 2: Matched filter is not found:
  - Increment the FDIRMISS statistic counter.
  - Post the packet to host including the flow director filter miss indications as described in [Section 7.1.3.6.3](#).

### 7.1.3.6.7 Add Filter Flow

The software programs the filters parameters in the registers described in [Section 7.1.3.6.13](#) and [Section 7.1.3.6.14](#) while keeping the `FDIRCMD.FILTER_UPDATE` bit inactive. As a result, the X550 checks the bucket valid indication in the hash lookup table (that matches the `FDIRHASH.HASH`) for the presence of an existing linked list. Following are the two programming flows for the case a link list exists or for the case a new list is required.

- Case 1: Add a filter to existing linked list:

The X550 checks the linked list until it reaches the last filter in the list or until a matched filter is found. The following cases may occur:

- Matched filter is found (equal flow ID) with the same action parameters — The programming is discarded silently. This is a successful case since the programmed flow is treated as requested.
- Matched filter is found (equal flow ID) with different action parameters — The X550 keeps the old setting of the filter while setting the *Collision* flag in the filter context (see [Section 7.1.3.6.3](#) for software handling of collision during packet reception).
- Matched filter is found (equal flow ID) with different action parameters and the *Collision* flag is already set — The programming is discarded silently. Software gets the same indications as the previous case.
- Matched filter is not found (no collision) — The X550 checks for a free space in the flow director filters table.
- No space case — Discard programming; increment the *FADD* counter in the `FDIRFSTAT` register and assert the flow director interrupt. Following this interrupt software should read the `FDIRFSTAT` register and `FDIRFREE.FREE` field, for checking the interrupt cause.
- Free space is found — Good programming case: Add the new filter at the end of the linked list while indicating it as the last one. Program the *Next Filter PTR* field and then clear the *Last* flag in the filter that was previously the last one.

- Case 2: Create a new linked list:

The X550 looks for an empty space in the flow director filters table:

- Handle no empty space the same as in Case 1.
- Good programming case: Add the new filter while indicating it as the last one in the linked list. Then, program the hash lookup table entry by setting the *Valid* flag and the *First Filter PTR* pointing to the new programmed filter.

Additional successful add flow indications:

- Increment the *ADD* statistic counter in the `FDIRUSTAT` register.
- Reduce the *FREE* counter in the `FDIRFREE` register, and then indicate the number of free filters. If the *FREE* counter crosses the `FULL_THRESH` value in the `FDIRCTRL` register, assert the flow director filter interrupt. Following this interrupt software should read the `FDIRFSTAT` register and `FDIRFREE.FREE` field, for checking the interrupt cause.
- Compare the length of the new linked list with *MAXLEN* in the `FDIRLEN` register. If the new linked list is longer than *MAXLEN*, update the `FDIRLEN` by the new flow.

### 7.1.3.6.8 Update Filter Flow

In some applications, it is useful to update the filter parameters, such as the destination Rx queue. Programming filter parameters is described in [Section 7.1.3.6.7](#).

Setting the *FILTER\_UPDATE* bit in the *FDIRCMD* register has the following result:

- Case 1: Matched filter does not exist in the filter table — Setting the *FILTER\_UPDATE* bit has no impact and the command is treated as add filter.
- Case 2: Matched filter already exists in the filter table — Setting the *FILTER\_UPDATE* bit enables filter parameter's update while keeping the collision indication as is.

When updating an existing filter the software device driver should program the same filter (i.e. the same *FDIRHASH.HASH* and the same *FDIRHASH.SIGNATURE\_SW\_INDEX*) while keeping the *FDIRCMD.FILTER\_UPDATE* = 1

### 7.1.3.6.9 Remove Filter Flow

Software programs the filter Hash and Signature/Software-Index in the *FDIRHASH* register. It then should set the *FDIRCMD.CMD* field to *Remove Flow*. Software might use a single 64-bit access to the two registers for atomic operation. As a result, the X550 follows these steps:

1. Check if such a filter exists in the flow director filters table.
2. If there is no flow, increment the *FREMOVE* counter in the *FDIRFSTAT* register and skip the next steps.
3. If the requested filter is the only filter in the linked list, invalidate its entry in the hash lookup table by clearing the *Valid* bit.
4. Else, if the requested filter is the last filter in the linked list, invalidate the entry by setting the *Last* flag in the previous filter in the linked list.
5. Else, invalidate its entry by programming the *Next Filter PTR* in the previous filter in the linked list, pointing it to the filter that was linked to the removed filter.

Additional indications for successful filter removal:

1. Increment the remove statistic counter in the *FDIRUSTAT* register.
2. Increment the *FREE* counter in the *FDIRFREE* register.

### 7.1.3.6.10 Remove All Flow Director Filters

In some cases there is a need to clear the entire flow director table. It might be useful in some applications that might cause the flow director table becoming too occupied. Then, software might clear the entire table enabling its re-programming with new active flows.

Following are steps required to clear the flow director table:

- Poll the *FDIRCMD.CMD* until it is zero indicating any previous pending commands to the flow director table is completed (at worst case the *FDIRCMD.CMD* should be found cleared on the second read cycle). Note that software must not initiate any additional commands (add/remove/query) before this step starts and until this flow completes.
- Clear the *FDIRFREE* register (set *FREE* field to zero).
- Set *FDIRCMD.CLEARHT* to 1b and then clear it back to 0b.
- Clear the *FDIRHASH* register to zero.

- Re-write FDIRCTRL by its previous value while clearing the *INIT\_DONE* flag.
- Poll the *INIT\_DONE* flag until it is set to 1b by hardware.
- Clear the following statistic registers: FDIRUSTAT, FDIRFSTAT, FDIRMATCH, FDIRMISS, FDIRLEN (note that some of these registers are read clear and some are read write).

### 7.1.3.6.11 Flow Director Filters Initializing Flow

Following a device reset, the flow director is enabled by programming the FDIRCTRL register, as follows:

- Set *PBALLOC* to non-zero value according to the required buffer allocation to reception and flow director filter (see [Section 7.1.3.6.5](#)). All other fields in the register should be valid as well (according to required setting), as the FDIRCTRL register is expected to be programmed by a single cycle.
- Poll the *INIT\_DONE* flag until it is set to 1b by hardware (expected initialization flow should take about 55  $\mu$ s at 10 Gb/s and 550  $\mu$ s at 1 Gb/s).

**Note:** The value of the FDIRCTRL.*PERFECT\_MATCH* and FDIRCTRL.*FILTERMODE* should be modified only when no filters are set (at init time).

### 7.1.3.6.12 Query Filter Flow

Software might query specific filter settings and bucket length using the Query command.

- Program the filter *HASH* and *SIGNATURE\_SW\_INDEX* in the FDIRHASH register, and set the *CMD* field in the FDIRCMD register to 11b (Query Command). A single 64-bit access can be used for this step.
- As a result, the X550 provides the query result in the FDIRHASH, FDIRCMD and FDIRLEN registers (described in the sections as follows).
- Hardware indicates query completion by clearing the FDIRCMD.*CMD* field. The following table lists the query result.

| Query Outcome                          | FDIRHASH -> Bucket Valid | FDIRCMD -> Filter Valid | FDIRLEN -> Bucket Length            | FDIRCMD -> Filter ID Fields | FDIRCMD -> Filter Action         |
|----------------------------------------|--------------------------|-------------------------|-------------------------------------|-----------------------------|----------------------------------|
| Empty Bucket                           | 0                        | 0                       | N/A                                 | N/A                         | N/A                              |
| Valid Bucket, Matched Filter Not Found | 1                        | 0                       | Bucket linked list length           | N/A                         | N/A                              |
| Found Signature Filter                 | 1                        | 1                       | Filter index within the linked list | 0                           | Filter's parameters <sup>1</sup> |
| Found Perfect Match Filter             | 1                        | 1                       | Filter index within the linked list | Filter's parameters         | Filter's parameters              |

1. The pool parameter is not returned as part of the filter action in signature mode.

### 7.1.3.6.13 Signature Filter Registers

The signature flow director filter is programmed by setting the FDIRHASH and FDIRCMD registers. These registers are located in consecutive 8-byte aligned addresses. Software should use a 64-bit register to set these two registers in a single atomic operation. [Table 7-9](#) lists the recommended setting.

**Table 7-9. Signature Match Filter Parameters**

| Filter Bucket Parameters — FDIRHASH                                                                                   |                                                                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Hash                                                                                                                  | 15-bit hash function used to define a bucket of filters. This parameter is part of the flow director filter ID that can be reported in the Rx descriptor. It is shared for signature and perfect match filters. |
| Valid                                                                                                                 | Should be set to 1b. It is shared for signature and perfect match filters.                                                                                                                                      |
| Flow ID — FDIRHASH                                                                                                    |                                                                                                                                                                                                                 |
| Signature                                                                                                             | 15-bit hash function used as the flow matching field. This parameter is also part of the flow director filter ID that can be reported in the Rx descriptor.                                                     |
| FDIRCMD — Programming Command and Filter action — See <a href="#">Section 8.2.2.15.8</a> for all fields descriptions. |                                                                                                                                                                                                                 |

### 7.1.3.6.14 Perfect Match Filter Registers

Perfect match filters are programmed by the following registers: FDIRSIPv6[n], FDIRVLAN, FDIRPORT, FDIRIPDA, FDIRIPSA, FDIRHASH, FDIRCMD. Setting the FDIRCMD register, generates the actual programming of the filter. Therefore, write access to this register must be the last cycle after all other registers contain a valid content. [Table 7-10](#) lists the recommended setting.

**Note:** Software filter programming must be an atomic operation. In a multi-core environment, software must ensure that all registers are programmed in a sequence with no possible interference by other cores.

**Table 7-10. Perfect Match Filter Parameters**

| Filter Bucket Parameters and Software Index — FDIRHASH |                                                                                                                                                                                                              |                                                                           |                                         |
|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------|-----------------------------------------|
| Hash                                                   | See <a href="#">Section 7.1.3.6.13</a> .                                                                                                                                                                     |                                                                           |                                         |
| Valid                                                  | See <a href="#">Section 7.1.3.6.13</a> .                                                                                                                                                                     |                                                                           |                                         |
| Software-Index                                         | 16-bit index provided by software at filter programming used by software to identify the matched flow. This parameter is also part of the flow director filter ID that can be reported in the Rx descriptor. |                                                                           |                                         |
| FDIRCMD — Programming Command and Filter Action Set    |                                                                                                                                                                                                              |                                                                           |                                         |

Meaningful depending on the FDIRIP4M.IP4M setting.                                                                                                              | Reserved - Should be zero.<br>All bits in FDIRIP4M.IP4M should be set.                                        |
| FDIRIPSA.IP4SA | IPv4 source address or LS Dword of the source IPv6 address. Meaningful for IPv4 flows depending on the FDIRSIP4M.IP4M setting and for IPv6 flows depending on the FDIRIP6M.SIP6M setting. | Reserved - Should be zero.<br>All bits in FDIRSIP4M.IP4M should be set.<br>FDIRIP6M.SIP6M[3:0] should be set. |

### 7.1.3.6.15 Multiple CPU Cores Considerations

Perfect match filters programming and any query cycles require access to multiple registers. To avoid races between multiple cores, software might need to use one of the following programming methods:

- Use a software-based semaphore between the multiple cores for gaining control over the relevant CSR registers for complete programming or query cycles.
- Manage all programming and queries of the flow director filters by a single core.

Programming signature filters requires only the FDIRHASH and FDIRCMD registers. These two registers are located in 8-byte aligned adjacent addresses. Software could use an 8-byte register for the programming of these registers in a single atomic operation, which avoids the need for any semaphore between multiple cores.

### 7.1.3.6.16 Flow Director Hash Function

The X550 supports programmable 16-bit hash functions based on two 32-bit keys, one for the lookup table identifying a bucket of filters and another one for the signature (*FDIRHKEY* and *FDIRSKEY*). The hash function is described in the sections that follows. In some cases, a smaller hash value than 16 bits is required. In such cases, the LS bits of the hash value are used.

```
For (i=0 to 350) {if (Ext_K[i]) then Hash[15: 0] = Hash[15: 0] XOR Ext_S[15+i: i]}
```

While using the following notations:

'XOR' — Bitwise XOR of two equal length strings

If (xxx) — Equals 'true' if xxx = '1' and equals 'false' if xxx = '0'

S[335:0] — The input bit string of the flow director tuples: 42 bytes listed in [Table 7-11](#) AND-logic with the filters masks.

Ext\_S[n] — S[14:0] | S[335:0] | S[335:321] // concatenated

K[31:0] — The hash key as defined by the FDIRHKEY or FDIRSKEY registers.

Tmp\_K[11\*32-1:0] — (Temp Key) equals K[31:0] | K[31:0]... // concatenated Key 11 times

Ext\_K[350:0] — (Extended Key) equals T\_K[351:1]

The input bit stream for the hash calculation is listed in [Table 7-11](#) while byte 0 is the MSByte (first on the wire) of the VLAN, byte 2 is the MSByte of the source IP (IPv6 case) and so on.

**Table 7-11. Input Bit Stream for Hash Calculation**

| Bytes/Mode    | Field                                                                                                                                                                                                                                            |           |                                                        |

1. In VXLAN and NVGRE packets, the IP Addresses used are of the tunneled header in other packets the outer IP header is used.

### 7.1.3.7 RSS

RSS is a mechanism to distribute received packets into several descriptor queues. Software can then assign each queue to a different processor, therefore sharing the load of packet processing among several processors.

As described in [Section 7.1](#), the X550 uses RSS as one ingredient in its packet assignment policy (the others are the various filters, DCB and virtualization). The RSS output is an RSS index. The X550 global assignment uses these bits (or only some of the LSBs) as part of the queue number.

[Figure 7-9](#) and [Figure 7-10](#) show the process of computing an RSS output:

1. The receive packet is parsed into the header fields used by the hash operation (such as IP Addresses, TCP port, etc.)
2. A hash calculation is performed. The X550 supports a single hash function, as defined by Microsoft\* (MSFT) RSS. The X550 therefore does not indicate to the device driver which hash function is used. The 32-bit result is fed into the *RSS Hash* field in the packet receive descriptor.
3. The X550 supports two modes of RSS defined by the MRQC.MULTIPLE\_RSS bit. When set to 0b a single RSS key and redirection table are supported. In this mode (usually used when virtualization is not enabled) the nine LSBs of the hash result are used as an index into a 512-entry redirection table. Each entry provides up to 6-bit RSS output index ([Figure 7-9](#)).

For SRIOV or VMDQ enabled modes (set by MRQC.MULTIPLE\_RSS set to 1b), The X550 supports up to 64 (one per pool) RSS keys and redirection tables (both can be controlled and programmed at the VF space). In this mode the 6 LSBs of the hash result are used as an index into a 64-entry redirection table. Each entry provides up to 2-bit RSS output index ([Figure 7-10](#)).

When RSS is enabled, the X550 provides software with the following information as required by Microsoft\* RSS and provided for device driver assist:

- A Dword result of the MSFT RSS hash function application to the packet header, to be used by the stack for flow classification, is written into the receive packet descriptor. A 4-bit RSS *Type* field conveys the hash function used for the specific packet.
- Packets to which the RSS function cannot be applied (for example non IP packets) return an *RSS Hash* result of zero, an *RSS Type* of zero and an RSS output index of zero.

### 7.1.3.7.1 Enabling RSS

- RSS is enabled in the MRQC register.
- RSS enabling cannot be done dynamically and must be preceded by a software reset.
- RSS status field in the descriptor write-back is enabled when the RXCSUM.PCSD bit is set (fragment checksum is disabled). RSS is therefore mutually exclusive with UDP fragmentation checksum offload.
- Support for RSS is not provided when legacy receive descriptor format is used.

### 7.1.3.7.2 Disabling RSS

- Disabling RSS on the fly is not allowed, and the X550 must be reset after RSS is disabled.
- When RSS is disabled, packets are assigned an RSS output index = zero.

**Figure 7-9. RSS Block Diagram (`MULTIPLE_RSS = 0b`)**

Figure 7-10. RSS Block Diagram (***MULTIPLE\_RSS = 1b***)

### 7.1.3.7.3 RSS Hash Function

This section provides a verification suite used to validate that the hash function is computed according to MSFT nomenclature.

The X550's hash function follows the MSFT definition. A single hash function is defined with several variations for the following cases:

- **TcpIPv4** — The X550 parses the packet to identify an IPv4 packet containing a TCP segment per the criteria described below. If the packet is not an IPv4 packet containing a TCP segment, RSS is not done for the packet.
- **IPv4** — The X550 parses the packet to identify an IPv4 packet. If the packet is not an IPv4 packet, RSS is not done for the packet.
- **TcpIPv6** — The X550 parses the packet to identify an IPv6 packet containing a TCP segment per the criteria described below. If the packet is not an IPv6 packet containing a TCP segment, RSS is not done for the packet.
- **IPv6** — The X550 parses the packet to identify an IPv6 packet. If the packet is not an IPv6 packet, RSS is not done for the packet.

Tunneled IP to IP packets are considered for the RSS functionality as IP packets. The RSS logic ignores the L4 header while using the outer (first) IP header for the RSS hash.

For NVGRE and VXLAN packets the inner header (IP and TCP/UDP) is used for RSS computations.

The following additional cases are not part of the MSFT RSS specification but are supported RSS modes:

- **UdpIPv4** — The X550 parses the packet to identify a packet with UDP over IPv4.
- **UdpIPv6** — The X550 parses the packet to identify a packet with UDP over IPv6.

A packet is identified as containing a TCP segment if all of the following conditions are met:

- The transport layer protocol is TCP (not UDP, ICMP, IGMP, etc.).
- The TCP segment can be parsed (such as IPv4 options or IPv6 extensions can be parsed, packet not encrypted, etc.).
- The packet is not fragmented (even if the fragment contains a complete L4 header).

**Note:** IPv6 extended headers are parsed by the X550, enabling TCP layer header recognition. Still the IPv6 extended header fields are not taken into account for the queue classification by RSS filter. This rule does not apply for security headers and fragmentation header. Packets with fragmentation header miss this filter. Packets with security extended headers are parsed only up to these headers and therefore can match only filters that do not require fields from the L4 protocol.

Bits[31:16] of the Multiple Receive Queues Command (MRQC), for single RSS and VFMRQC for multiple RSS, registers enable each of the above hash function variations (several might be set at a given time). If several functions are enabled at the same time, priority is defined as follows (skip functions that are not enabled):

- IPv4 packet:
  - Try using the TcpIPv4 function
  - Try using UdpIPv4 function
  - Try using the IPv4 function
- IPv6 packet:
  - Try using the TcpIPv6 function.
  - Try using UdpIPv6 function.
  - Try using the IPv6 function

The following combinations are currently supported:

- Any combination of IPv4, TcpIPv4, and UdpIPv4.
- And/or:
- Any combination of either IPv6, TcpIPv6, and UdpIPv6.

When a packet cannot be parsed by the previous rules, it is assigned an RSS output index = zero. The 32-bit tag (normally a result of the hash function) equals zero.

The 32-bit result of the hash computation is written into the packet descriptor and also provides an index into the redirection table.

The following notation is used to describe the following hash functions:

- Ordering is little endian in both bytes and bits. For example, the IP Address 161.142.100.80 translates into 0xa18e6450 in the signature.
- A “^” denotes bit-wise XOR operation of same-width vectors.
- @x-y denotes bytes x through y (including both of them) of the incoming packet, where byte 0 is the first byte of the IP header. In other words, we consider all byte-offsets as offsets into a packet where the framing layer header has been stripped out. Therefore, the source IPv4 address is referred to as @12-15, while the destination v4 address is referred to as @16-19.
- @x-y, @v-w denotes concatenation of bytes x-y, followed by bytes v-w, preserving the order in which they occurred in the packet.

All hash function variations (IPv4 and IPv6) follow the same general structure. Specific details for each variation are described in the following section. The hash uses a random secret key of length 320 bits (40 bytes); the key is stored in the RSS Random Key Register RSSRK for single RSS and VFRSSRK[63:0] for multiple RSS.

The algorithm works by examining each bit of the hash input from left to right. Our nomenclature defines left and right for a byte-array as follows: Given an array K with k bytes, our nomenclature assumes that the array is laid out as follows:

- K[0] K[1] K[2] ... K[k-1]

K[0] is the left-most byte, and the MSB of K[0] is the left-most bit. K[k-1] is the right-most byte, and the LSB of K[k-1] is the right-most bit.

#### ComputeHash(input[], N)

```
For hash-input input[] of length N bytes (8N bits) and a random secret key K of 320 bits
Result = 0;
For each bit b in input[] {
  if (b == 1) then Result ^= (left-most 32 bits of K);
  shift K left 1 bit position;
}
return Result;
```

### 7.1.3.7.3.1 Pseudo-code Examples

The following four pseudo-code examples are intended to help clarify exactly how the hash is to be performed in four cases, IPv4 with and without ability to parse the TCP header, and IPv6 with and without a TCP header.

#### Hash for IPv4 with TCP

Concatenate SourceAddress, DestinationAddress, SourcePort, DestinationPort into one single byte-array, preserving the order in which they occurred in the packet: Input[12] = @12-15, @16-19, @20-21, @22-23.

```
Result = ComputeHash(Input, 12);
```

#### Hash for IPv4 with UDP

Concatenate SourceAddress, DestinationAddress, SourcePort, DestinationPort into one single byte-array, preserving the order in which they occurred in the packet: Input[12] = @12-15, @16-19, @20-21, @22-23.

```
Result = ComputeHash(Input, 12);
```

#### Hash for IPv4 without TCP

Concatenate SourceAddress and DestinationAddress into one single byte-array

```
Input[8] = @12-15, @16-19
Result = ComputeHash(Input, 8)
```

#### Hash for IPv6 with TCP

Similar to previous:

```
Input[36] = @8-23, @24-39, @40-41, @42-43
Result = ComputeHash(Input, 36)
```

### Hash for IPv6 with UDP

Similar to previous:

```

Input[36] = @8-23, @24-39, @40-41, @42-43
Result = ComputeHash(Input, 36)

```

### Hash for IPv6 without TCP

```

Input[32] = @8-23, @24-39
Result = ComputeHash(Input, 32)

```

## 7.1.3.7.4 Redirection Tables

The redirection table used for single RSS mode (RETA - [Section 8.2.2.8.18](#) and ERETA - [Section 8.2.2.8.24](#)) is a 512-entry structure, indexed by the nine LSBs of the hash function output.

The redirection tables used for multiple RSS mode (VFRETA - [Section 8.3.2.3.12](#)) are 64-entry structures indexed by the six LSBs of the hash function output. The table to use is defined by the pool to which the packet is sent.

System software might update the redirection tables during run time. Such updates of the table are not synchronized with the arrival time of received packets. Therefore, it is not guaranteed that a table update takes effect on a specific packet boundary.

## 7.1.3.7.5 RSS Verification Suite

Assume that the random key byte-stream is:

```

0x6d, 0x5a, 0x56, 0xda, 0x25, 0x5b, 0x0e, 0xc2,
0x41, 0x67, 0x25, 0x3d, 0x43, 0xa3, 0x8f, 0xb0,
0xd0, 0xca, 0x2b, 0xcb, 0xae, 0x7b, 0x30, 0xb4,
0x77, 0xcb, 0x2d, 0xa3, 0x80, 0x30, 0xf2, 0x0c,
0x6a, 0x42, 0xb7, 0x3b, 0xbe, 0xac, 0x01, 0xfa

```

**Table 7-12. IPv4**

| Destination Address/Port | Source Address/Port  | IPv4 only  | IPv4 with TCP |
|--------------------------|----------------------|------------|---------------|
| 161.142.100.80:1766      | 66.9.149.187:2794    | 0x323e8fc2 | 0x51ccc178    |
| 65.69.140.83:4739        | 199.92.111.2:14230   | 0xd718262a | 0xc626b0ea    |
| 12.22.207.184:38024      | 24.19.198.95:12898   | 0xd2d0a5de | 0x5c2b394a    |
| 209.142.163.6:2217       | 38.27.205.30:48228   | 0x82989176 | 0xafc7327f    |
| 202.188.127.2:1303       | 153.39.163.191:44251 | 0x5d1809c5 | 0x10e828a2    |

**Note:** The IPv6 address tuples are only for verification purposes, and may not make sense as a tuple.

**Table 7-13. IPv6**

| Destination Address/Port         | Source Address/Port                         | IPv6 only  | IPv6 with TCP |
|----------------------------------|---------------------------------------------|------------|---------------|
| 3ffe:2501:200:3::1 (1766)        | 3ffe:2501:200:1fff::7 (2794)                | 0x2cc18cd5 | 0x40207d3d    |

## 7.1.4 Receive Data Storage in System Memory

The X550 posts receive packets into data buffers in system memory.

The following controls are provided for the data buffers:

- The `SRRCTL[n].BSIZEPACKET` field defines the size of the data buffer pointed by each descriptor. The maximum packet size that can be posted to a queue can be limited using the `RXDCTL[n].RLPML` field. This filter enables software to use smaller buffers than the size defined by the `SRRCTL[n].BSIZEPACKET`.

**Note:** The packet size compared to `RXDCTL[n].RLPML` does not include any parts stripped by the device like CRC VLAN or other tags but include additional Timestamp appended to the packet.

- The `SRRCTL[n].BSIZEHEADER` field defines the size of the header buffer pointed by each descriptor (advanced descriptors only).
- Each queue is provided with a separate `SRRCTL` register.

Receive memory buffer addresses are word (2 x byte) aligned (both data and headers).

The internal receive buffers are described in [Section 7.6.3.1](#).

## 7.1.5 Receive Descriptors

### 7.1.5.1 Legacy Receive Descriptor Format

A receive descriptor is a data structure that contains the receive data buffer address and fields for hardware to store packet information. Upon receipt of a packet for this device, hardware stores the packet data into the indicated buffer and writes the length, status and errors to the receive descriptor. If `SRRCTL[n].DESCTYPE = zero`, the X550 uses the Legacy Rx descriptor as listed in [Table 7-14](#). The shaded areas indicate fields that are modified by hardware upon packet reception (so-called descriptor write-back).

Legacy descriptors should not be used when advanced features are enabled: SCTP, Virtualization, DCB, IPsec, FCoE, Time stamp in Packet, tunnel packets checksum or RSC. Packets that match these cases might be dropped from queues that use legacy receive descriptors.

Refer to [Table 7-14](#) and the field descriptions that follow.

**Table 7-14. Legacy Receive Descriptor (RDESC) Layout**

|   | 63                    | 48 | 47     | 40 | 39     | 32 | 31                | 16 | 15     | 0 |
|---|-----------------------|----|--------|----|--------|----|-------------------|----|--------|---|
| 0 | Buffer Address [63:0] |    |        |    |        |    |                   |    |        |   |
| 8 | VLAN Tag              |    | Errors |    | Status |    | Fragment Checksum |    | Length |   |

[Buffer Address \(64-bit offset 0, 1st line\)](#)

Physical address in host memory of the received packet buffer.

[Length Field \(16-bit offset 0, 2nd line\)](#)

The length indicated in this field covers the data written to a receive buffer including CRC bytes (if any). Software must read multiple descriptors to determine the complete length for packets that span multiple receive buffers.

**Fragment Checksum (16-bit offset 16, 2nd line)**

This field is used to provide the fragment checksum value. This field is equal to the unadjusted 16-bit ones complement of the packet. Checksum calculation starts at the L4 layer (after the IP header) until the end of the packet excluding the CRC bytes. To use the fragment checksum assist to offload L4 checksum verification, software might need to back out some of the bytes in the packet. For more details see [Section 7.1.6.5](#).

The fragment checksum is always reported in the descriptor with the EOP bit set.

**Status Field (8-bit offset 32, 2nd line)**

Status information indicates whether the descriptor has been used and whether the referenced buffer is the last one for the packet. Error status information is listed in [Table 7-16](#).

**Table 7-15. Receive Status (RDESC.STATUS) Layout**

| 7   | 6    | 5    | 4     | 3  | 2        | 1   | 0  |
|-----|------|------|-------|----|----------|-----|----|
| PIF | IPCS | L4CS | UDPCS | VP | Reserved | EOP | DD |

- **End of Packet (EOP) and Descriptor Done (DD)** — Refer to the following table:

| DD | EOP | Description                                                                                                                                                                                                                          |
|----|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0  | 0   | Software setting of the descriptor when it hands it to the hardware.                                                                                                                                                                 |
| 0  | 1   | Reserved (invalid option).                                                                                                                                                                                                           |
| 1  | 0   | A completion status indication for non-last descriptor of a packet that spans across multiple descriptors. It means that the hardware is done with the descriptor and its buffers while only the length is valid on this descriptor. |
| 1  | 1   | A completion status indication of the entire packet. Software might take ownership of its descriptors while all fields in the descriptor are valid.                                                                                  |

- **VP (VLAN Packet)** — When set, the *VP* field indicates that the incoming packet's type is a VLAN (802.1q, matching the *VLNCTRL.VET*). If the *RXDCTL.VME* bit is set as well, an active *VP* field also means that the VLAN has been stripped from the packet to the receive descriptor. For a further description of 802.1q VLANs please see [Section 7.4](#).
- **IPCS (IPv4 Checksum), L4CS (L4 Checksum), UDPCS (UDP Checksum)** — These bits are described in the following table.

**Note:** Switched packets from a local VM that do not use the Tx IP checksum offload by hardware have the *IPCS* equal to zero; switched packets from a local VM that do not use the Tx L4 checksum offload by hardware have the *L4CS* and *UDPCS* equal to zero.

| L4CS | UDPCS | IPCS | Functionality                                                                                                                                                                               |
|------|-------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0    | 0     | 0    | Hardware does not provide checksum offload.                                                                                                                                                 |
| 0    | 0     | 1    | Hardware provides IPv4 checksum offload. Pass/fail indication is provided in the <i>Error</i> field – <i>IPE</i> .                                                                          |
| 1    | 0     | 1/0  | Hardware provides IPv4 checksum offload if <i>IPCS</i> is active along with TCP checksum offload. Pass/fail indication is provided in the <i>Error</i> field – <i>IPE</i> and <i>TCPE</i> . |
| 1    | 1     | 1/0  | Hardware provides IPv4 checksum offload if <i>IPCS</i> is active along with UDP checksum offload. Pass/fail indication is provided in the <i>Error</i> field – <i>IPE</i> and <i>TCPE</i> . |

IPv6 packets do not have the *IPCS* bit set, but might have the *L4CS* bit and *UDPCS* bit set if the X550 recognizes the transport header.

- **PIF (Non Unicast Address)** — The *PIF* bit is set on packets with a non-unicast destination Ethernet MAC Address — multicast and broadcast.

#### Error Field (8-bit offset 40, 2nd line)

Table 7-16 and the following text describes the possible errors reported by the hardware.

**Table 7-16. Receive Errors (RDESC.ERRORS) Layout**

| 7   | 6    | 5        | 4        | 3        | 2        | 1        | 0   |
|-----|------|----------|----------|----------|----------|----------|-----|
| IPE | TCPE | Reserved | Reserved | Reserved | Reserved | Reserved | RXE |

- **IPE (IPv4 Checksum Error)** — The IP checksum error is valid only when the *IPCS* bit in the *Status* field is set (indicating that the hardware validated the IP checksum). This bit is meaningful only on the last descriptor of a packet while the *EOP* bit is set as well. Packets with IP error are posted to host memory regardless of the store bad packet setting (*FCTRL.SBP*).
- **TCPE (TCP/UDP Checksum Error)** — The TCP/UDP checksum error is valid only when the *L4CS* bit in the *Status* field is set (indicating that the hardware validated the L4 checksum). This bit is meaningful only on the last descriptor of a packet while the *EOP* bit is set as well. Packets with a TCP/UDP error are posted to host memory regardless of the store bad packet setting (*FCTRL.SBP*).

IPv4/UDP packets that carry a null UDP checksum field are reported with *L4CS* = 0 and *TCPE* = 0 (valid packet with no checksum).

IPv6/UDP packets that carry a null UDP checksum field are reported with *L4CS* = 1 and *TPCE* = 1 (UDP checksum is mandatory over IPv6).

- **RXE**— The RXE error bit is an indication for any MAC error. It is a logic OR function of the following errors:
  - CRC or symbol error might be a result of receiving a /V/ symbol on the TBI interface, /FE/ symbol on the GMII/XGMII interface, RX\_ER assertion on GMII interface, bad EOP or loss of sync during packet reception.
  - Undersize frames shorter than 64 bytes.
  - Oversize frames larger than the *MFS* definition in the *MAXFRS* register.
  - Length error in 802.3 packet format. *Length* field is not checked in presence of a VLAN or E-Tag.

Packets with an RXE error are posted to host memory only when store bad packet bit (*FCTRL.SBP*) is set.

#### VLAN Tag Field (16-bit offset 48, 2nd line)

If the *RXDCTL.VME* is set and the received packet type is 802.1q (as defined by *VLNCTRL.VET*), the VLAN header is stripped from the packet data storage. In this case the 16 bits of the VLAN tag, priority tag and DEI from the received packet are posted to the *VLAN Tag* field in the receive descriptor. Otherwise, the *VLAN Tag* field contains 0x0000.

**Table 7-17. VLAN Tag Field Layout (for 802.1q Packet)**

| 15  | 13  | 12   | 11 | 0 |
|-----|-----|------|----|---|
| PRI | DEI | VLAN |    |   |

Priority and DEI are part of 802.1Q specifications. The VLAN field is provided in network order.

## 7.1.5.2 Advanced Receive Descriptors

### 7.1.5.2.1 Advanced Receive Descriptors — Read Format

Table 7-18 lists the advanced receive descriptor programming by the software. The `SRRCTL[n].DESCTYPE` should be set to a value other than 000b when using the advanced descriptor format.

**Table 7-18. Descriptor Read Format**

|   |                              |   |    |
|---|------------------------------|---|----|
|   | 63                           | 1 | 0  |
| 0 | Packet Buffer Address [63:1] |   |    |
| 8 | Header Buffer Address [63:1] |   | DD |

#### Packet Buffer Address (64)

The physical address in host memory of the packet buffer.

#### Header Buffer Address (64)

The physical address in host memory of the header buffer with the lowest bit being Descriptor Done (DD). When a packet spans in multiple descriptors, only the header buffer of the first descriptor is used. In subsequent descriptors, only the data buffer is used.

During the programming phase, software must set the *DD* bit to zero (see the description of the *DD* bit in this section). This means that header buffer addresses are always word aligned.

**Note:** The X550 does not support null descriptors meaning packet or header addresses are zero.

### 7.1.5.2.2 Advanced Receive Descriptors — Write-Back Format

When the X550 writes back the descriptors, it uses the format listed in Table 7-19. The advanced descriptor writeback format is used when `SRRCTL[n].DESCTYPE` is set to a value other than 000b.

**Table 7-19. Descriptor Write-Back Format**

|   |                                                                      |    |         |    |                |         |    |        |                         |             |   |          |   |   |
|---|----------------------------------------------------------------------|----|---------|----|----------------|---------|----|--------|-------------------------|-------------|---|----------|---|---|
|   | 63                                                                   | 48 | 47      | 32 | 31             | 30      | 21 | 20     | 17                      | 16          | 4 | 3        | 0 |   |
| 0 | RSS Hash / Fragment Checksum / FCoE_PARAM / Flow Director Filters ID |    |         |    | SPH            | HDR_LEN |    | RSCCNT |                         | Packet Type |   | RSS Type |   |   |
| 8 | VLAN Tag                                                             |    | PKT_LEN |    | Extended Error |         |    |        | Extended Status / NEXTP |             |   |          |   |   |
|   | 63                                                                   | 48 | 47      | 32 | 31             | 20      |    | 19     |                         |             |   |          |   | 0 |

#### RSS Type (4-bit offset 0, 1st line)

The X550 must identify the packet type and then choose the appropriate RSS hash function to be used on the packet. The RSS type reports the packet type that was used for the RSS hash function.

| RSS Type | Description                              |
|----------|------------------------------------------|
| 0x0      | No hash computation done for this packet |
| 0x1      | HASH_TCP_IPv4                            |
| 0x2      | HASH_IPv4                                |
| 0x3      | HASH_TCP_IPv6                            |

| RSS Type  | Description                                                                                                              |
|-----------|--------------------------------------------------------------------------------------------------------------------------|
| 0x4       | Reserved                                                                                                                 |
| 0x5       | HASH_IPv6                                                                                                                |
| 0x6       | Reserved                                                                                                                 |
| 0x7       | HASH_UDP_IPv4                                                                                                            |
| 0x8       | HASH_UDP_IPv6                                                                                                            |
| 0x9 – 0xE | Reserved                                                                                                                 |
| 0xF       | Packet reports flow director filters status (set if flow director match, even if packet is forwarded by another filter). |

### Packet Type (13-bit at offset 4, 1st line)

The *Packet Type* field reports the packet type identified by the hardware as follows. Note that some of the fields in the receive descriptor are valid for specific packet types.

| Bit Index | Bit 11 = 0                                                                         | Bit 11 = 1 (L2 packet matching one of the ETQF filters)                                                              |
|-----------|------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|
| 0         | IPv4 — IPv4 header present                                                         | Ethertype — <i>ETQF</i> register index that matches the packet. Special types are defined for 802.1X, 1588 and FCoE. |
| 1         | IPv4O — IPv4 with options                                                          |                                                                                                                      |
| 2         | IPv6 — IPv6 header present                                                         |                                                                                                                      |
| 3         | IPv6E- IPv6 with extensions                                                        | Reserved.                                                                                                            |
| 4         | TCP — TCP header present                                                           |                                                                                                                      |
| 5         | UDP — UDP header present                                                           |                                                                                                                      |
| 6         | SCTP — SCTP header                                                                 | Reserved.                                                                                                            |
| 7         | If bit 12 = 0 - Reserved<br>If bit 12 = 1:<br>0b = NVGRE<br>1b = XLAN              |                                                                                                                      |
| 8         | IPsec ESP – IPsec encapsulation                                                    |                                                                                                                      |
| 9         | IPsec AH – IPsec encapsulation                                                     |                                                                                                                      |
| 10        | Reserved                                                                           | Reserved.                                                                                                            |
| 11        | 0b = non L2 packet                                                                 | 1b = L2 packet                                                                                                       |
| 12        | NVGRE or VXLAN Tunnel Packet. If this bit is set, bit 7 indicates the tunnel type. | Reserved.                                                                                                            |

**Note:** UDP, TCP and IPv6 indications are not set in any IPv4 fragmented packet.

In virtualization mode, packets might be received from other local VMs. The X550 does not check the L5 header for these packets and does not report NFS header. If such packets carry IP tunneling (IPv4 — IPv6), they are reported as IPv4E. The packets received from local VM are indicated by the *LB* bit in the status field. To be identified, the *CC* bit in the transmit descriptor must be set and if it is a tunnel packet, the *TUNNEL.OUTERIPCS* must be set also. If bit 12 (Tunnel Packet) is set, all the L3/L4 indications (IPv4, IPv4O, IPv6, IPv6E, TCP, UDP, SCTP) reflects the inner header status.

**RSC Packet Count- RSCCNT (4-bit offset 17, 1st line)**

The *RSCCNT* field is valid only for RSC descriptors while in non-RSC it equals zero. *RSCCNT* minus one indicates the number of coalesced packets that start in this descriptor. *RSCCNT* might count up to 14 packets. Once 14 packets are coalesced in a single buffer, RSC is closed enabling accurate coalesced packet count. If the *RSCCNTBP* bit in *RDRXCTL* is set, coalescing might proceed beyond the 14 packets per buffer while *RSCCNT* stops incrementing beyond 0xF.

**Note:** Software can identify RSC descriptors by checking the *RSCCNT* field for non-zero value.

**HDR\_LEN (10-bit offset 21, 1st line)**

The *HDR\_LEN* reflects the size of the packet header in byte units (if the header is decoded by the hardware). This field is meaningful only in the first descriptor of a packet and should be ignored in any subsequent descriptors. Header split is explained in [Section 7.1.6](#) while the packet types for this functionality are enabled by the *PSRTYPE[n]* registers.

**Split Header — SPH (1-bit offset 31, 1st line)**

When set to 1b, indicates that the hardware has found the length of the header. If set to 0b, the header buffer may be used only in split always mode. If the received header size is greater or equal to 1024 bytes, the *SPH* bit is not set and header split functionality is not supported. The *SPH* bit is meaningful in all the descriptors of a packet. See additional details on *SPH*, *PKT\_LEN* and *HDR\_LEN* as a function of split modes in [Table 7-24](#).

| Packet Type                                                                                                                                          | Header Length<br>(Includes All Fields Up to the<br>Field Specified) | Header Split         |
|------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------|----------------------|
| Un-recognized EtherType only with/without SNAP and with/without VLAN, or packets that match the L2 filters (MTQF) other than FCoE with/without VLAN. | VLAN header(s) if present. Else, <i>EtherType</i> field             | No                   |
| FCoE packet without ESP option header.                                                                                                               | FC header including FC options                                      | N/A <sup>1</sup>     |
| FCoE packet with ESP option header.                                                                                                                  | FC header excluding FC options                                      | N/A <sup>1</sup>     |
| Pv4 only or fragmented IPv4 with any payload including IPv4-IPv6 tunneling.                                                                          | IPv4 header                                                         | Enabled              |
| Non-fragmented IPv4, TCP / UDP / SCTP.                                                                                                               | L4 header                                                           | Enabled              |
| IPv4-IPv6, only or fragmented IPv4-IPv6 at IPv6 header with any payload.                                                                             | IPv6 header (up to the fragment extension header if exist)          | Enabled              |
| IPv4-IPv6, TCP / UDP / SCTP.                                                                                                                         | L4 header                                                           | Enabled              |
| VXLAN or NVGRE.                                                                                                                                      | Cloud Header/L2 Header                                              | Enabled <sup>2</sup> |

1. Header split is not permitted in queues that might receive FCoE packets.

2. If cloud split modes used (*PSRTYPE15* or *PSRTYPE16* are set). If not, according to internal header.

**RSS Hash or FCOE\_PARAM or Flow Director Filters ID (32-bit offset 32, 1st line) / Fragment Checksum (16-bit offset 48, 1st line)**

This field has multiplexed functionality according to the received packet type (reported on the *Packet Type* field in this descriptor) and device setting.

- **FCoE\_PARAM** — For FCoE packets that matches a valid DDP context, this field holds the *PARAM* field in the DDP context after processing the received packet. If the *Relative Offset Present* bit in the *F\_CTL* was set in the data frames, the *PARAM* field indicates the size in bytes of the entire exchange inclusive the frame reported by this descriptor. This field is valid for FCoE packets for which the *FCSTAT* field is non zero.

- **Fragment Checksum** — For fragmented UDP/IP packets, this field holds the UDP fragment checksum (described in [Section 7.1.6.5](#)) if both the `RXCSUM.PCSD` bit is cleared and `RXCSUM.IPPCSE` bit is set. This field is meaningful only for UDP packets where the `UDPV` bit in the *Extended Status* word is set. When Fragment Checksum is reported, bits 47:32 are invalid.

The checksum does not include any padding or timestamp added by the device.

- **RSS Hash / Flow Director Filters ID** — For non-FCoE packets, if the `RXCSUM.PCSD` bit is set, this field holds the RSS hash value or flow director filters ID.
  - If the `FDIRCTRL.REPORT_STATUS` bit is set, the flow director filters ID is reported;
  - If the RSS Type is non zero, the RSS hash is reported.
  - Otherwise, the value is not valid.

**Table 7-20. Checksum Enable/Disable**

| <code>RXCSUM.PCSD</code> | 0 (Checksum Enable)                                                        | 1 (Checksum Disable)                             |
|--------------------------|----------------------------------------------------------------------------|--------------------------------------------------|
|                          | Fragment Checksum and IP Identification are reported in the Rx Descriptor. | RSS Hash value is reported in the Rx Descriptor. |

- **RSS Hash** — The RSS hash value is required for RSS functionality as described in [Section 7.1.3.7](#). Note that the RSS hash is meaningful only for 'RSS Type' in the range 0x1 to 0x8.
- **Flow Director Filters ID** — The flow director filters ID is reported only when the received packet matches a flow directory filter (see [Section 7.1.3.6](#)). The flow director filter ID field has a different structure for signature-based filters and perfect match filters as follows:

| Filter Type                           | 31  | 30          | 29 | 28 | 16   | 15        | 13  | 12 | 0        |
|---------------------------------------|-----|-------------|----|----|------|-----------|-----|----|----------|
| Hash-based Flow Director Filter ID    | Rsv | Bucket Hash |    |    |      | Signature |     |    |          |
| Perfect Match Flow Director Filter ID | Rsv |             |    |    | Hash |           | Rsv |    | SW-Index |

- **Bucket Hash** — A hash value that identifies a flow director bucket. When the Flow Director table is smaller than 32 K filters the bucket hash is smaller than 15 bits. In this case the upper bit(s) are set to zero.
- **Signature** — A hash value used to identify flow within a bucket.
- **SW-Index** — The SW-Index that is taken from the filter context, programmed by software. It is meaningful only when the `FLM` bit in the *Extended Status* is set as well.
- **Rsv** — Reserved.

#### Extended Status / NEXTP (20-bit offset 0, 2nd line)

Status information indicates whether the descriptor has been used and whether the referenced buffer is the last one for the packet. [Table 7-21](#) lists the *Extended Status* word in the last descriptor of a packet (`EOP` bit is set). [Table 7-22](#) lists the *Extended Status* word in any descriptor but the last one of a packet (`EOP` bit is cleared).

**Table 7-21. Receive Status (RDESC.STATUS) Layout of Last Descriptor**

| 19   | 18        | 17   | 16     | 15     | 14    | 13 | 12  | 11  | 10   |
|------|-----------|------|--------|--------|-------|----|-----|-----|------|
| BMC  | LB        | SECP | TS     | TSIP   | Rsv   |    |     | Rsv | UDPV |
| VEXT | OUTERIPCS | PIF  | IPCS   | L4I    | UDPCS | VP | FLM | EOP | DD   |
|      |           |      | FCEOFs | FCSTAT |       |    |     |     |      |
| 9    | 8         | 7    | 6      | 5      | 4     | 3  | 2   | 1   | 0    |

**Table 7-22. Receive Status (RDESC.STATUS) Layout of Non-Last Descriptor**

| 19                              | 4 | 3:2 | 1        | 0  |
|---------------------------------|---|-----|----------|----|
| Next Descriptor Pointer — NEXTP |   | Rsv | EOP = 0b | DD |

- *Rsv (14:11)* — Reserved at zero.
- *FLM(2)* — Flow director filter match indication is set for packets that match these filters.
- *VP(3), PIF (7)* — These bits are described in the legacy descriptor format in [Section 7.1.5](#). The VP bit is not set even if a VLAN tag is present if the PFQDE.HIDE\_VLAN bit is set for the queue.
- *EOP (1) and DD (0)* — *End of Packet* and *Done* bits are listed in the following table:

| DD | EOP | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0  | X   | Software setting of the descriptor when it hands it to hardware.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 1  | 0   | A completion status indication for a non last descriptor of a packet (or multiple packets in the case of RSC) that spans across multiple descriptors. In a single packet case the <i>DD</i> bit indicates that the hardware is done with the descriptor and its buffers. In the case of RSC, the <i>DD</i> bit indicates that the hardware is done with the descriptor but might still use its buffers (for the coalesced header) until the last descriptor of the RSC completes.<br>Only the <i>Length</i> fields are valid on this descriptor. In the RSC case, the next descriptor pointer and RSCCNT are valid as well. |
| 1  | 1   | A completion status indication of the entire packet (or the multiple packets in the case of RSC) and software might take ownership of its descriptors.<br>All fields in the descriptor are valid (reported by the hardware).                                                                                                                                                                                                                                                                                                                                                                                                |

- *UDPCS (4), L4I (5) / FCSTAT (5:4)* — This field has multiplexed functionality for FCoE and non-FCoE packets. Hardware identifies FCoE packets in the filter unit and indicates it in the *Packet Type* field in the Rx descriptor. For non-FCoE packets this field is UDPCS and L4I. The UDPCS (UDP checksum) is set (together with L4CS bit) when hardware provides UDP checksum offload. The L4I (L4 Integrity) is set when hardware provides any L4 offload as: UDP checksum, TCP checksum or SCTP CRC offload. For FCoE packets, this field represents the FCSTAT (FCoE Status) as follows:

| FCSTAT | Meaning                                                                                                                                                                                                                                                                                                               |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 00     | No match to any active FC context                                                                                                                                                                                                                                                                                     |
| 01     | FCoE frame matches an active FC context with no DDP. The entire frame is posted to the receive buffer indicated by this descriptor.                                                                                                                                                                                   |
| 10     | FCP_RSP frame received that invalidates an FC read context or last data packet in a sequence with sequence initiative set that invalidates an FC write context.                                                                                                                                                       |
| 11     | FCoE frame matches an active FC context and found liable for DDP by the filter unit. The packet's data was posted directly to the user buffers if no errors were found by the DMA unit as reported in the <i>FCERR</i> field. If any error is found by the DMA unit the entire packet is posted to the legacy queues. |

- **IPCS(6), FCEOFs (6)** — This bit has multiplexed functionality for FCoE and non-FCoE packets. The hardware identifies FCoE packets in the filter unit and indicates it in the *Packet Type* field in the Rx descriptor.

For non-FCoE packets it is IPCS as described in Legacy Rx descriptor (in [Section 7.1.5](#)).

For FCoE packets, this bit and the *FCEOFe* bit in the *Extended Error* field indicates the received EOF code as follows:

| FCEOFe | FCEOFs | Description and Digested Meaning and Device Behavior                                     |
|--------|--------|------------------------------------------------------------------------------------------|
| 0      | 0      | EOFn. Nominal operation, DDP is enabled.                                                 |
| 0      | 1      | EOFt. Nominal operation (end of sequence), DDP is enabled.                               |
| 1      | 0      | Unexpected EOFn-EOFt or SOFi-SOFn. No DDP while filter context is updated by the packet. |
| 1      | 1      | EOFa, EOFni or un-recognized EOF / SOF. No DDP while filter context is invalidated.      |

- **OUTERIPCS(8)** — Indicates that a checksum was done on the outer IP header of an NVGRE or VXLAN packet.
- **VEXT (9)** — Outer-VLAN is found on a double VLAN packet. This bit is valid only when CTRL\_EXT.EXTENDED\_VLAN is set. See more details in [Section 7.4.5](#).
- **UDPV (10)** — The *UDP Checksum Valid* bit indicates that the incoming packet contains a valid (non-zero value) checksum field in an incoming fragmented (non-tunneled) UDP IPv4 packet. It means that the *Fragment Checksum* field in the receive descriptor contains the UDP checksum as described in [Section 7.1.6.5](#). When this field is cleared in the first fragment that contains the UDP header, it means that the packet does not contain a valid UDP checksum and the checksum field in the Rx descriptor should be ignored. This field is always cleared in incoming fragments that do not contain the UDP header.
- **TSIP (15)** — Timestamp in packet. The *Timestamp In Packet* bit is set to indicate that the received packet arrival time was captured by the hardware and the timestamp was placed in the receive buffer. For more details see [Section 7.7](#) and [Section 7.1.6.2](#).
- **TS (16)** — The *Time Stamp* bit is set when the device recognized a time sync packet. In such a case the hardware captures its arrival time and stores it in the Time Stamp register. For more details see [Section 7.7](#).
- **SECP (17)** — *Security Processing* bit indicates that the hardware identified the security encapsulation and processed it as configured.
  - **IPsec processing** — This bit is set only if a matched SA was found. Note that hardware does not process packets with an IPv4 option or IPv6 extension header and the *SECP* bit is not set. This bit is not set for IPv4 packets shorter than 70 bytes, IPv6 ESP packets shorter than 90 bytes, or IPv6 AH packets shorter than 94 bytes (all excluding CRC). Note that these packet sizes are never expected and set the length error indication in the *SECERR* field.
- **LB (18)** — This bit provides a loopback status indication which means that this packet is sent by a local VM (VM to VM switch indication).
- **BMC (19)** — Packet received from BMC. The *BMC* bit is set to indicate the packet was sent by the local BMC. Bit is cleared if packet arrives from the network. For more details see [Section 11.4.2.2](#).

- **NEXTP (19:4)** — Large receive might be composed of multiple packets and packets might span in multiple buffers (descriptors). These buffers are not guaranteed to be consecutive while the *NEXTP* field is a pointer to the next descriptor that belongs to the same RSC. The *NEXTP* field is defined in descriptor unit (the same as the head and tail registers). The *NEXTP* field is valid for any descriptor of a large receive (the *EOP* bit is not set) except the last one. It is valid even in consecutive descriptors of the same packet. In the last descriptor (on which the *EOP* bit is set), *NEXTP* is not indicated but rather all other status fields previously described in this section.

Extended Error (12-bit offset 21, 2nd line)

Table 7-23 and the following text describe the possible errors reported by hardware.

**Table 7-23. Receive Errors (RDESC.ERRORS) Layout**

| 11     | 10  | 9   | 8:7    | 6         | 5:4 | 3   | 2:0             |
|--------|-----|-----|--------|-----------|-----|-----|-----------------|
| IPE    | L4E | RXE | SECERR | OUTERIPER | Rsv | HBO | FCERR / FDIRERR |
| FCEOFc |     |     |        |           |     |     |                 |

- **FCERR (2:0)** — Defines error cases for FCoE packets. Note that hardware indicates FCoE packet recognition on the *Packet Type* field in the Rx descriptor. Packets with FCERR are posted to host memory regardless of the store bad packet setting in the Filter Control register. This field must be ignored when FCSTAT is 00b.

| FCERR Code | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 000        | No exception errors found                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 001        | Bad FC CRC. Hardware does not check any other FC fields in the packet.                                                                                                                                                                                                                                                                                                                                                                                                          |
| 010        | One of the following error indications found by the filter unit (hardware auto-invalidates a matched DDP filter context if exists): <ul style="list-style-type: none"> <li>1. Received non-zero abort sequence condition in the <i>F_CTL</i> field in FC read packet.</li> <li>2. Received EOFa or EOFni or any un-recognized EOF or SOF flags.</li> </ul>                                                                                                                      |
| 011        | The DMA unit gets FCoE packets that match a DDP context while it missed the packet that was marked as first by the filter unit. Filter context parameters might be updated while DMA context parameters are left intact (see error code 101b).                                                                                                                                                                                                                                  |
| 100        | One of the following cases: <ul style="list-style-type: none"> <li>1. Unsupported FCoE version. <i>FCSTAT</i> equals to 00b.</li> <li>2. Out of order reception (<i>SEQ_CNT</i> does not match expected value) of a packet that matches an active DDP context. The filter unit might set the <i>FCSTAT</i> to 01b, or 10b.</li> </ul>                                                                                                                                           |
| 101        | No DMA resources due to one of the following cases listed while the hardware auto-invalidates the DDP DMA context. Software should invalidate the filter context before it can reuse it. <ul style="list-style-type: none"> <li>1. Last buffer exhausted (no space in the user buffers).</li> <li>2. Legacy receive queue is not enabled or no legacy receive descriptor.</li> <li>3. Some cases of a missed packet as described in <i>FCERR</i> code 011b and 110b.</li> </ul> |
| 110        | Filter context valid and DMA context invalid. Indicates that some packet(s) were lost by the DMA context due to lack of legacy receive descriptors or were missed by the Rx packet buffer. <ul style="list-style-type: none"> <li>1. This error code might also be received in some cases of a missed packet as described in <i>FCERR</i> code 011b.</li> </ul>                                                                                                                 |
| 111        | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

- **FDIRERR (2:0)** — This field is relevant for non-FCoE packets when the flow director filters are enabled.
  - **FDIRErr(0) - Length** — If the flow director filter matches the *Length* bit, this indicates that the distance of the matched filter from the hash table exceeds the FDIRCTRL.Max-Length. If there is no matched filter, the *Length* bit is set if the flow director linked list of the matched hash value exceeds the FDIRCTRL.Max-Length.
  - **FDIRErr(1) - Drop** — The *Drop* bit indicates that a received packet matched a flow director filter with a drop action. In the case of perfect mode filtering, it is expected to find the drop indication only when the linked list in the flow director bucket exceeds the permitted Max-Length. In this case, the packet is not dropped. Instead, it is posted to the Rx queue (indicated in the filter context) for software handling of the Max-Length exception. In the case of hash mode filtering, it is expected that the drop queue is always a valid queue so all packets that match the drop filter are visible to software.
  - **FDIRErr(2) - Coll** — A matched flow director filter with a collision indication was found. The collision indicates that software attempted to step over this filter with a different action that was already programmed.
- **HBO (3)** — The *Header Buffer Overflow* bit is set if the packet header (calculated by hardware) is bigger than the header buffer (defined by SSRCTL.BSIZEHEADER). *HBO* reporting might be used by software to allocate bigger buffers for the headers. It is meaningful only if the *SPH* bit in the receive descriptor is set as well. The *HDR\_LEN* field is valid even when the *HBO* bit is set. Packets with HBO error are posted to host memory regardless of the store bad packet setting (FCTRL.SBP). Packet DMA to its buffers when the *HBO* bit is set, depends on the device settings as follows:

| SSRCTL.DESCTYPE          | DMA Functionality                                                                                                    |
|--------------------------|----------------------------------------------------------------------------------------------------------------------|
| Header Split (010b)      | The header is posted with the rest of the packet data to the packet buffer.                                          |
| Always Split Mode (101b) | The header buffer is used as part of the data buffers and contains the first SSRCTL.BSIZEHEADER bytes of the packet. |

- **Rsv (5:4)** — Reserved at zero.
- **OUTERIPER (6)** — Indicates an error was found in the checksum of an outer IP header of a VXLAN or NVGRE packet or that the UDP checksum of the outer UDP header in a VXLAN packet was not zero.
- **SECERR (8:7)** — Security error indication for IPsec. This field is meaningful only if the *SECP* bit in the extended status is set.

| SECERR | IPsec Error Reporting                                                                                                                                                                                                                                                                                                                                                                                  |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 00     | No errors found while an active SA found or no security processing.                                                                                                                                                                                                                                                                                                                                    |
| 01     | Invalid IPsec Protocol: IPsec protocol field ( <i>ESP</i> or <i>AH</i> ) in the received IP header does not match expected one stored in the SA table.                                                                                                                                                                                                                                                 |
| 10     | Length error: ESP packet is not 4-bytes aligned or AH/ESP header is truncated (for example, a 28-byte IPv4 packet with IPv4 header + ESP header that contains only SPI and SN) or AH <i>Length</i> field in the AH header is different than 0x07 for IPv4 or 0x08 for IPv6 or the entire packet size excluding CRC is shorter than 70 bytes for IPv4 or 90 bytes for IPv6 ESP or 94 bytes for IPv6 AH. |
| 11     | Authentication failed: Bad signature.                                                                                                                                                                                                                                                                                                                                                                  |

- **RXE (9)** — RXE is described in the legacy descriptor format in [Section 7.1.5](#).

- **L4E (10)** — L4 integrity error is valid only when the *L4I* bit in the *Status* field is set. It is active if L4 processing fails (TCP checksum or UDP checksum or SCTP CRC). Packets with L4 integrity error are posted to host memory regardless of the store bad packet setting (*FCTRL.SBP*). In case of VXLAN or NVGRE packets, this relates to the internal L4 header.
- **FCEOF(11) / IPE(11)** — This bit has multiplexed functionality. FCoE packets are indicated as such in the *Packet Type* field in the Rx descriptor.

| Non-FCoE Packet                                                                                                                                             | FCoE Packet                                                                                                                                                                           |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IPE</b> (IPv4 checksum error) is described in <a href="#">Section 7.1.5</a> . In case of VXLAN or NVGRE packets, this relates to the internal IP header. | FC EOF Exception ( <b>FCEOF</b> ). This bit indicates unexpected EOF or SOF flags. The specific error is defined by the <i>FCEOF</i> bit in the extended status previously described. |

#### PKT\_LEN (16-bit offset 32, 2nd line)

PKT\_LEN holds the number of bytes posted to the packet buffer. The length covers the data written to a receive buffer including posted CRC bytes (if any). Software must read multiple descriptors to determine the complete length for packets that span multiple receive buffers. If *SRCTL.DESCTYPE* = 2 (advanced descriptor header splitting) and the buffer is not split because the header is bigger than the allocated header buffer, this field reflects the size of the data written to the data buffer (header + data).

When short packets are padded, the *PKT\_LEN* does not include the padding, so that the software device driver can detect the location of a potential time stamp in the packet.

When a time stamp is added (*TSIP* bit is set), the *PKT\_LEN* includes the timestamp size (+8).

#### VLAN Tag (16-bit offset 48, 2nd line)

This field is described in the legacy descriptor format in [Section 7.1.5](#). The VLAN tag is set to 0x0000 even if a VLAN tag is present if the *PFQDE.HIDE\_VLAN* bit is set for the queue.

### 7.1.5.3 Receive Descriptor Fetching

The X550 implements a fetch-by-demand mechanism for descriptor fetch. Descriptors are not fetched in advance, but rather fetched after a packet is received. Such a strategy eliminates the need to store descriptors on-die for each and every descriptor queue in anticipation for packet arrival.

### 7.1.5.4 Receive Descriptor Write-Back

The X550 writes back the receive descriptor immediately following the packet write into system memory. It is therefore possible for a single descriptor to be written at a time into memory. However, if aggregation occurs during descriptor fetch (see [Section 7.1.5.3](#)), the descriptors fetched in the aggregated operation are written back in a single write-back operation. In Receive Coalescing (RSC), all the descriptors except the last one are written back when they are completed. This does not have to be on packet boundaries but rather when the next descriptor of the same RSC is fetched. See [Section 7.10.5.1](#) for more on RSC.

**Note:** Software can determine if a packet has been received only by checking the receive descriptor *DD* bit in memory. Checking through *DD* bits (and not by checking the receive head pointer in *RDH/RDL* registers) eliminates a potential race condition: all descriptor data is posted internally prior to incrementing the head register and a read of the head register could potentially pass the descriptor waiting inside the X550.

## 7.1.5.5 Receive Descriptor Queue Structure

Figure 7-11 shows the structure of each of the receive descriptor rings. Note that each ring uses a contiguous memory space.

**Figure 7-11. Receive Descriptor Ring Structure**

Software inserts receive descriptors by advancing the tail pointer(s) to refer to the address of the entry just beyond the last valid descriptor. This is accomplished by writing the descriptor tail register(s) with the offset of the entry beyond the last valid descriptor. The X550 adjusts its internal tail pointer(s) accordingly. As packets arrive, they are stored in memory and the internal head pointer(s) is increased by the X550.

When RSC is not enabled, the visible (external) head pointer(s) reflect the internal ones. On any receive queue that enables RSC, updating the external head pointer might be delayed until interrupt assertion. When the head pointer(s) is equal to the tail pointer(s), the queue(s) is empty. The X550 stops storing packets in system memory until software advances the tail pointer(s), making more receive buffers available.

**Figure 7-12. Descriptors and Memory Rings**

The X550 writes back used descriptors just prior to advancing the head pointer(s). Head and tail pointers wrap back to base when the number of descriptors corresponding to the size of the descriptor ring have been processed.

The receive descriptor head and tail pointers reference to 16-byte blocks of memory. Shaded boxes in Figure 7-12 represent descriptors that have stored incoming packets but have not yet been recognized by software. Software can determine if a receive buffer is valid by reading descriptors in memory rather than by I/O reads. Any descriptor with a *DD* bit set has been used by the hardware, and is ready to be processed by software.

**Note:** The head pointer points to the next descriptor that is to be written back. At the completion of the descriptor write-back operation, this pointer is increased by the number of descriptors written back. Hardware owns all descriptors between [head... tail]. Any descriptor not in this range is owned by software.

The receive descriptor rings are described by the following registers:

- **Receive Descriptor Base Address registers (RDBA)** — This register indicates the start of the descriptor ring buffer; this 64-bit address is aligned on a 128-byte boundary and is stored in two consecutive 32-bit registers. Hardware ignores the lower 7 bits.
- **Receive Descriptor Length registers (RDLEN)** — This register determines the number of bytes allocated to the circular buffer. This value must be a multiple of 128 (the maximum cache line size). Since each descriptor is 16 bytes in length, the total number of receive descriptors is always a multiple of 8.
- **Receive Descriptor Head registers (RDH)** — This register holds a value that is an offset from the base, and indicates the in-progress descriptor. There can be up to 64K-8 descriptors in the circular buffer. Hardware maintains a shadow copy that includes those descriptors completed but not yet stored in memory.

Software can determine if a packet has been received by either of two methods: reading the *DD* bit in the receive descriptor field or by performing a Programmed I/O read of the Receive Descriptor Head register. Checking the descriptor *DD* bit in memory eliminates a potential race condition. All descriptor data is written to the I/O bus prior to incrementing the head register, but a read of the head register could pass the data write in systems performing I/O write buffering. Updates to receive descriptors use the same I/O write path and follow all data writes. Consequently, they are not subject to the race.

- **Receive Descriptor Tail registers (RDT)** — This register holds a value that is an offset from the base, and identifies the location beyond the last descriptor hardware can process. This is the location where software writes the first new descriptor.

If software statically allocates buffers, and uses a memory read to check for completed descriptors, it simply has to zero the status byte in the descriptor to make it ready for re-use by hardware. This is not a hardware requirement, but is necessary for performing an in-memory scan. This is relevant only to legacy descriptors.

All the registers controlling the descriptor rings behavior should be set before receive is enabled, apart from the tail registers which are used during the regular flow of data.

### 7.1.5.5.1 Low Receive Descriptors Threshold

As previously described, the size of the receive queues is measured by the number of receive descriptors. During run time, software processes descriptors and upon completion of descriptors, increments the Receive Descriptor Tail registers. At the same time, the hardware may post new received packets incrementing the Receive Descriptor Head registers for each used descriptor.

The number of usable (free) descriptors for the hardware is the distance between the Tail and Head registers. When the tail reaches the head, there are no free descriptors and further packets might be either dropped or block the receive FIFO. To avoid this situation, the X550 might generate a low latency interrupt (associated to the relevant Rx queue) once there are less equal free descriptors than specified by a low level threshold. The threshold is defined in 64 descriptors granularity per queue in the `SRRCTL[n].RDMTS` field.

## 7.1.6 Receive Offloads

### 7.1.6.1 Header Splitting

#### 7.1.6.1.1 Purpose

This feature consists of splitting a packet header to a different memory space. This helps the host to fetch headers only for processing: headers are posted through a regular snoop transaction to be processed by the host CPU. It is recommended to perform this transaction with TPH enabled (see [Section 7.5](#)).

The X550's support for header split is controlled by the *DESCTYPE* field of the Split Receive Control registers (SRRCTL). The following modes exist in both split and non-split modes:

- 000b: Legacy mode — Legacy descriptors are used, headers and payloads are not split.
- 001b: Advanced mode, no split — Advanced descriptors are in use, header and payload are not split.
- 010b: Advanced mode, header split — Advanced descriptors are in use, header and payload are split to different buffers.
- 101b: Advanced mode, split always — Advanced descriptors are in use, header and payload are split to different buffers. If no split is done, the first part of the packet is stored in the header buffer.

The X550 uses packet splitting when the SRRCTL[n].*DESCTYPE* is greater than one.

#### 7.1.6.1.2 Description

**Figure 7-13. Header Splitting Diagram**

The physical address of each buffer is written in the *Buffer Addresses* fields:

- The packet buffer address includes the address of the buffer assigned to the packet data.
- The header buffer address includes the address of the buffer that contains the header information. The receive DMA module stores the header portion of the received packets into this buffer.

The sizes of these buffers are statically defined in the SRRCTL[n] registers:

- The *BSIZEPACKET* field defines the size of the buffer for the received packet.
- The *BSIZEHEADER* field defines the size of the buffer for the received header. If header split is enabled, this field must be configured to a non-zero value. The X550 only writes the header portion into the header buffer. The header size is determined by the options enabled in the PSRTYPE registers.

When header split is selected, the packet is split only on selected types of packets. A bit exists for each option in PSRTYPE[n] registers, so several options can be used in conjunction. If one or more bits are set, the splitting is performed for the corresponding packet type. See [Section 8.2.2.8.17](#) for details on the possible header types supported. In virtualization mode, a separate PSRTYPE register is provided per pool up to the number of pools enabled. In non-virtualization mode, only PSRTYPE[0] is used.

Rules regarding header split:

- Packets that have headers bigger than 1023 bytes are not split.
- The header of a fragmented IPv6 packet is defined until the *Fragment* extension header.
- Header split must not be used in a queue used for a FCoE large receive.
- An IP in IP packet (such as any combination of IPv4 and IPv6 tunneling) is not split. Not relevant for NVGRE and VXLAN packets
- Packet header cannot span across buffers, therefore, the size of the header buffer must be larger than any expected header size. In case of header split mode (SRRCTL.DESCTYPE = 010b), a packet with a header larger than the header buffer is not split.
- If an IPsec header is present in the receive packet, the following rules apply:
  - IPsec packets handled in the X550 always include IPsec header in a split done at IP boundary.
  - IPsec packets handled in software must never do header split.

[Table 7-24](#) lists the behavior of the X550 in the different modes.

**Table 7-24. Behavior in Header Split Modes**

| DESCTYPE | Condition                                                     | SPH | HBO <sup>1</sup> | PKT_LEN <sup>2</sup>              | HDR_LEN <sup>2</sup>     | Header and Payload DMA <sup>3</sup>                                           |
|----------|---------------------------------------------------------------|-----|------------------|-----------------------------------|--------------------------|-------------------------------------------------------------------------------|
| Split    | 1. Header can't be decoded                                    | 0   | 0                | Min (packet length, buffer size)  | 0x0                      | Header + Payload (+ TimeStamp) (+ Padding) -> Packet Buffer                   |
|          | 2. Header <= BSIZEHEADER and Payload > 0                      | 1   | 0                | Min (payload length, buffer size) | Header size              | Header -> Header Buffer<br>Payload (+ TimeStamp) (+ Padding) -> Packet Buffer |
|          | 3. Header <= BSIZEHEADER and Payload = 0 (Header only packet) | 1   | 0                | 0                                 | Header size              | Header (+ TimeStamp) (+ Padding) -> Header Buffer <sup>4</sup>                |
|          | 4. Header > BSIZEHEADER                                       | 1   | 1                | Min (packet length, buffer size)  | Header size <sup>5</sup> | Header + Payload (+ TimeStamp) -> Packet Buffer                               |

Table 7-24. Behavior in Header Split Modes (Continued)

| DESCTYPE                         | Condition                                                   | SPH | HBO <sup>1</sup> | PKT_LEN <sup>2</sup>                                | HDR_LEN <sup>2</sup>     | Header and Payload DMA <sup>3</sup>                                           |
|----------------------------------|-------------------------------------------------------------|-----|------------------|-----------------------------------------------------|--------------------------|-------------------------------------------------------------------------------|
| Split – always use header buffer | 1. Header can't be decoded and packet length <= BSIZEHEADER | 0   | 0                | 0x0                                                 | Packet length            | Header + Payload (+ TimeStamp) (+ Padding) -> Header Buffer                   |
|                                  | 2. Header cannot be decoded and packet length > BSIZEHEADER | 0   | 0                | Min (packet length – BSIZEHEADER, data buffer size) | BSIZEHEADER              | Header + Payload (+ TimeStamp) -> Header + Packet Buffers <sup>5</sup>        |
|                                  | 3. Header <= BSIZEHEADER                                    | 1   | 0                | Min (payload length, data buffer size)              | Header Size              | Header -> Header Buffer<br>Payload (+ TimeStamp) (+ Padding) -> Packet Buffer |
|                                  | 4. Header > BSIZEHEADER                                     | 1   | 1                | Min (packet length – BSIZEHEADER, data buffer size) | Header Size <sup>6</sup> | Header + Payload (+ TimeStamp) -> Header + Packet Buffer                      |

1. HBO is set to 1b if the header size is bigger than BSIZEHEADER and zero otherwise.
2. PKT\_LEN and HDR\_LEN includes optionally added time stamp if TSIP bit is set and does not include padding added by the device.
3. Partial means up to BSIZEHEADER.
4. Even if there is no payload at all and there is a timestamp in the packet - the timestamp is considered as an 8 bytes payload and is written to the packet buffer.
5. If the packet spans more than one descriptor, only the header buffer of the first descriptor is used.
6. HDR\_LEN does not reflect the actual data size stored in the header buffer. It reflects the header size determined by the parser.

### 7.1.6.2 Receive Packet Timestamp in Buffer

The X550 supports adding an optional tailored header appended to the end of the packet in the receive buffer. The tailored header includes a 64-bit timestamp composed of the packet reception time measured in the SYSTIMEL (Low DW) and SYSTIMEH (High DW) registers (See [Section 7.7.3.2](#) for further information on SYSTIMEL/H operation). The timestamp starts right at the end of the packet (after the last byte). It is sent as {SYSTIMEH, SYSTEML} - most significant byte first (closest to packet).

PKT\_LEN and HDR\_LEN includes optionally added time stamp.

When the TSAUXC.DISABLE\_SYSTIME bit is cleared and the TSYNCRXCTL.TSIP\_UP\_EN is set for the UP in the packet (or TSYNCRXCTL.TSIP\_UT\_EN for un-tagged packets), packets received that meet the TSYNCRXCTL.TYPE are time-stamped. A packet that was time stamped is reported as follows:

- Place a 64-bit timestamp, indicating the time a packet was received by the MAC, appended at the end of the received packet within the receive buffer.
- Set the TSIP bit in the RDESC.STATUS field of the last receive descriptor.

**Notes:** Even if TSYNCRXCTL.TYPE=100b (timestamp all packets), FCoE DDP packets do not have a timestamp.

When packets are coalesced, the timestamp reflects the reception time of the last coalesced fragment, unless the packet is a pure ACK packet, in which case, the timestamp is of the first packet.

### 7.1.6.3 Receive Checksum Offloading

The X550 supports the offloading of three receive checksum calculations: the fragment checksum, the IPv4 header checksum, and the TCP/UDP checksum.

For supported packet/frame types, the entire checksum calculation can be offloaded to the X550. The X550 calculates the IPv4 checksum and indicates a pass/fail indication to software via the *IPv4 Checksum Error* bit (RDESC.IPE) in the *ERROR* field of the receive descriptor. Similarly, the X550 calculates the TCP or UDP checksum and indicates a pass/fail condition to software via the *TCP/UDP Checksum Error* bit (RDESC.TCPE). For NVGRE or VXLAN packets, the *IPE* and *TCPE* bits relates to the inner IP/TCP header. The outer IPv4 checksum is also checked and a pass/fail indication is indicated to software via the *Outer IPv4 Checksum Error* bit (OUTERIPER). These error bits are valid when the respective status bits indicate the checksum was calculated for the packet (RDESC.IPCS, RDESC.L4CS, and RDESC.OUTERIPCS respectively).

Similarly, if RFCTL.IPV6\_DIS and RFCTL.IP6XSUM\_DIS are cleared to zero, the X550 calculates the TCP or UDP checksum for IPv6 packets. It then indicates a pass/fail condition in the *TCP/UDP Checksum Error* bit (RDESC.TCPE).

**Note:** Only Ethernet II frames are supported (no checksum support for SNAP packets).

**Table 7-25. Supported Receive Checksum Capabilities**

| Packet Type                                                                                                                                                                                                                                                                                                                  | Hardware IP Checksum Calculation                                     | Hardware TCP/UDP Checksum Calculation |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------|---------------------------------------|
| IP header's protocol field contains a protocol # other than TCP or UDP.                                                                                                                                                                                                                                                      | Yes                                                                  | No                                    |
| IPv4 + TCP/UDP packets.                                                                                                                                                                                                                                                                                                      | Yes                                                                  | Yes                                   |
| IPv6 + TCP/UDP packets.                                                                                                                                                                                                                                                                                                      | No (N/A)                                                             | Yes                                   |
| IPv4 packet has IP options (IP header is longer than 20 bytes).                                                                                                                                                                                                                                                              | Yes                                                                  | Yes                                   |

| VXLAN: <ul style="list-style-type: none"> <li>Inner IPv4 packet</li> <li>Inner IPv6 packet</li> </ul> | Yes (Inner and outer)<br>Yes (outer) | Yes (inner only) <sup>1</sup><br>Yes (inner only) |

1. The outer UDP header of VXLAN packets do not use a checksum.

### 7.1.6.4 SCTP Receive Offload

If a receive packet is identified as SCTP, the X550 checks the CRC32 checksum of this packet and identifies this packet as SCTP. Software is notified of the CRC check via the *L4I* and *L4E* bits in the *Extended Status* field and *Extended Error* field in the Rx descriptor. The detection of an SCTP packet is indicated via the *SCTP* bit in the *Packet Type* field of the Rx descriptor. SCTP CRC uses the CRC32c polynomial as follows (0x11EDC6F41):

$$X_{32}+X_{28}+X_{27}+X_{26}+X_{25}+X_{23}+X_{22}+X_{20}+X_{19}+X_{18}+X_{14}+X_{13}+X_{11}+X_{10}+X_9+X_8+X_6+X_0$$

The checker assumes the following SCTP packet format.

**Table 7-26. SCTP Header**

|                       |                                  |                                  |                                  |
|-----------------------|----------------------------------|----------------------------------|----------------------------------|
| <div>01234567</div>   | <div>1</div> <div>89012345</div> | <div>2</div> <div>67890123</div> | <div>3</div> <div>45678901</div> |
| Source Port           |                                  | Destination Port                 |                                  |

| CRC Checksum (CRC32c) |                                  |                                  |                                  |
| Chunks 1..n           |                                  |                                  |                                  |

### 7.1.6.5 Receive UDP Fragmentation Checksum

The X550 might provide a receive fragmented UDP checksum offload for IPv4 non-tunneled packets. The *RXCSUM.PCSD* bit should be cleared and the *RXCSUM.IPPCSE* bit should be set to enable this mode.

The following table lists the outcome descriptor fields for the following incoming packets types.

| Incoming Packet Type                                                       | Fragment Checksum                                                                                                                | UDPV                                          | UDPCS / L4CS                                     |
|----------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------|--------------------------------------------------|
| Non-IP packet                                                              | 0                                                                                                                                | 0                                             | 0                                                |
| IPv6 packet                                                                | 0                                                                                                                                | 0                                             | Depends on transport<br>UDP: 1 / 1<br>TCP: 0 / 1 |
| Non fragmented IPv4 packet                                                 |                                                                                                                                  |                                               |                                                  |
| Fragmented IPv4 with protocol = UDP, first fragment (UDP protocol present) | The unadjusted 1's complement checksum of the IP payload if Checksum in packet header is different than zero and zero otherwise. | 1 if the UDP header checksum is valid (not 0) | 0 / 0                                            |

| Incoming Packet Type                                                                                       | Fragment Checksum                                              | UDPV                                          | UDPCS / L4CS |
|------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|-----------------------------------------------|--------------|
| Fragmented IPv4, when not first fragment                                                                   | The unadjusted 1's complement checksum of the IP payload       | 1                                             | 0 / 0        |
| Fragmented IPv4 with protocol = UDP, first fragment (UDP protocol present) within a VXLAN or NVGRE packet. | The unadjusted 1's complement checksum of the inner IP payload | 1 if the UDP header checksum is valid (not 0) | 1 / 0        |
| Fragmented IPv4 when not first fragment within a VXLAN or NVGRE packet.                                    | The unadjusted 1's complement checksum of the inner IP payload | 0                                             | 1 / 0        |

**Note:** When the driver computes the 16-bit ones complement sum on the incoming packets of the UDP fragments, it should expect a value of 0xFFFF.

## 7.1.7 Receive Statistics

### 7.1.7.1 General Rules

- All Statistics registers are cleared on read. In addition, they stick at 0xFF...F when the maximum value is reached.
- For the receive statistics it should be noted that a packet is indicated as received if it passes the device filters and is placed into the packet buffer memory. A packet does not have to be DMA'd to host memory to be counted as received.
- Due to divergent paths between interrupt-generation and logging of relevant statistics counts, it might be possible to generate an interrupt to the system for a noteworthy event prior to the associated statistics count actually being increased. This is extremely unlikely due to expected delays associated with the system interrupt-collection and ISR delay, but might be an explanation for interrupt statistics values that do not quite make sense. Hardware guarantees that any event noteworthy of inclusion in a statistics count is reflected in the appropriate count within 1  $\mu$ s; a small time-delay prior to reading the statistics might be required to avoid a potential mismatch between and interrupt and its cause.
- If RSC is enabled, statistics are collected before RSC is applied to the packets.
- All byte (octet) counters composed of 2 registers can be fetched by two consecutive 32-bit accesses while reading the Low 32-bit register first or a single 64-bit access.
- All receive statistic counters count the packets and bytes before coalescing by the RSC logic or FCoE DDP logic.
- All receive statistic counters in the Filter unit (listed below) might count packets that might be dropped by the packet buffer or receive DMA. Same comment is valid for the byte counters associated with these packet counters: PRC64, PRC127, PRC255, PRC511, PRC1023, PRC1522, BPRC, MPRC, GPRC, RXNFGPC, RUC, ROC.

## 7.1.7.2 Receive Statistics Hierarchy

The following diagram describes the relations between the packet flow and the different statistic counters.

Figure 7-14. Receive Flow Statistics

## 7.2 Transmit Functionality

### 7.2.1 Packet Transmission

Transmit packets are made up of data buffers in host memory that are indicated to hardware by pointer and length pairs. These pointer and length pairs are named as transmit descriptors that are stored in host memory as well.

Software prepares memory structures for transmission by assembling a list of descriptors. It then indicates this list to hardware for updating the on-chip transmit tail pointer. Hardware transmits the packet only after it has completely fetched all packet data from host memory and deposited it into the on-chip transmit FIFO. This store and forward scheme enables hardware-based offloads such as TCP or UDP checksum computation, and many other ones detailed in this document while avoiding any potential PCIe under-runs.

#### 7.2.1.1 Transmit Storage in System Memory

A packet (or multiple packets in transmit segmentation) can be composed of one or multiple buffers. Each buffer is indicated by a descriptor. Descriptors of a single packet are consecutive, while the first one points to the first buffer and the last one points to the last buffer (see [Figure 7-15](#)). The following rules must be kept:

- Address alignment of the data buffers can be on any byte boundary.
- Data buffers of any transmitted packet must include at least the 12 bytes of the source and destination Ethernet MAC Addresses as well as the 2 bytes of the *Type/Len* field.
- A packet (or multiple packets in transmit segmentation) can span any number of buffers (and their descriptors) up to a limit of 40 minus *WTHRESH* minus 2 (see [Section 7.2.3.3](#) for Tx Ring details and [Section 7.2.3.5.1](#) for *WTHRESH* details). For best performance it is recommended to minimize the number of buffers as possible.

**Figure 7-15. Tx Packet in Host Memory**

## 7.2.1.2 Transmit Path in the X550

The transmit path in the X550 consists of the following stages:

- Descriptor plane
  - The X550 maintains a set of 128 on-die descriptor queues. Each queue is associated with a single descriptor ring in system memory. See [Section 7.2.3.3](#) for more details on the Tx descriptor rings. Each on-die descriptor queue contains up to 40 descriptors to achieve the desired performance.
  - A fetch mechanism loads Tx descriptors from the descriptor rings in system memory to the respective descriptor queues in the X550. A descriptor fetch arbiter determines the order in which descriptors are fetched into the various on-die descriptor queues. See [Section 7.2.3.4](#) for more details on the fetch mechanism.
  - An arbitration scheme determines the order in which descriptors are processed and requests are generated for data reads. These requests load packet data from system memory into a set of Tx packet buffers. The arbitration mechanism varies with configuration and is described in [Section 7.8](#).
  - Once a packet has been fetched into a packet buffer, status is (optionally) written back into system memory. See [Section 7.2.3.5](#) for more details.
- Packet plane (data plane)
  - Packet data is stored in up to eight packet buffers. The number and size of packet buffers vary with the mode of operation and is described in [Section 7.2.1.2.2](#).
  - If more than a single packet buffer is enabled, an arbitration scheme determines the order in which packets are taken out of the packet buffers and sent to the MAC for transmission. The arbitration mechanism is described in [Section 7.8](#).

### 7.2.1.2.1 Tx Queues Assignment

The X550 supports a total of 128 queues per LAN port. Each Tx queue is associated with a packet buffer and the association varies with the operational mode. The following mechanisms impact the association of the Tx queues. These are described briefly in this section, and in full details in separate sections:

- **Virtualization (VT)** — In a virtualized environment, DMA resources are shared between more than one software entity (operating system and/or device driver). This is done through allocation of transmit descriptor queues to virtual partitions (VMM, IOVM, VMs, or VFs). Allocation of queues to virtual partitions is done in sets of queues of the same size, called queue pools, or **pools**. A pool is associated with a single virtual partition. Different queues in a pool can be associated with different packet buffers. For example, in a DCB system, each of the queues in a pool might belong to a different TC and therefore to a different packet buffer. The PFVFTE register contains a bit per VF. When the bit is set to 0b, packet transmission from the VF is disabled. When set to 1b, packet transmission from the VF is enabled.
- **DCB** — DCB provides QoS through priority queues, priority flow control, and congestion management. Queues are classified into one of several (up to eight) Traffic Classes (TCs). Each TC is associated with a single unique packet buffer.
- **Transmit fanout** — A single descriptor queue might be enough for a given functionality. For example, in a VT system, a single Tx queue can be allocated per VM. However, it is often the case that the data rate achieved through a single buffer is limited. This is especially true with 10 GbE, and traffic needs to be divided into several Tx queues to reach the desired data rate. Therefore, multiple queues might be provided for the same functionality.

Table 7-27 lists the queuing schemes. Scheme selection is done via the MTQC register.

**Table 7-27. Tx Queuing Schemes**

| VT  | DCB | Queues Allocation                                                                                                                                                                     | Packet Buffers Allocation                                                  |
|-----|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| No  | No  | A single set of 64 queues is assigned to a single packet buffer. Queues 64...127 should not be used.                                                                                  | A single packet buffer for all traffic                                     |
| No  | Yes | Eight TCs mode — allocation of 32-32-16-16-8-8-8-8 queues for TC0-TC1-...- TC7, respectively.<br>Four TCs mode — allocation of 64-32-16-16 queues for TC0-TC1-...- TC3, respectively. | A separate packet buffer is allocated to each TC (total of four or eight). |
| Yes | No  | 32 pools x 4 queues, or<br>64 pools x 2 queues                                                                                                                                        | A single packet buffer for all traffic.                                    |
| Yes | Yes | 16 pools x 8 TCs, or<br>32 pools x 4 TCs                                                                                                                                              | A separate packet buffer is allocated to each TC (total of four or eight). |

**Note:** Software can use any number of queues per each TC or per each pool within the allocated ranges previously described by disabling any unused queue.

**Note:** Programming MTQC must be done only during the init phase, while software must also set RTTDCS.ARBDIS before configuring MTQC and then clear RTTDCS.ARBDIS afterwards.

**Table 7-28. Queues, Pools, and TCs programming**

| Device Setting (MTQC) |        |             | Device Functionality      |                      |
|-----------------------|--------|-------------|---------------------------|----------------------|
| DCB_ena               | VT_Ena | NUM_TC_OR_Q | Total Number of Tx Queues | TC & Pools           |
| 0                     | 0      | 00          | 64                        | -                    |
| <> 0                  | <> 0   | 00          | Non valid configuration   |                      |
| 0                     | 0      | <> 00       | Non valid configuration   |                      |
| 1                     | 0      | 01          | N/A                       |                      |
| 1                     | 0      | 10          | 128                       | TC0 — TC3            |
| 1                     | 0      | 11          | 128                       | TC0 — TC7            |
| 0                     | 1      | 01          | 128                       | 64 pools             |
| 0                     | 1      | 10          | 128                       | 32 pools             |
| 0                     | 1      | 11          | N/A                       |                      |
| 1                     | 1      | 01          | N/A                       |                      |
| 1                     | 1      | 10          | 128                       | TC0 — TC3 & 32 pools |
| 1                     | 1      | 11          | 128                       | TC0 — TC7 & 16 pools |

Allocating descriptor queues to VFs uses a consistent indexing over the different Tx queuing schemes. The most significant bits of the queue index represent the VF index, and the least significant bits are either the TC index or are used by software to dispatch traffic according to a Transmit Side Scaling (TSS) algorithm — similar to RSS in the Rx path.

The Tx queue numbers associated with the TCs are listed in the following tables: [Table 7-29](#) and [Table 7-30](#).

**Table 7-29. Tx Queues Indexing When VT-on**

| VT Mode                      | Allocation of Queue Index Bits According to |   |   |   |    |          |     |
|------------------------------|---------------------------------------------|---|---|---|----|----------|-----|
|                              | 6                                           | 5 | 4 | 3 | 2  | 1        | 0   |
| 64 VFs + TSS                 | VF or pool (63..0)                          |   |   |   |    |          | TSS |
| 32 VFs + TSS <i>or</i> 4 TCs | VF or pool (31..0)                          |   |   |   |    | TSS / TC |     |
| 16 VFs + 8 TCs               | VF (15..0)                                  |   |   |   | TC |          |     |

**Table 7-30. Tx Queues Indexing When VT-off and DCB-on**

| TC Mode | TCn | # of Qs | Queues Attached to TCn |
|---------|-----|---------|------------------------|
| 4 TCs   | TC0 | 64      | 0xxxxxx                |
|         | TC1 | 32      | 10xxxxx                |
|         | TC2 | 16      | 110xxxx                |
|         | TC3 | 16      | 111xxxx                |
| 8 TCs   | TC0 | 32      | 00xxxxx                |
|         | TC1 | 32      | 01xxxxx                |
|         | TC2 | 16      | 100xxxx                |
|         | TC3 | 16      | 101xxxx                |
|         | TC4 | 8       | 1100xxx                |
|         | TC5 | 8       | 1101xxx                |
|         | TC6 | 8       | 1110xxx                |
|         | TC7 | 8       | 1111xxx                |

**Note:** “x” refers to both 0 or 1, and is used by software to dispatch Tx flows via TSS algorithm.

### 7.2.1.2.2 Tx Packet Buffers

As previously described, the following modes exist for the X550 packet buffers:

- A single 160 KB packet buffer that serves all Tx descriptor queues, leading to one single (or no) TC enabled, TC0
- Four 40 KB packet buffers, one per enabled TC, leading to four TCs, TC0 to TC3
- Eight 20 KB packet buffers, one per enabled TC, leading to eight TCs, TC0 to TC7

The size of the Tx packet buffer(s) is programmed via the TXPBSIZE registers, one register per TC. Null-sized packet buffer corresponds to a disabled TC.

**Note:** Setting the packet buffers’ size leads to a different partition of a shared internal memory and must be done during boot, prior to communicating, and followed by a software reset.

The size of all of the packet buffers together is 160 KB.  
 The X550 can have any number of packet buffers less than or equal to 8.  
 The packet buffer size is specified for each packet buffer in the  
 TXPBSIZE registers.

**Figure 7-16. Tx Packet Buffers**

### 7.2.1.2.3 Tx Arbitration Schemes

There are basically four Tx arbitration schemes, one per each combination of the DCB and Virtualization (VT) enabled/disabled modes. They are configured via the MTQC.MTQE register field.

#### 7.2.1.2.3.1 DCB-on/VT-on

When both DCB and virtualization are enabled, queues are allocated to the packet buffers in a fixed manner, the same number of queues per each TC. Two DCB modes are supported, four TCs or eight TCs mode, according to coherent configuration made in registers TXPBSIZE and MTQC.

#### Descriptor Plane Arbiters and Schedulers:

- **Rate-Scheduler** — Once a frame has been fetched out from a rate-limited queue, the next time another frame could be fetched from that queue is regulated by the rate-scheduler. In the meantime, the queue is considered as if it was empty (such as switched-off) for the subsequent arbitration layers.
- **VM Weighted Round Robin Arbiter** — Descriptors are fetched out from queues attached to the same TC in a frame-by-frame weighted round-robin manner, while taking into account any limitation as previously described. Weights or credits allocated to each queue are configured via the RTTDT1C register. Bandwidth unused by one queue is reallocated to the other queues within the TC, proportionally to their relative bandwidth shares. TC bandwidth limitation is distributed across all the queues attached to the TC, proportionally to their relative bandwidth shares. Details on

weighted round-robin arbiter between the queues can be found in [Section 7.6.2.3](#). It is assumed traffic is dispatched across the queues attached to a same TC in a straightforward manner, according to the VF to which it belongs.

- **TC Weighted Strict Priority Arbiter** — Descriptors are fetched out from queues attached to different TCs in a frame-by-frame weighted strict-priority manner. Weights or credits allocated to each TC are configured via RTTDT2C registers. Bandwidth unused by one TC is reallocated to the others, proportionally to their relative bandwidth shares. Link bandwidth limitation is distributed across all the TCs, proportionally to their relative bandwidth shares. Details on weighted strict-priority arbiter between the TCs can be found at [Section 7.6.2.3](#). It is assumed (each) driver dispatches traffic across the TCs according to the 802.1p *User Priority* field inserted by the operating system and according to a user priority-to-TC Tx mapping table.

#### Packet Plane Arbiters:

- **TC Weighted Strict Priority Arbiter** — Packets are fetched out from the different packet buffers in a frame-by-frame weighted strict-priority manner. Weights or credits allocated to each TC (such as to each packet buffer) are configured via RTTPT2C registers, with the same allocation done at the descriptor plane. Bandwidth unused by one TC and link bandwidth limitation is distributed over the TCs as in the descriptor plane. Details on weighted strict-priority arbiter between the TCs can be found in [Section 7.6.2.3](#).
- **Priority Flow Control** packets are inserted with strict priority over any other packets.
- **Manageability** packets are inserted with strict priority over data packets from the same TC, with respect to the bandwidth allocated to the concerned TC. TCs that belong to manageability packets are controlled by MNGTXMAP.MAP.

**Figure 7-17. Transmit Architecture DCB-on/VT-on — Eight TCs Mode**

**Note:** Replicating TC arbiters before and after the packet buffers is required to provide arbitration whether PCI bandwidth is smaller or greater than the link bandwidth, respectively.

### 7.2.1.2.3.2 DCB-on/VT-off

When DCB is enabled and virtualization disabled, queues are allocated to the packet buffers in a fixed manner according to the number of TCs. Two DCB modes are supported, four TCs or eight TCs mode, according to coherent configuration made in registers TXPBSIZE and MTQC. In Figure 7-18, eight TCs mode is shown.

- The unique difference with the DCB-on/VT-on arbitration scheme previously described is that the VM weighted round-robin arbiters are degenerated into simple frame-by-frame round-robin arbiters across the queues attached to the same TC. It is assumed driver dispatches traffic across the queues attached to a same TC according to hashing performed on MAC destination addresses. This is aimed to minimize crosstalk between rate-limited and non-rate-limited flows.

Figure 7-18. Transmit Architecture DCB-on/VT-off — Eight TCs Mode

### 7.2.1.2.3.3 DCB-off/VT-on

When DCB is disabled and virtualization enabled, all the 128 queues are allocated to a single packet buffer PB(0). Queues are grouped into 32 or 64 pools of 4 or 2 queues, respectively. The number of queue pools corresponds to the number of VFs exposed. Queues are attached to pools according to consecutive indexes

- For the 32 pools case, queues 0, 1, 2, 3 are attached to VF0, queues 4, 5, 6, 7 are attached to VF1, and so forth up to VF31.
- For the 64 pools case, queues 0 and 1 are attached to VF0, queues 2 and 3 are attached to VF1, and so forth up to VF63.

### Descriptor Plane Arbiters:

- **Descriptor Queues Round Robin Arbiter** — Descriptors are fetched out from the internal descriptor queues attached to the same pool in a frame-by-frame round-robin manner. It is assumed driver dispatches traffic across the queues of a same pool according to some Transmit Side Scaling (TSS) algorithm similarly to what is done by hardware in the Rx path with RSS.
- **VM Weighted Round Robin Arbiter** — Descriptors are fetched out from queues attached to different pools in a frame-by-frame weighted round-robin manner. Weights or credits allocated to a pool are those allocated for the lowest queue of the pool via the RTTDT1C register. Bandwidth unused by one pool is reallocated to the others proportionally to their relative bandwidth shares. Link bandwidth limitation is distributed across all the pools, proportionally to their relative bandwidth shares. Details on weighted round-robin arbiter between the pools can be found in [Section 7.6.2.3](#).

### Packet Plane Arbiter:

- **Manageability** packets are inserted with strict priority over data packets.

Figure 7-19. Transmit Architecture DCB-off/VT-on — 32 VFs

#### 7.2.1.2.3.4 DCB-off/VT-off

When both DCB and virtualization features are disabled, a single set of up to 64 queues is allocated to a single packet buffer PB(0).

##### Descriptor Plane Arbiter:

- **Descriptor Queues Round Robin Arbiter** — Descriptors are fetched out from the internal descriptor queues in a frame-by-frame round-robin manner. It is assumed driver dispatches traffic across the queues according to some TSS algorithm similarly to what is done by hardware in the Rx path with RSS.

##### Packet Plane Arbiter:

- **Manageability** packets are inserted with strict priority over data packets.

Figure 7-20. Transmit Architecture DCB-off/VT-off

## 7.2.2 Transmit Contexts

The X550 provides hardware checksum offload and TCP segmentation facilities. These features enable TCP and UDP packet types to be handled more efficiently by performing additional work in hardware, thus reducing the software overhead associated with preparing these packets for transmission. Part of the parameters used to control these features are handled through contexts.

A context refers to a set of parameters providing a particular offload functionality. These parameters are loaded by unique descriptors named transmit context descriptors. A transmit context descriptor is identified by the *DTYP* field (described later in this section) equals to 0x2.

The X550 supports two contexts for each of its 128 transmit queues. The *IDX* bit contains an index to one of these two contexts. Each advanced data descriptor that uses any of the advanced offloading features must refer to a context by the *IDX* field.

Contexts can be initialized with a transmit context descriptor and then used for a series of related transmit data descriptors. Software can use these contexts as long lived ones, while one of the two contexts is used for checksum offload and the other one for transmit segmentation detailed in the following sections. The contexts should be modified when new offload parameters are required.

## 7.2.3 Transmit Descriptors

### 7.2.3.1 Introduction

The X550 supports legacy descriptors and advanced descriptors.

Legacy descriptors are intended to support legacy drivers, to enable fast platform power up and to facilitate debug. The legacy descriptors are recognized as such based on *DEXT* bit (see the sections that follow). Legacy descriptors are not supported together with DCB, virtualization, and IPsec. These modes are recognized by a dedicated enable bit for each.

In addition, the X550 supports two types of advanced transmit descriptors:

1. Advanced transmit context descriptor, *DTYP* = 0010b
2. Advanced transmit data descriptor, *DTYP* = 0011b

**Note:** *DTYP* = 0000b and 0001b are reserved values.

The transmit data descriptor (both legacy and advanced) points to a block of packet data to be transmitted. The advanced transmit context descriptor does not point to packet data. It contains control/context information that is loaded into on-chip registers that affect the processing of packets for transmission. The following sections describe the descriptor formats.

## 7.2.3.2 Transmit Descriptors Formats

### 7.2.3.2.1 Notations

This section defines the structure of descriptors that contain fields carried over the network. At the moment, the only relevant field is the *VLAN Tag* field.

The rule for VLAN tag is to use network ordering (also called big endian). It appears in the following manner in the descriptor:

**Table 7-31. VLAN Tag**

| Byte address N + 1 -> first byte on the wire<br>Bit 7 — first on the wire <- Bit 0 |     | Byte address N -> second byte on the wire<br>Bit 7 -> last on the wire — Bit 0 |              |
|------------------------------------------------------------------------------------|-----|--------------------------------------------------------------------------------|--------------|
| PRI (3 bits)                                                                       | DEI | VID (4 bits)                                                                   | VID (8 bits) |

### 7.2.3.2.2 Legacy Transmit Descriptor Format

To select legacy mode operation, bit 29 (*TDESC.DEXT*) should be set to 0b. In this case, the descriptor format is defined as listed in Table 7-32. Address and length must be supplied by software on all descriptors. Bits in the command byte are optional, as are the *CSO*, and *CSS* fields.

**Table 7-32. Transmit Descriptor (TDESC) Layout — Legacy Mode**

|   | 63                    | 48 | 47  | 40 | 39   | 36 | 35  | 32 | 31  | 24 | 23  | 16 | 15     | 0 |
|---|-----------------------|----|-----|----|------|----|-----|----|-----|----|-----|----|--------|---|
| 0 | Buffer Address [63:0] |    |     |    |      |    |     |    |     |    |     |    |        |   |
| 8 | VLAN                  |    | CSS |    | Rsvd |    | STA |    | CMD |    | CSO |    | Length |   |

**Table 7-33. Transmit Descriptor Write-Back Format — Legacy Mode**

|   | 63       | 48 | 47  | 40 | 39   | 36 | 35  | 32 | 31       | 24 | 23  | 16 | 15     | 0 |
|---|----------|----|-----|----|------|----|-----|----|----------|----|-----|----|--------|---|
| 0 | Reserved |    |     |    |      |    |     |    | Reserved |    |     |    |        |   |
| 8 | VLAN     |    | CSS |    | Rsvd |    | STA |    | CMD      |    | CSO |    | Length |   |

#### Buffer Address (64) and Length (16)

The buffer address is a byte-aligned address. Length (*TDESC.LENGTH*) specifies the length in bytes to be fetched from the buffer address provided. The maximum length associated with a single descriptor is 15.5 KB while the total frame size must meet the maximum supported frame size. There is no limitation for the minimum buffer size.

**Note:** Descriptors with zero length (null descriptors) transfer no data. Null descriptors might appear only between packets and must have their *EOP* bits set.

#### Checksum Offset and Start — CSO (8) and CSS (8)

A *Checksum Offset* (*TDESC.CSO*) field indicates where, relative to the start of the packet, to insert a TCP checksum if this mode is enabled. A *Checksum Start* (*TDESC.CSS*) field indicates where to begin computing the checksum. Note that *CSO* and *CSS* are meaningful only in the first descriptor of a packet.

Both *CSO* and *CSS* are in units of bytes. These must both be in the range of data provided to the device in the descriptor. This means for short packets that are padded by software, *CSO* and *CSS* must be in the range of the un-padded data length, not the eventual padded length (64 bytes).

*CSO* must be set to the location of TCP or UDP checksum in the packet. *CSS* must be set to the beginning of the IP header or the L4 (TCP/UDP) header. Checksum calculation is not done if *CSO* or *CSS* are out of range. This occurs if (*CSS* > length) OR (*CSO* > length - 1).

For the 802.1Q header, the offset values depend on the VLAN insertion enable bit — the *VLE* bit. If they are not set (VLAN tagging included in the packet buffers), the offset values should include the VLAN tagging. If these bits are set (VLAN tagging is taken from the packet descriptor), the offset values should exclude the VLAN tagging.

Hardware does not add the 802.1q Ethertype or the VLAN field following the 802.1Q Ethertype to the checksum. So for VLAN packets, software can compute the values to back out only on the encapsulated packet rather than on the added fields.

**Note:** UDP checksum calculation is not supported by the legacy descriptor because the legacy descriptor does not support the translation of a checksum result of 0x0000 to 0xFFFF needed to differentiate between an UDP packet with a checksum of zero and an UDP packet without checksum.

Because the *CSO* field is eight bits wide, it puts a limit on the location of the checksum to 255 bytes from the beginning of the packet.

**Note:** *CSO* must be larger than *CSS*.

Software must compute an offsetting entry to back out the bytes of the header that should not be included in the TCP checksum and store it in the position where the hardware computed checksum is to be inserted.

Hardware adds the checksum at the byte offset indicated by the *CSO* field. Checksum calculations are for the entire packet starting at the byte indicated by the *CSS* field. The byte offset is counted from the first byte of the packet fetched from host memory.

#### Command Byte — CMD (8)

The CMD byte stores the applicable command and has the fields listed in [Table 7-34](#).

**Table 7-34. Transmit Command (TDESC.CMD) Layout**

| 7   | 6   | 5    | 4   | 3  | 2  | 1    | 0   |
|-----|-----|------|-----|----|----|------|-----|
| RSV | VLE | DEXT | RSV | RS | IC | IFCS | EOP |

- *RSV (bit 7)* — Reserved.
- *VLE (bit 6) - VLAN Packet Enable* — When set to 1b, *VLE* indicates that the packet is a VLAN packet and hardware adds the VLAN header to the Tx packet. The VLAN Ethertype is taken from *DMATXCTL.VT* and the 802.1q VLAN tag is taken from the *VLAN* field in the Tx descriptor. See [Section 7.4.5](#) for details about double VLAN.

**Table 7-35. VLAN Tag Insertion Decision Table for VLAN Mode Enabled**

| VLE | Action                                                                                                                                                                                     |
|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | Send generic Ethernet packet.                                                                                                                                                              |
| 1   | Send 802.1Q packet; the <i>Ethernet Type</i> field comes from the <i>VET</i> field of the <i>VLNCTRL</i> register and the VLAN data comes from the <i>VLAN</i> field of the Tx descriptor. |

**Note:** This table is relevant only if *PFVMVIR.VLANA* = 00b (use descriptor command) for the queue.

- *DEXT (bit 5) - Descriptor Extension* — Zero for legacy mode.
- *RSV (bit 4)* — Reserved.

- **RS (bit 3) - Report Status** — RS signals hardware to report the DMA completion status indication as well as triggering ITR. Hardware indicates a DMA completion by setting the *DD* bit in the transmit descriptor when *TDWBAL[n].HEAD\_WB\_EN* = 0b or by Head Write-back if *HEAD\_WB\_EN* = 1b (see [Section 7.2.3.5.2](#)). The *RS* bit is permitted only on descriptors that has the *EOP* bit set (last descriptor of a packet).

**Note:** Software should not set the *RS* bit when *TXDCTL.WTHRESH* is greater than zero. Instead, the hardware reports the DMA completion according to the *WTHRESH* rules (explained in [Section 7.2.3.5.1](#)). This note is relevant only for descriptor write back while in head write-back mode. *WTHRESH* must also be set to zero.

When *TXDCTL.WTHRESH* = zero, software must set the *RS* bit on the last descriptor of every packet.

There are some exceptions for descriptor completion indication in head write-back mode. For more details see [Section 7.2.3.5.2](#).

- **IC (bit 2) - Insert Checksum** — Hardware inserts a checksum at the offset indicated by the *CSO* field if the *Insert Checksum* bit (*IC*) is set.
- **IFCS (bit 1) - Insert FCS** — When set, hardware appends the MAC FCS at the end of the packet. When cleared, software should calculate the FCS for proper CRC check. There are several cases in which software must set *IFCS* as follows:
  - Transmitting a short packet while padding is enabled by the *HLREG0.TXPADEN* bit.
  - Checksum offload is enabled by the *IC* bit in the *TDESC.CMD*.
  - VLAN header insertion enabled by the *VLE* bit in the *TDESC.CMD* or by the *PFVMVIR.VLANA* fields.
  - E-tag insertion enabled by the *PFVMVIR.TAGA* fields.
  - TSO or TCP/IP checksum offload using a context descriptor.
  - IPsec offload is requested.

**Note:** TSO and IPsec offload are relevant only to advanced Tx descriptors.

- **EOP (bit 0) - End of Packet** — A packet can be composed of multiple buffers (each of them indicated by its own descriptor). When *EOP* is set, it indicates the last descriptor making up the packet.

**Note:** *VLE*, *IFCS*, and *IC* fields should be set in the first descriptor of a packet. The *RS* bit can be set only on the last descriptor of a packet. The *DEXT* bit must be set to zero for all descriptors. The *EOF* bit is meaningful in all descriptors.

#### STA (4) — Transmitted.Status

#### DD (bit 0) — Descriptor Done Status

This bit provides a status indication that the DMA of the buffer has completed. Software might re-use descriptors with the *DD* bit set and any other descriptors processed by the hardware before this one. The other bits in the *STA* field are reserved.

#### Rsvd — Reserved (4)

#### VLAN (16)

The *VLAN* field is used to provide the 802.1q/802.1ac tagging information. The *VLAN* field is qualified on the first descriptor of each packet when the *VLE* bit is set to 1b. The *VLAN* field is provided in network order and is meaningful in the first descriptor of a packet. See [Section 7.2.3.2.1](#) for more details.

**Table 7-36. VLAN Field (TDESC.VLAN) Layout**

|     |     |      |    |   |
|-----|-----|------|----|---|
| 15  | 13  | 12   | 11 | 0 |
| PRI | DEI | VLAN |    |   |

### 7.2.3.2.3 Advanced Transmit Context Descriptor

**Table 7-37. Transmit Context Descriptor (TDESC) Layout — (Type = 0010)**

|   |           |    |            |    |       |          |                |         |                             |      |          |     |    |        |       |                   |                  |   |
|---|-----------|----|------------|----|-------|----------|----------------|---------|-----------------------------|------|----------|-----|----|--------|-------|-------------------|------------------|---|
|   | 63        | 56 | 55         | 48 | 47    | 42       | 41             | 32      | 31                          | 16   | 15       | 9   | 8  | 0      |       |                   |                  |   |
| 0 | TUNNELLEN |    | OUTERIPLEN |    | FCoEF |          | IPsec SA Index |         |                             | VLAN |          |     |    | MACLEN |       | IPLEN/<br>HEADLEN |                  |   |
| 8 | MSS       |    |            |    | L4LEN |          | RS<br>V        | ID<br>X | Reserved<br>must be<br>0x3F |      | DE<br>XT | RSV |    | DTYP   | TUCMD |                   | IPsec<br>ESP_LEN |   |
|   | 63        |    | 48         | 47 | 40    | 39<br>37 | 36             | 35      | 30                          | 29   | 28       | 24  | 23 | 20     | 19    | 9                 | 8                | 0 |

#### IPLEN/HEADLEN (9)

- IPLEN** (for IP packets) — This field holds the value of the IP header length for the IP checksum offload feature. If an offload is requested, *IPLEN* must be greater than or equal to 20, and less than or equal to 511. For IP tunnel packets (IPv4-IPv6) *IPLEN* must be defined as the length of the two IP headers. The hardware is able to offload the L4 checksum calculation while software should provide the IPv4 checksum. For IPsec packets, it is the sum of IP header length plus IPsec header length.
- HEADLEN** (for FCoE packets) — This field indicates the size (in bytes) of the FCoE frame header. The frame header includes the MAC header, optional VLAN and FCoE header(s) as shown in [Figure 7-46](#). *HEADLEN* is meaningful only if transmit FCoE offload is enabled by setting the *FCoE* bit in the *TUCMD* field. *HEADLEN* that matches [Figure 7-46](#) equals 56 for packets without FC extended headers.

#### MACLEN (7)

- For non-FCoE packets:

This field indicates the length of the MAC header. When an offload is requested, one of the *TSE* bits (in the advanced transmit data descriptor) or *IXSM* bit or *TXSM* bit are set, *MACLEN* must be larger than or equal to 14, and less than or equal to 127. This field should include only the part of the L2 header supplied by the driver and not the parts added by hardware. The following table lists the value of *MACLEN* in the different cases.

| Regular VLAN        | Extended tag | MACLEN |
|---------------------|--------------|--------|
| By hardware or none | None         | 14     |
| By hardware or none | VLAN         | 18     |
| By hardware or none | E-tag        | 22     |
| By software         | None         | 18     |
| By software         | VLAN         | 22     |
| By software         | E-tag        | 26     |

- For FCoE packets:

This field is a byte offset to the last Dword of the FCoE header (supplied by the driver) that includes the SOF flag. The FC frame header starts four bytes after the *MACLEN* as shown in [Figure 7-46](#). The *MACLEN* that matches [Figure 7-46](#) equals 28.

#### VLAN (16)

This field contains the 802.1Q VLAN tag to be inserted in the packet during transmission. This VLAN tag is inserted when a packet using this context has its *DCMD.VLE* bit is set. This field should include the entire 16-bit *VLAN* field including DEI and priority fields as listed in [Table 7-36](#).

Note that the *VLAN* field is provided in network order. See [Section 7.2.3.2.1](#).

#### IPsec SA IDX (10)

IPsec SA Index — If an IPsec offload is requested for the packet (*IPSEC* bit is set in the advanced Tx data descriptor), indicates the index in the SA table where the IPsec *KEY* and *SALT* are stored for that flow.

#### FCoEF (6)

- *EOF (bits 1:0)* — End of frame delimiter index (see [Section 7.11.2.4](#) for details).
- *ORIE (bit 4)* — Orientation relative to the last frame in an FC sequence (see [Section 7.11.2.4](#) for details).
- *SOF (bit 2)* — Start of frame delimiter index (see [Section 7.11.2.3](#) for details).
- *ORIS (bit 5)* — Orientation relative to the first frame in an FC sequence (see [Section 7.11.2.3](#) for details).
- *PARINC (bit 3)* — When this bit is set, hardware relates to the *PARAM* field in the FC header as relative offset. In this case, hardware increments the *PARAM* field in TSO by an MSS value on each transmitted packet of the TSO. Software should set the *PARINC* bit when it sets the *Relative Offset Present* bit in the *F\_CTL*.

#### OUTERIPLEN (8)

This field holds the value of the outer IP header length.

#### TUNNELLEN (8)

This field holds the length value of the tunnel headers including the inner L2 header.

#### IPS\_ESP\_LEN(9)

Size of the ESP trailer and ESP ICV appended by software. Meaningful only if the *IPSEC\_TYPE* bit is set in the *TUCMD* field and to single send packets for which the *IPSEC* bit is set in their advanced Tx data descriptor.

#### TUCMD (11)

- *RSV (bit 10-7)* — Reserved.
- *FCoE (bit 6)* — This bit defines the context descriptor and the associated data descriptors as FCoE frame type. See [Section 7.11.2](#) for a description of the offload provided by the hardware while transmitting a single frame and TSO.
- *Reserved (bit 5:4)* — Reserved.
- *L4T (bit 3:2)* — L4 Packet TYPE (00: UDP; 01: TCP; 10: SCTP; 11: RSV). Should be set to 11b for FCoE packets.
- *IPV4(bit 1)* — IP Packet Type: When 1b, IPv4; when 0b, IPv6.

#### DTYP (4)

This field is always 0010b for this type of descriptor.

#### RSV(1)

Reserved.

#### DEXT (1)

Descriptor Extension (one for advanced mode).

#### Reserved (6)

Reserved.

#### IDX (1)

The context descriptor is posted to a context table in hardware. There are two context tables per queue. The IDX is the index of the context tables.

**Note:** Because the X550 supports only two context descriptors per queue, the two MS bits are reserved and should be set to 0b.

#### RSV(1)

Reserved.

#### L4LEN(8)

This field holds the layer 4 header length. If *TSE* is set, this field must be greater than or equal to 8 and less than or equal to 64. Otherwise, this field is ignored. Note that for UDP segmentation the L4 header size equals 8 and for TCP segmentation (with no TCP options) it equals 20.

#### MSS (16)

This field controls the Maximum Segment Size. This specifies the maximum protocol payload segment sent per frame, not including any header. MSS is ignored when *DCMD.TSE* is not set.

### 7.2.3.2.3.1 TCP/UDP Segmentation

The total length of each frame (or segment) excluding Ethernet CRC as follows. Note that the last packet of a TCP segmentation might be shorter.

$$\text{MACLEN} + 4(\text{if VLE set}) + [4, 8, 14, \text{ or } 16] + \text{OUTERIPLEN} + \text{TUNNELLEN} + \text{IPLN} + \text{L4LEN} + \text{MSS} + [\text{PADLEN} + 18] \text{ (if ESP packet)}$$

PADLEN ranges from zero to three in Tx and is the content of the *ESP Padding Length* field that is computed when offloading ESP in cipher blocks of 16 bytes (AES-128) with respect to the following alignment formula:

$$[\text{L4LEN} + \text{MSS} + \text{PADLEN} + 2] \text{ modulo}(4) = 0$$

For a single send the *IPS\_ESP\_LEN* equals to *PADLEN* + 18.

**Note:** The headers lengths must meet the following:  $\text{MACLEN} + \text{IPLN} + \text{L4LEN} \leq 512$

### 7.2.3.2.3.2 FCoE Segmentation

The total length of each frame (or segment) excluding Ethernet CRC is equal to:

$$\text{MACLEN} + 4(\text{if VLE set}) + [4, 8, 14, \text{or } 16] + 8 (\text{FC CRC} + \text{EOF})$$

**Note:** For FCoE packets, the maximum segment size defines the FC payload size in all packets but the last one, which can be smaller.

The context descriptor requires valid data only in the fields used by the specific offload options. [Table 7-38](#) lists the required valid fields according to the different offload options.

**Table 7-38. Valid Fields by Offload Option**

|                  | Context Fields -> | FCoE | FCoEF | VLAN | MACLEN | OUTERIPLEN/TUNNELLEN | IPLEN/HEADLEN | L4LEN |  | IPv4 | L4T      | Encryption | IPSECTYPE | SAIDX | ESP_LEN | MSS | QCNTLEN | CC (data descriptor) |
|------------------|-------------------|------|-------|------|--------|----------------------|---------------|-------|--|------|----------|------------|-----------|-------|---------|-----|---------|----------------------|
| Required Offload | VLAN insertion    |      |       | yes  |        |                      |               |       |  |      |          |            |           |       |         |     | yes     |                      |
|                  | IPv4 XSUM         | n/a  | n/a   |      | yes    |                      | yes           |       |  | 1    |          |            |           |       |         |     | yes     | 0                    |
|                  | L4 XSUM           | n/a  | n/a   |      | yes    |                      | yes           |       |  |      | yes      |            |           |       |         |     | yes     | 0                    |
|                  | TCP/UDP Seg       | n/a  | n/a   |      | yes    |                      | yes           | yes   |  | yes  | yes      |            |           |       |         | yes | yes     | 0                    |
|                  | FCoE CRC          | yes  | yes   |      | yes    |                      | yes           | n/a   |  | n/a  | Yes (11) | n/a        | n/a       | n/a   | n/a     |     | yes     | 1                    |
|                  | FCoE Seg          | yes  | yes   |      | yes    |                      | yes           | n/a   |  | n/a  | Yes (11) | n/a        | n/a       | n/a   | n/a     | yes | yes     | 1                    |
|                  | IPsec ESP         | n/a  | n/a   |      | yes    |                      | yes           |       |  | yes  |          | yes        | yes       | yes   | yes     |     | yes     | 1                    |
|                  | IPsec AH          | n/a  | n/a   |      | yes    |                      | yes           |       |  | yes  |          | yes        | yes       | yes   | yes     |     | yes     | 1                    |
|                  | Tunnel XSUM       | n/a  | n/a   |      | yes    | yes                  | yes           |       |  |      | yes      |            |           |       |         |     |         | 1                    |
|                  | Tunnel Seg        | n/a  | n/a   |      | yes    | yes                  | yes           | yes   |  | yes  | yes      |            |           |       |         | yes | yes     | 1                    |
|                  | Tx switch         | n/a  | n/a   |      | yes    |                      | yes           | yes   |  | yes  | yes      | n/a        | n/a       | n/a   | n/a     |     | yes     | 1                    |

**Note:** All fields that are not used in the context descriptor must be set to zero.

### 7.2.3.2.4 Advanced Transmit Data Descriptor

**Table 7-39. Advanced Transmit Data Descriptor Read Format**

|   | 63            | 46 | 45 | 40 | 39    | 38 | 36  | 35  | 32   | 31   | 24  | 23 | 20     | 19 | 18     | 17 | 16 | 15 | 0 |
|---|---------------|----|----|----|-------|----|-----|-----|------|------|-----|----|--------|----|--------|----|----|----|---|
| 0 | Address[63:0] |    |    |    |       |    |     |     |      |      |     |    |        |    |        |    |    |    |   |
| 8 | PAYLEN        |    |    |    | POPTS | CC | IDX | STA | DCMD | DTYP | MAC |    | TUNNEL |    | DTALEN |    |    |    |   |

**Table 7-40. Advanced Transmit Data Descriptor Write-back Format**

|   | 63  | 36 | 35 | 32 | 31  | 0   |
|---|-----|----|----|----|-----|-----|
| 0 | RSV |    |    |    |     |     |
| 8 | RSV |    |    |    | STA | RSV |

#### Address (64)

This field holds the physical address of a data buffer in host memory, which contains a portion of a transmit packet. This field is meaningful in all descriptors.

#### DTALEN (16)

This field holds the length in bytes of data buffer at the address pointed to by this specific descriptor. This field is meaningful in all descriptors. The maximum length is 16 KB with no limitations on the minimum size. Refer to the comment on descriptors with zero length described in the sections that follow.

#### TUNNEL (2)

- *Tunnel Type (bit 0):*  
0 = VXLAN  
1 = NVGRE
- *OUTERIPCS (bit 1) - Outer IP checksum enable* — Indicates this is a tunnel packet and that the *OUTERIPLEN/TUNNELLEN* parameters in the context descriptor are valid.

#### MAC (2)

This field is meaningful on the first descriptor of the packet(s).

- *Reserved (bit 0)* — Reserved.
- *1588 (bit 1)* — IEEE1588 time stamp packet.

#### DTYP (4)

0011b for advanced data descriptor. DTYP should be valid in all descriptors of the packet(s).

#### DCMD (8)

- *TSE (bit 7) - Transmit Segmentation Enable* — This bit indicates a TCP or FCoE segmentation request. When *TSE* is set in the first descriptor of a TCP or FCoE packet, hardware must use the corresponding context descriptor to perform segmentation.  
**Note:** It is recommended that *HLREG0.TXPADEN* be enabled when *TSE* is used since the last frame can be shorter than 60 bytes — resulting in a bad frame.
- *VLE (bit 6) - VLAN Packet Enable* — This bit indicates that the packet is a VLAN packet (hardware must add the VLAN Ethertype and an 802.1q VLAN tag to the packet).

- **DEXT (bit 5) - Descriptor Extension** — This bit must be one to indicate advanced descriptor format (as opposed to legacy).
- **Rsv (bit 4)** — Reserved.
- **RS (bit 3) - Report Status** — See the description in the legacy transmit descriptor in [Section 7.2.3.2.2](#).
- **Rsv (bit 2)** — Reserved.
- **IFCS (bit 1) - Insert FCS** — When this bit is set, the hardware appends the MAC FCS at the end of the packet. When cleared, software should calculate the FCS for proper CRC check. There are several cases in which software must set IFCS as follows:
  - Transmitting a short packet while padding is enabled by the `HLREG0.TXPADEN` bit.
  - Checksum offload is enabled by the either `IC`, `TXSM` or `IXSM` bits in the `TDESC.DCMD`.
  - VLAN header insertion enabled by the `VLE` bit in the `TDESC.DCMD`.
  - FC CRC (FCoE) offload is enabled by the `FCoE` bit in the transmit context descriptor.
  - TCP or FCoE segmentation offload enabled by the `TSE` bit in the `TDESC.DCMD`.
- **EOP (bit 0) - End of Packet** — A packet might be composed of multiple buffers (each of them is indicated by its own descriptor). When `EOP` is set, it indicates the last descriptor making up the packet. In transmit segmentation (explained later on in this section) the `EOP` flag indicates the last descriptor of the last packet of the segmented transmission.

**Note:** `TSE`, `VLE` and `IFCS` fields should be set in the first descriptor of the packet(s). The `RS` bit can be set only on the last descriptor of the packet. The `EOP` bit is valid in all descriptors. The `DEXT` bit must be set to 1b for all descriptors.

Descriptors with zero length, transfer no data. If the `RS` bit in the command byte is set, the `DD` field in the status word is not written when hardware processes them.

#### STA (4)

- **Rsv (bit 3:1)** — Reserved.
- **DD (bit 0) - Descriptor Done** — The `DD` bit provides a status indication that the DMA of the buffer has completed. Software might re-use descriptors with the `DD` bit set, and any other descriptors processed by hardware before this one. In TSO, the buffers that include the TSO header are used multiple times during transmission and special considerations should be made as described in [Section 7.2.4.2.2](#).

#### IDX (3)

This field holds the index into the hardware context table to indicate which of the two per-queue contexts should be used for this request. If no offload is required and the `CC` bit is cleared, this field is not relevant and no context needs to be initiated before the packet is sent. See [Table 7-38](#) for details of which packets requires a context reference. This field is relevant only on the first descriptor of the packet(s).

#### CC (1)

**Check Context bit** — When set, a Tx context descriptor indicated by `IDX` index should be used for this packet(s). The `CC` bit should be set in the following cases:

1. Non-zero `QCNTLEN` field is required (defined in the context descriptor).
2. Any FCoE offload is required.
3. Tx switching is enabled (including anti-spoof checks).

## POPTS (6)

- *Rsv (bit 5:2)* — Reserved.
- *TXSM (bit 1) - Insert TCP/UDP Checksum* — When set to 1b, the L4 checksum must be inserted. In this case, TUCMD.LP4 indicates whether the checksum is TCP or UDP or SCTP. When DCMD.TSE is set, TXSM must be set to 1b. If this bit is set, the packet should at least contain a TCP header.
- *IXSM (bit 0) - Insert IP Checksum* — This field indicates that IP checksum must be inserted. In IPv6 mode, it must be reset to 0b. If DCMD.TSE and TUCMD.IPV4 are set, IXSM must be set to 1b. If this bit is set, the packet should at least contain an IP header.

This field is relevant only on the first descriptor of the packet(s).

## PAYLEN (18)

*PAYLEN* indicates the size (in byte units) of the data buffer(s) in host memory for transmission.

In a single-send packet, *PAYLEN* defines the entire packet size fetched from host memory. It does not include the fields that hardware adds such as: optional VLAN tagging, the FCoE trailer containing the FC CRC and EOF (For FCoE packets) and Ethernet CRC or Ethernet padding.

When IPsec offload is enabled, the *PAYLEN* field does not include the ESP trailer added by hardware.

In TSO (regardless if it is transmitted on a single or multiple packets), the *PAYLEN* defines the protocol payload size fetched from host memory.

- In TCP or UDP segmentation offload, *PAYLEN* defines the TCP/UDP payload size.
- In FCoE TSO offload, the *PAYLEN* field defines the FC payload size. It includes the FC option headers (if present) and the FC data payload but excludes the FCoE trailer containing the FC CRC and EOF.

This field is relevant only on the first descriptor of the packet(s). The minimum transmitted packet size excluding VLAN padding and CRC bytes is 17 and the *PAYLEN* size should meet this limitation. On a single-packet send, the maximum size of the *PAYLEN* is dictated by the maximum allowed packet size which is 15.5 KB. On TSO, the maximum *PAYLEN* can be up to  $2^{18}-1$ .

**Note:** When a packet spreads over multiple descriptors, all of the descriptor fields are valid only on the first descriptor of the packet, except for *RS* and *EOP* bits, which are set on the last descriptor of the packet.

## 7.2.3.3 Transmit Descriptor Ring

The transmit descriptor ring structure (shown in [Figure 7-21](#)) uses a contiguous memory space. A set of four registers (described later in this section) maintain the transmit descriptor ring in the host memory. Hardware maintains internal circular queues of 64 descriptors per queue to hold the descriptors that were fetched from the software ring.

Descriptors handed to hardware should not be manipulated by software until hardware completes its processing. It is indicated by advancing the head pointer beyond these descriptors.

**Figure 7-21. Transmit Descriptor Ring Structure**

The transmit descriptor ring is defined by the following registers:

- **Transmit Descriptor Base Address register (TDBA 0-127)** — This register indicates the start address of the descriptor ring buffer in the host memory; this 64-bit address is aligned on a 128-byte boundary and is stored in two consecutive 32-bit registers. Hardware ignores the lower 7 bits.
- **Transmit Descriptor Length register (TDLEN 0-127)** — This register determines the number of bytes allocated to the circular buffer. This value must be 0 modulo 128.
- **Transmit Descriptor Head register (TDH 0-127)** — This register holds a value that is an offset from the base and indicates the in-progress descriptor. There can be up to 64 K minus 8 descriptors in the circular buffer. The transmit queue consists of the descriptors between the head and tail pointers. Transmission starts with the descriptor pointer by the head registers. When the DMA engine processes a descriptor, it might optionally write back the completed descriptor and then advance the head pointer. It then processes the next descriptor up to the point that the head pointer reaches the tail. Head equals tail means that the transmit queue in host memory is empty. Reading this register indicates the hardware progress to the software. All descriptors behind the head pointer and in front of tail register are owned by the software. The other descriptors are owned by the hardware and should not be modified by the software.
- **Transmit Descriptor Tail register (TDT 0-127)** — This register holds a value, which is an offset from the base, and indicates the location beyond the last descriptor hardware can process. Software adds new descriptors to the ring by writing descriptors in the circular buffer pointed by the tail pointer. The new descriptor(s) are indicated to hardware by updating the tail pointer one descriptor above the last added descriptor. Note that a single packet or TSO might be composed of multiple descriptors. The transmit tail pointer should never point to the middle of a packet or TSO, which might cause undesired software/hardware races.

Software might detect which packets have already been processed by hardware using the following:

- Read the TDH head register to determine which packets (those logically before the head) have been transferred to the on-chip FIFO or transmitted. This method is not recommended as races between the internal update of the head register and the actual write back of descriptors can occur.

- When head write back is enabled (TDWBAL[n].HEAD\_WB\_EN = 1b) software might read the image of the head pointer in host memory at the address defined by TDWBAH[n]/TDWBAL[n] pair. Hardware updates the head image in host memory by completed descriptors as described in [Section 7.2.3.5.2](#).
- When head write back is not enabled (TDWBAL[n].HEAD\_WB\_EN = 0b), software might track the DD bits in the descriptor ring. Descriptor write back is controlled by the RS bit and the WTHRESH setting as well as interrupt assertion.
- Issue an interrupt. An interrupt condition is generated each time a packet was transmitted or received and a descriptor was write back or transmit queue goes empty (EICR.RTxQ[0-19]). This interrupt can either be enabled or masked.

All of the registers controlling the descriptor rings behavior should be set before transmit is enabled.

### 7.2.3.4 Transmit Descriptor Fetching

The X550 fetches new descriptors as required for packet transmission depending on its on-die descriptor buffer state:

- **Fetch** — The on-chip descriptor buffer is empty or contains less descriptors than a complete packet.
  - A fetch starts as soon as any descriptors are made available (host writes to the tail pointer).
  - A request is issued for any available descriptors up to the size of the on-die buffer.
  - Once the sum of on-die descriptors and requested descriptors is more than required for a single packet, the buffer transitions to the pre-fetch state.
  - If several on-chip descriptor queues are empty simultaneously, queues are served in round robin arbitration except the queues indicated as strict priority, which are served first.
- **Pre-Fetch** — The on-chip descriptor buffer becomes almost empty while there are enough descriptors in the host memory.
  - The on-chip descriptor buffer is defined as almost empty if it contains less descriptors than the threshold defined by TXDCTL[n].PTHRESH.
  - The transmit descriptor contains enough descriptors if it includes more ready descriptors than the threshold defined by TXDCTL[n].HPTHRESH.
  - In pre-fetch mode, descriptors are fetched only after there are no other DMA activity of greater priority as: transmit descriptor fetch; status write-backs or packet data transfers).
  - A request is issued for any available descriptors up to the capacity of the on-die buffer.
  - If several on-chip descriptor queues are in this situation simultaneously, queues are served in round robin arbitration except the queues indicated as strict priority which are served first.
- **Idle** — Requests are not issued. This is the state reached when none of the previous states apply.

**Note:** Software must update the Tail register on packet boundaries. That is, the last valid descriptor might not be a context descriptor and must have the EOP bit set.

### 7.2.3.4.1 Transmit Descriptor Fetch and Write-back Settings

This section describes the settings of transmit descriptor thresholds. It relates to fetch thresholds described above as well as the write-back threshold (*WTHRESH*) when operating in descriptor write-back mode, which is described in [Section 7.2.3.5.1](#).

- Transmit descriptor fetch setting is programmed in the TXDCTL[n] register per queue. The default settings of *PTHRESH*, *HTHRESH* and *WTHRESH* are zero's.
- To reduce transmission latency, it is recommended to set the *PTHRESH* value as high as possible while the *HTHRESH* and *WTHRESH* as low as possible (down to zero).
- To minimize PCIe overhead the *PTHRESH* should be set as low as possible while *HTHRESH* and *WTHRESH* should be set as high as possible.
- The sum of *PTHRESH* plus *WTHRESH* must not be greater than the on-chip descriptor buffer size.
- Some practical rules:
  - CPU cache line optimization — Assume 'N' equals the CPU cache line divided by 16 (descriptor size). Then, to align descriptors pre-fetch to CPU cache line (in most cases), it is advised to set *PTHRESH* to the on-chip descriptor buffer size minus 'N' and *HTHRESH* to 'N'. To align descriptor write back to the CPU cache line it is advised to set *WTHRESH* to either 'N' or even 2 times 'N'. Note that partial cache line writes might significantly degrade performance. Therefore, it is highly recommended to follow this advice.
  - Minimizing PCIe overhead — As an example, setting *PTHRESH* to the on-chip descriptor buffer size minus 16 and *HTHRESH* to 16 minimizes the PCIe request and header overhead to ~20% of the bandwidth required for the descriptor fetch.
  - Minimizing transmission latency from tail update — Setting *PTHRESH* to the on-chip descriptor buffer size minus 'N' ('N' previously defined) while *HTHRESH* and *WTHRESH* to zero.
  - Threshold settings in DCB mode — Note that only values of *PTHRESH* equals on-chip descriptor buffer size minus 8 and *HTHRESH* equals 4 were thoroughly tested.

**Note:** As previously described, device setting is a trade-off between overhead (translated to performance) and latencies. It is expected that some level of optimization is done at software driver development phase. Customers who want better performance might need to adjust the threshold values according to the previous guidelines while optimizing to specific platform and targets.

### 7.2.3.5 Transmit Write Back

The X550 periodically updates software on its progress in processing transmit buffers. Two methods are described for doing so:

- Updating by writing back into the Tx descriptor.
- Update by writing to the head pointer in system memory.

### 7.2.3.5.1 Tx Descriptor Write Back

When the `TXDCTL[n].WTHRESH` equals zero, descriptors are written back for those descriptors with the *RS* bit set. When the `TXDCTL[n].WTHRESH` value is greater than zero, descriptors are accumulated until the number of accumulated descriptors equals the `TXDCTL[n].WTHRESH` value, then these descriptors are written back. Accumulated descriptor write back enables better use of the PCIe bus and memory bandwidth.

Any descriptor write back includes the full 16 bytes of the descriptor.

Descriptors are written back in one of three cases:

- `TXDCTL[n].WTHRESH = 0` and a descriptor that has *RS* set is ready to be written back.
- `TXDCTL[n].WTHRESH > 0` and `TXDCTL[n].WTHRESH` descriptors have accumulated.
- `TXDCTL[n].WTHRESH > 0` and the corresponding *EITR* counter has reached zero. The timer expiration flushes any accumulated descriptors and sets an interrupt event (*TXDW*).

An additional mode in which transmit descriptors are not written back at all and the head pointer of the descriptor ring is written instead is described in the following section.

### 7.2.3.5.2 Tx Head Pointer Write Back

In legacy hardware, transmit requests are completed by writing the *DD* bit to the transmit descriptor ring. This causes cache trash since both the driver and hardware are writing to the descriptor ring in host memory. Instead of writing the *DD* bits to signal that a transmit request is complete, hardware can write the contents of the descriptor queue head to host memory. The driver reads that memory location to determine which transmit requests are complete. To improve the performance of this feature, the driver needs to program TPH registers to configure which CPU processes each Tx queue.

The head pointer is reflected in a memory location that is allocated by software for each queue.

Rules for head pointer write back:

- Head write back occurs if `TDWBAL[n].HEAD_WB_EN` is set for this queue, and the *RS* bit is set in the Tx descriptor, following its corresponding data upload into packet buffer.
  - If the head write-back feature is enabled, software must set *WTHRESH* to 0x0 while only descriptors with the *RS* bit set, generate header write back.
  - Note that the head pointer write back does not hold transmission. Instead, if packets with the *RS* bit are transmitted fast enough, it might happen that the header pointer write back is not updated for each and every packet. In addition, it might happen that the head pointer write back might be updated up to descriptors that do not have the *RS* bit set. In such cases, hardware might report a completion of a descriptor that might not be the last descriptor in a TSO or even the last descriptor in a single packet.

The driver has control of this feature per queue through the `TDWBAL` and `TDWBAH` registers.

The low register's LSB hold the control bits.

- The *HEAD\_WB\_EN* bit enables activation of tail write back. In this case, no descriptor write back is executed.
- The 30 upper bits of this register hold the lowest 32 bits of the head write-back address, assuming that the two last bits are zero.

The high register holds the high part of the 64-bit address.

**Note:** Hardware writes a full Dword when writing this value, so software should reserve enough space for each head value and make sure the `TDBAL` value is Dword-aligned.

## 7.2.4 TCP and UDP Segmentation

Hardware TCP segmentation is one of the offloading options supported by the Windows\* and Linux\* TCP/IP stack. This is often referred to as Large Send offloading or TSO. This feature enables the TCP/IP stack to pass to the network device driver a message to be transmitted that is bigger than the Maximum Transmission Unit (MTU) of the medium. It is then the responsibility of the device driver and hardware to divide the TCP message into MTU size frames that have appropriate layer 2 (Ethernet), 3 (IP), and 4 (TCP) headers. These headers must include sequence number, checksum fields, options and flag values as required. Note that some of these values (such as the checksum values) are unique for each packet of the TCP message, and other fields such as the source IP Address is constant for all packets associated with the TCP message.

Similar to TCP segmentation, the X550 also provides a capability to offload UDP segmentation. Note that current UDP segmentation offload is not supported by any standard operating system.

**Note:** CRC appending (HLREG0.TXCRCEN) must be enabled in TCP / UDP segmentation mode because CRC is inserted by hardware.

Padding (HLREG0.TXPADEN) must be enabled in TCP / UDP segmentation mode, since the last frame might be shorter than 60 bytes — resulting in a bad frame if *TXPADEN* is disabled.

The offloading of these mechanisms to the device driver and the X550 saves significant CPU cycles. The device driver shares the additional tasks to support these options with the X550.

### 7.2.4.1 Assumptions and Restrictions

The following assumptions apply to the TCP / UDP segmentation implementation in the X550:

- To limit the internal cache dimensions, software is required to spread the header onto a maximum four descriptors, while still allowed to mix header and data in the last header buffer. This limitation stands for up to Layer 4 header included, and for IPv4 or IPv6 independently.
- The maximum size of a single TSO can be as large as defined by the *PAYLEN* field in the Tx data descriptor (such as up to 256 KB).
- The *RS* bit operation is not changed. Interrupts are set after data in the buffers pointed to by individual descriptors is transferred (DMA'ed) to hardware.
- SNAP packets are not supported for segmentation.
- IP in IP tunneled packets are not supported for offloading under TSO operation. VXLAN and NVGRE tunneled packets can be segmented.
- Software must enable the Ethernet CRC offload in the HLREG0.TXCRCEN register since CRC must be inserted by hardware after the checksum has been calculated.
- Software must initialize the appropriate checksum fields in the packet's header.

### 7.2.4.2 Transmission Process

The transmission process involves the following:

- The protocol stack receives from an application a block of data that is to be transmitted.
- The protocol stack calculates the number of packets required to transmit this block based on the MTU size of the media and required packet headers.

- The stack interfaces with the device driver and passes the block down with the appropriate header information: Ethernet, IP and TCP / UDP headers.
- The stack interfaces with the device driver and commands the driver to send the individual packet. The device driver sets up the interface to the hardware (via descriptors) for the TCP / UDP segmentation.
- The hardware transfers (DMA's) the packet data and performs the Ethernet packet segmentation and transmission based on offset and payload length parameters in the TCP/IP or UDP/IP context descriptor including:
  - Packet encapsulation
  - Header generation and field updates including IPv4/IPv6 and TCP/UDP checksum generation.
- The driver returns ownership of the block of data to the NOS when the hardware has completed the DMA transfer of the entire data block.

#### 7.2.4.2.1 TCP and UDP Segmentation Data Fetch Control

To perform TCP / UDP segmentation in the X550, the DMA must be able to fit at least one packet of the segmented payload into available space in the on-chip packet buffer. The DMA does various comparisons between the remaining payload and the packet buffer available space, fetching additional payload and sending additional packets as space permits.

The X550 enables interleaving between different TSO requests at an Ethernet packet level. In other words, the X550 might fetch part of a TSO from a queue, equivalent to one or more Ethernet packets, then transition to another queue and fetch the equivalent of one or more packets (TSO or not), then move to another queue (or the first queue), etc. The X550 decides on the order of data fetched based on its QoS requirements (such as bandwidth allocation and priority).

To enable interleaving between descriptor queues at the Ethernet frame resolution inside TSO requests, the frame header pointed by the so called header descriptors are re-read from system memory for every TSO segment (once per packet), storing in an internal cache only the header's descriptors instead of the header's content.

#### 7.2.4.2.2 TCP and UDP Segmentation Write-back Modes

TCP / UDP segmentation mode uses the buffers that contain the header of the packet multiple times (once for each transmitted segment). Software should guarantee that the header buffers are available throughout the entire TSO transmission. Therefore, software should not re-use any descriptors of the TSO header during the TSO transmission.

#### 7.2.4.3 TCP and UDP Segmentation Performance

Performance improvements for a hardware implementation of TCP / UDP segmentation offload include:

- The stack does not need to partition the block to fit the MTU size, saving CPU cycles.
- The stack only computes one Ethernet, IP, and TCP / UDP header per segment, saving CPU cycles.
- The stack interfaces with the device driver only once per block transfer, instead of once per frame.
- Larger PCI bursts are used, which improves bus efficiency (such as lowering transaction overhead).
- Interrupts are easily reduced to one per TCP / UDP message instead of one per packet.
- Fewer I/O accesses are required to command the hardware.

## 7.2.4.4 Packet Format

A TCP / UDP message can be as large as 256 KB and is generally fragmented across multiple pages in host memory. The X550 partitions the data packet into standard Ethernet frames prior to transmission. The X550 supports calculating the Ethernet, IP, TCP, and UDP headers, including checksum, on a frame-by-frame basis. For tunneled packets (NVGRE, VXLAN), The X550 also supports updating the outer IPv4 header.

**Table 7-41. TCP/IP and UDP/IP Packet Format Sent by Host**

| Pseudo Header |                        |           |         | Data                        |
|---------------|------------------------|-----------|---------|-----------------------------|
| Ethernet      | Optional tunnel header | IPv4/IPv6 | TCP/UDP | DATA (full TCP/UDP message) |

**Table 7-42. Packets Format Sent by Device**

|                         |                  |     |     |                         |                 |     |     |
|-------------------------|------------------|-----|-----|-------------------------|-----------------|-----|-----|
| Pseudo Header (updated) | Data (first MSS) | FCS | ... | Pseudo Header (updated) | Data (Next MSS) | FCS | ... |
|-------------------------|------------------|-----|-----|-------------------------|-----------------|-----|-----|

Frame formats supported by the X550 include:

- Ethernet 802.3
- IEEE 802.1Q VLAN (Ethernet 802.3ac)
- Ethernet Type 2
- NVGRE (see frame format in [Section A.2.5.1](#))
- VXLAN (see frame format in [Section A.2.5.2](#))
- IPv4 headers with options
- IPv6 headers with extensions
- TCP with options
- UDP with options

VLAN tag insertion can be handled by hardware.

**Note:** UDP (unlike TCP) is not a reliable protocol and fragmentation is not supported at the UDP level. UDP messages that are larger than the MTU size of the given network medium are normally fragmented at the IP layer. This is different from TCP, where large TCP messages can be fragmented at either the IP or TCP layers depending on the software implementation.

The X550 has the ability to segment UDP traffic (in addition to TCP traffic); however, because UDP packets are generally fragmented at the IP layer, the X550's segmentation capability might not be used in practice for UDP.

### 7.2.4.5 TCP and UDP Segmentation Indication

Software indicates a TCP/UDP segmentation transmission context to the hardware by setting up a TCP/IP or UDP/IP context transmit descriptor (see [Section 7.2.3](#)). The purpose of this descriptor is to provide information to the hardware to be used during the TCP / UDP segmentation offload process.

Setting the *TSE* bit in the *DCMD* field to one (in the data descriptor) indicates that this descriptor refers to the segmentation context (as opposed to the normal checksum offloading context). This causes the checksum offloading, packet length, header length, and maximum segment size parameters to be loaded from the descriptor into the device.

The TCP/UDP segmentation prototype header is taken from the packet data itself. Software must identify the type of packet that is being sent (IPv4/IPv6, TCP/UDP, other), calculate appropriate checksum off loading values for the desired checksums, and then calculate the length of the header that is pre-appended. The header can be up to 240 bytes in length.

Once the TCP/UDP segmentation context has been set, the next descriptor provides the initial data to transfer. This first descriptor(s) must point to a packet of the type indicated. Furthermore, the data it points to might need to be modified by software as it serves as the prototype header for all packets within the TC /UDP segmentation context. The following sections describe the supported packet types and the various updates that are performed by hardware. This should be used as a guide to determine what must be modified in the original packet header to make it a suitable prototype header.

The following summarizes the fields considered by the driver for modification in constructing the prototype header.

#### IP Header

For IPv4 headers:

- Identification field should be set as appropriate for first packet of send (if not already).
- Header checksums of inner and outer IP headers should be zeroed out unless some adjustment is needed by the driver.

#### TCP Header

- Sequence number should be set as appropriate for first packet of send (if not already).
- PSH, and FIN flags should be set as appropriate for LAST packet of send.
- TCP checksum should be set to the partial pseudo-header checksum as follows (there is a more detailed discussion of this in [Section 7.2.4.6](#)):

**Table 7-43. TCP Partial Pseudo-header Checksum for IPv4**

|                        |                     |      |
|------------------------|---------------------|------|
| IP Source Address      |                     |      |
| IP Destination Address |                     |      |
| Zero                   | Layer 4 Protocol ID | Zero |

**Table 7-44. TCP Partial Pseudo-header Checksum for IPv6**

|                                |             |
|--------------------------------|-------------|
| IPv6 Source Address            |             |
| IPv6 Final Destination Address |             |
| Zero                           |             |
| Zero                           | Next Header |

## UDP Header

- Checksum should be set as in TCP header, as previously explained.

The following sections describe the updating process performed by the hardware for each frame sent using the TCP segmentation capability.

### 7.2.4.6 Transmit Checksum Offloading with TCP and UDP Segmentation

The X550 supports checksum offloading as a component of the TCP/UDP segmentation off-load feature and as stand-alone capability. [Section 7.2.5](#) describes the interface for controlling the checksum off-loading feature. This section describes the feature as it relates to TCP/UDP segmentation.

The X550 supports IP and TCP header options in the checksum computation for packets that are derived from the TCP segmentation feature.

Two specific types of checksum are supported by the hardware in the context of the TCP/UDP segmentation off-load feature:

- IPv4 checksum
- TCP/UDP checksum

Each packet that is sent via the TCP/UDP segmentation off-load feature optionally includes the IPv4 checksum and/or the TCP/UDP checksum.

All checksum calculations use a 16-bit wide one's complement checksum. The checksum word is calculated on the outgoing data.

Refer to [Table 7-45](#) for the list of supported transmit checksums per packet type.

### 7.2.4.7 IP/TCP/UDP Header Updating

IP/TCP and IP/UDP header is updated for each outgoing frame based on the header prototype that hardware DMA's from the first descriptor(s). The checksum fields and other header information are later updated on a frame-by-frame basis. The updating process is performed concurrently with the packet data fetch.

The following sections define what fields are modified by hardware during the TCP/UDP segmentation process by the X550.

#### 7.2.4.7.1 TCP/IP/UDP Header for the First Frame

The hardware makes the following changes to the headers of the first packet that is derived from each TCP segmentation context.

##### Tunnel Header

When tunnel offload is enabled (*Tunnel* bit set in the descriptor) the outer IPv4 header is updated as follows:

- $IP\ Total\ Length = OUTERIPLEN + TUNNELLEN + IPLEN + L4LEN + MSS$
- Calculates the Outer IP Checksum

#### IPv4 Header

- $IP\ Total\ Length = MSS + L4LEN + IPLEN$
- Calculates the IP Checksum

#### IPv6 Header

- $Payload\ Length = MSS + L4LEN + IPV6\_HDR\_extension^1$

#### TCP Header

- Sequence Number: The value is the sequence number of the first TCP byte in this frame.
- The flag values of the first frame are set by logic AND function between the flag word in the pseudo header and the `DTXTCPFLGL.TCP_FLG_FIRST_SEG`. The default values of the `DTXTCPFLGL.TCP_FLG_FIRST_SEG` are set. The flags in a TSO that ends up as a single segment are taken from the in the pseudo header in the Tx data buffers as is.
- Calculates the TCP checksum.

#### UDP Header

- Calculates the UDP checksum.

### 7.2.4.7.2 TCP/IP Header for the Subsequent Frames

The hardware makes the following changes to the headers for subsequent packets that are derived as part of a TCP segmentation context:

Number of bytes left for transmission =  $PAYLEN - (N * MSS)$ . Where N is the number of frames that have been transmitted.

#### Tunnel Header

When tunnel offload is enabled (*Tunnel* bit set in the descriptor) the outer IPv4 header is updated as follows:

- IP Identification: increased from last value (wrap around based on 16-bit width)
- $IP\ Total\ Length = OUTERIPLEN + TUNNELLEN + IPLEN + L4LEN + MSS$
- Calculates the Outer IP Checksum

#### IPv4 Header

- IP Identification: increased from last value (wrap around)
- $IP\ Total\ Length = MSS + L4LEN + IPLEN$
- Calculate the IP Checksum

#### IPv6 Header

- $Payload\ Length = MSS + L4LEN + IPV6\_HDR\_extension^1$

---

1.  $IPV6\_HDR\_extension$  is calculated as  $IPLEN - 40$  bytes.

## TCP Header

- Sequence Number update: Add previous TCP payload size to the previous sequence number value. This is equivalent to adding the MSS to the previous sequence number.
- The flag values of the subsequent frames are set by logic AND function between the flag word in the pseudo header with the `DTXTCPFLGL.TCP_FLG_MID_SEG`. The default values of the `DTXTCPFLGL.TCP_FLG_MID_SEG` are set.
- Calculate the TCP checksum

## UDP Header

- Calculates the UDP checksum.

### 7.2.4.7.3 TCP/IP Header for the Last Frame

Hardware makes the following changes to the headers for the last frame of a TCP segmentation context:

Last frame payload bytes =  $\text{PAYLEN} - (\text{N} * \text{MSS})$ .

## Tunnel Header

When tunnel offload is enabled (*Tunnel* bit set in the descriptor) the outer IPv4 header is updated as follows:

- IP Identification: increased from last value (wrap around based on 16-bit width)
- IP Total Length =  $\text{OUTERIPLEN} + \text{TUNNELLEN} + \text{IPLLEN} + \text{L4LEN} + \text{last frame payload bytes}$ .
- Calculates the Outer IP Checksum

## IPv4 Header

- IP Total length = last frame payload bytes +  $\text{L4LEN} + \text{IPLLEN}$
- IP identification: increased from last value (wrap around based on 16-bit width)
- Calculate the IP checksum

## IPv6 Header

- Payload length = last frame payload bytes +  $\text{L4LEN} + \text{IPV6\_HDR\_extension}^1$

## TCP Header

- Sequence number update: Add previous TCP payload size to the previous sequence number value. This is equivalent to adding the MSS to the previous sequence number.
- The flag values of the last frames are set by logic AND function between the flag word in the pseudo header and the `DTXTCPFLGH.TCP_FLG_LST_SEG`. The default values of the `DTXTCPFLGH.TCP_FLG_LST_SEG` are set. The flags in a TSO that ends up as a single segment are taken from the in the pseudo header in the Tx data buffers as is.
- Calculate the TCP checksum

## UDP Header

- Calculates the UDP checksum.

---

1. `IPV6_HDR_extension` is calculated as  $\text{IPLLEN} - 40$  bytes.

## 7.2.5 Transmit Checksum Offloading in Non-Segmentation Mode

The previous section on TCP/UDP segmentation offload describes the IP/TCP/UDP checksum offloading mechanism used in conjunction with segmentation. The same underlying mechanism can also be applied as a stand-alone checksum offloading. The main difference in a single packet send is that only the checksum fields in the IP/TCP/UDP headers are calculated and updated by hardware.

Before taking advantage of the X550's enhanced checksum offload capability, a checksum context must be initialized. For a single packet send, *DCMD.TSE* should be set to zero (in the data descriptor). For additional details on contexts, refer to [Section 7.2.3.3](#).

Enabling checksum offload, software must also enable Ethernet CRC offload by the *HLREG0.TXCRCEN* since CRC must be inserted by hardware after the checksum has been calculated.

Each checksum operates independently. Insertion of the IP and TCP/UDP checksum for each packet are enabled through the transmit data descriptor *POPTS.TXSM* and *POPTS.IXSM* fields, respectively.

### 7.2.5.1 IP Checksum

Three fields in the transmit context descriptor set the context of the IP checksum offloading feature:

- *TUCMD.IPV4*
- *IPLLEN*
- *MACLEN*

*TUCMD.IPV4*=1 specifies that the packet type for this context is IPv4, and that the IP header checksum should be inserted. *TUCMD.IPV4*=0 indicates that the packet type is IPv6 (or some other protocol) and that the IP header checksum should not be inserted.

*MACLEN* specifies the byte offset from the start of the DMA'ed data to the first byte to be included in the checksum, the start of the IP header. The minimal allowed value for this field is 14. Note that the maximum value for this field is 127. This is adequate for typical applications.

**Note:** The *MACLEN*+*IPLLEN* value must be less than the total DMA length for a packet. If this is not the case, the results are unpredictable.

*IPLLEN* specifies the IP header length. Maximum allowed value for this field is 511 bytes.

*MACLEN*+*IPLLEN* specify where the IP checksum should stop. The sum of *MACLEN*+*IPLLEN* must be smaller equals to the first 638 (127+511) bytes of the packet and obviously must be smaller or equal to the total length of a given packet. If this is not the case, the result is unpredictable.

For IP tunnel packets (IPv4-IPv6), *IPLLEN* must be defined as the length of the two IP headers. Hardware is able to offload the L4 checksum calculation while software should provide the IPv4 checksum.

For NVGRE and VXLAN tunneled packet as defined by the *Tunnel* bit in the descriptor, Outer IPv4 checksum is controlled by *OUTERIPCS* bit and is determined by *MACLEN* and *OUTERIPLLEN* similar to the above description. Inner IPv4 checksum is controlled by *TUCMD.IPv4* and offset determination should be adjusted by hardware such that *MACLEN* should be replaced by (*MACLEN*+*OUTIPLLEN*+*TUNNELLEN*)

The 16-bit IPv4 header checksum is placed at the two bytes starting at *MACLEN*+10.

## 7.2.5.2 TCP and UDP Checksum

Three to five fields in the transmit context descriptor set the context of the TCP/UDP checksum offloading feature:

- *MACLEN*
- *OUTERIPLEN* (optional)
- *TUNNELLEN* (optional)
- *IPLLEN*
- *TUCMD.L4T*

*TUCMD.L4T*=01b specifies that the packet type is TCP, and that the 16-bit TCP header checksum should be inserted at byte offset  $MACLEN + IPLLEN + 16$ . *TUCMD.L4T*=00b indicates that the packet is UDP and that the 16-bit checksum should be inserted starting at byte offset  $MACLEN + IPLLEN + 6$ . If *Tunnel* bit is set, the checksum is inserted at  $MACLEN + OUTERIPLEN + TUNNELLEN + IPLLEN + 6$ .

$MACLEN + (OUTERIPLEN + TUNNELLEN) + IPLLEN$  specifies the byte offset from the start of the DMA'ed data to the first byte to be included in the checksum, the start of the UDP/TCP header. See *MACLEN* table in [Section 7.2.3.2.3](#) for its relevant values.

**Note:** The  $MACLEN + (OUTERIPLEN + TUNNELLEN) + IPLLEN + L4LEN$  value must be less than the total DMA length for a packet. If this is not the case, the results are unpredictable.

The TCP/UDP checksum always continues to the last byte of the DMA data.

**Note:** For non-TSO, software still needs to calculate a full checksum for the TCP/UDP pseudo-header. This checksum of the pseudo-header should be placed in the packet data buffer at the appropriate offset for the checksum calculation.

## 7.2.5.3 SCTP CRC Offloading

For SCTP packets, a CRC32 checksum offload is provided.

Three fields in the transmit context descriptor set the context of the STCP checksum offloading feature:

- *MACLEN*
- *IPLLEN*
- *TUCMD.L4T*

*TUCMD.L4T*=10b specifies that the packet type is SCTP, and that the 32-bit STCP CRC should be inserted at byte offset  $MACLEN + IPLLEN + 8$ .

$IPLLEN + MACLEN$  specifies the byte offset from the start of the DMA'ed data to the first byte to be included in the checksum, the start of the STCP header. The minimal allowed value for this sum is 26. See *MACLEN* table in [Section 7.2.3.2.3](#) for its relevant values.

The SCTP CRC calculation always continues to the last byte of the DMA data.

The SCTP total L3 payload size ( $PAYLEN - IPLLEN - MACLEN$ ) should be a multiple of four bytes (SCTP padding not supported).

**Note:** TSO is not available for SCTP packets.

**Note:** The CRC field of the SCTP header must be set by driver to zero prior to requesting a CRC calculation offload.

## 7.2.5.4 Checksum Supported per Packet Types

Table 7-45 lists which checksums are supported per packet type.

**Note:** TSO is not supported for packet types for which IP checksum and TCP/UDP checksum cannot be calculated.

**Table 7-45. Checksums Supported by Packet Type**

| Packet Type                                                                                                                                                                                                                                                               | Hardware IP Checksum Calculation                                                 | Hardware TCP/UDP/SCTP Checksum Calculation        |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------|---------------------------------------------------|
| IPv4 packets                                                                                                                                                                                                                                                              | Yes                                                                              | Yes                                               |
| IPv6 packets                                                                                                                                                                                                                                                              | No (n/a)                                                                         | Yes                                               |
| IPv6 packet with next header options: <ul style="list-style-type: none"><li>Hop-by-hop options</li><li>Destinations options</li><li>Routing (with len 0)</li><li>Routing (with len &gt;0)</li><li>Fragment</li><li>Home option</li><li>Security option (AH/ESP)</li></ul> | No (n/a)<br>No (n/a)<br>No (n/a)<br>No (n/a)<br>No (n/a)<br>No (n/a)<br>No (n/a) | Yes<br>Yes<br>Yes<br>No<br>No<br>No<br>Yes        |

1. The outer UDP header of VXLAN packets do not use a checksum.

## 7.2.6 Transmit Statistics

### 7.2.6.1 General Notes

- All Statistics registers are cleared on read. In addition, they stick at 0xFF...F when the maximum value is reached.
- Due to divergent paths between interrupt-generation and logging of relevant statistics counts, it might be possible to generate an interrupt to the system for a noteworthy event prior to the associated statistics count actually being increased. This is extremely unlikely due to expected delays associated with the system interrupt-collection and ISR delay, but might be an explanation for interrupt statistics values that do not quite make sense. Hardware guarantees that any event noteworthy of inclusion in a statistics count is reflected in the appropriate count within 1  $\mu$ s; a small time-delay prior to reading the statistics might be required to avoid a potential mismatch between and interrupt and its cause.
- If TSO is enabled, statistics are collected after segmentation.
- All byte (octet) counters composed of 2 registers can be fetched by two consecutive 32-bit accesses while reading the Low 32-bit register first or a single 64-bit access.

### 7.2.6.2 Transmit Statistics Hierarchy

Figure 7-22 describes the relations between the packet flow and the different statistic counters.

Figure 7-22. Transmit Flow Statistics

## 7.3 Interrupts

The X550 supports the following interrupt modes. Mapping of interrupts causes is different in each of these modes as described in this section.

- PCI legacy interrupts or MSI or MSI-X and only a single vector is allocated — Selected when `GPIE.MULTIPLE_MSIX` is set to 0b.
- MSI-X with multiple MSI-X vectors in non-IOV mode — Selected when `GPIE.MULTIPLE_MSIX` is set to 1b and `GPIE.VT_MODE` is set to 00b.
- MSI-X in IOV mode — Selected when `GPIE.MULTIPLE_MSIX` is set (as previously stated) and `GPIE.VT_MODE` DOES NOT equal 00b.

The following sections describe the interrupt registers and device functionality at all operation modes.

### 7.3.1 Interrupt Registers

#### 7.3.1.1 Physical Function (PF) Registers

The PF interrupt logic consists of the registers listed in the [Table 7-46](#) followed by their description:

**Table 7-46. PF Interrupt Registers**

| Acronym   | Complete Name                                                                                    |
|-----------|--------------------------------------------------------------------------------------------------|
| EICR      | Extended Interrupt Cause register                                                                |
| EICS      | Extended Interrupt Cause Set register (enables software to initiate interrupts)                  |
| EIMS      | Extended Interrupt Mask Set/Read register                                                        |
| EIMC      | Extended Interrupt Mask Clear register                                                           |
| EIAC      | Extended Interrupt Auto Clear register (following interrupt assertion)                           |
| EIAM      | Extended Interrupt Auto Mask register (auto set/clear of the EIMS)                               |
| EITR      | Extended Interrupt Throttling register (throttling)                                              |
| IVAR      | Interrupt Vector Allocation Registers (described in <a href="#">Section 7.3.4</a> )              |
| IVAR_MISC | Miscellaneous Interrupt Vector Allocation Register (described in <a href="#">Section 7.3.4</a> ) |

These registers are extended to 64 bits by an additional set of two registers. EICR has an additional two registers EICR(1)... EICR(2) and so on for the EICS, EIMS, EIMC, EIAM and EITR registers. The EIAC register is not extended to 64 bits as this extended interrupt causes are always auto cleared. Any reference to EICR... EIAM registers as well as any global interrupt settings in the GPIE register relates to their extended size of 64 bits.

The legacy EICR[15:0] mirror the content of EICR(1)[15:0]. In the same manner the lower 16 bits of EICS, EIMS, EIMC, EIAM mirror the lower 16 bits of EICS(1), EIMS(1), EIMC(1), EIAM(1). For more details on the use of these registers in the various interrupt modes (legacy, MSI, MSI-X) see [Section 7.3.4](#).

### 7.3.1.2 Virtual Function (VF) Registers

The VF interrupt logic has the same set of interrupt registers while each of them has three entries for three interrupt causes. The names and functionality of these registers are the same as those of the PF with a prefix of VT as follows: VFEICR, VFEICS, VFEIMS, VFEIMC, VFEIAM, VFEITR. The interrupt causes are always auto cleared. Although each VF can generate up to three interrupts, only the first two registers are capable of interrupt throttling and are associated to VFEITR registers (see [Section 7.3.4.3.2](#) for its proper usage). Each VF also has the mapping registers VFIVAR and VFIVAR\_MISC. Note that any global interrupt setting by the GPIE register affect both interrupt settings of the PF as well as the VFs.

### 7.3.1.3 Extended Interrupt Cause (EICR) Registers

This register records the interrupt causes to provide software information on the interrupt source. Each time an interrupt cause happens, the corresponding interrupt bit is set in the EICR registers. An interrupt is generated each time one of the bits in these registers is set, and the corresponding interrupt is enabled via the EIMS registers. The possible interrupt causes are as follows:

- Each *RTxQ* bit represents the following events: Tx or Rx descriptor write back; Rx queue full and Rx descriptor queue minimum threshold.
- Interrupts can be throttled by ITR as configured in the EITR register.
- Mapping the Tx and Rx queues to EICR is done by the IVAR registers as described in [Section 7.3.4](#). Each bit might represent an event on a single Tx or Rx queue or could represent multiple queues according to the IVAR setting. In the later case, software might not be able to distinguish between the interrupt causes other than checking all associated Tx and Rx queues.
- The *MULTIPLE\_MSIX* = 1b setting is useful when multiple MSI-X vectors are assigned to the device. When the *GPIE.MULTIPLE\_MSIX* bit is set, the *RTxQ* bits are associated with dedicated MSI-X vectors. Bit 0 is Tx/Rx interrupt associated with MSI-X vector 0 and bit 15 is Tx/Rx interrupt associated with MSI-X vector 15.

Writing a 1b to any bit in the register clears it. Writing a 0b to any bit has no effect. The EICR is also cleared on read if *GPIE.OCD* bit is cleared. When the *GPIE.OCD* bit is set, only bits 16...29 are cleared on read. The later setting is useful for MSI-X mode in which the Tx and Rx and possibly the timer interrupts do not share the same interrupt with the other causes. Bits in the register can be auto cleared depending on the EICR register setting (see [Section 7.3.1.6](#)).

### 7.3.1.4 Extended Interrupt Cause Set (EICS) Register

This register enables software to initiate a hardware interrupt. Setting any bit on the EICS sets its corresponding bit in the EICR register while bits written to 0b have no impact. It then causes an interrupt assertion if enabled by the EIMS register. Setting any bit generates throttled interrupt depending on the *GPIE.EIMEN* setting: When the *EIMEN* bit is set, setting the EICS register causes an LLI interrupt; When the *EIMEN* bit is cleared, setting the EICS register causes an interrupt after the corresponding interrupt throttling timer expires.

**Note:** The *EIMEN* bit can be set high only when working in auto-mask mode (*EIAM* bit of the associated interrupt is set).

### 7.3.1.4.1 EICS Affect on RSC Functionality

Setting EICS bits causes interrupt assertion (if enabled). EICS settings have the same impact on RSC functionality as nominal operation:

- In ITR mode ( $\text{GPIE.EIMEN} = 0\text{b}$ ), setting the EICS bits impact the RSC completion and interrupt assertion the same as any Rx packet. The functionality depends on the EICS setting schedule relative to the ITR intervals as described in [Section 7.3.2.1.1](#).
- In LLI mode ( $\text{GPIE.EIMEN} = 1\text{b}$ ), setting the EICS bits impact the RSC completion and interrupt assertion as follows:
  - Interrupt is asserted.
  - Concurrently, hardware triggers RSC completion in all Rx queues associated with the same interrupt.
  - Most likely these RSC(s) are completed to host memory after the interrupt is already asserted. In this case, it is guaranteed that an additional interrupt is asserted when the ITR expires.

### 7.3.1.5 Extended Interrupt Mask Set and Read (EIMS) Register, and Extended Interrupt Mask Clear (EIMC) Register

The Extended Interrupt Mask Set and Read (EIMS) register enables the interrupts in the EICR. When set to 1b, each bit in the EIMS register, enables its corresponding bit in the EICR. Software might enable each interrupt by setting bits in the EIMS register to 1b. Reading EIMS returns its value. Software might clear any bit in the EIMS register by setting its corresponding bit in the Extended Interrupt Mask Clear (EIMC) register. Reading the EIMC register does not return any meaningful data.

This independent mechanism of setting and clearing bits in the EIMS register saves the need for read modify write and also enables simple programming in multi-thread, multi-CPU core systems.

**Note:** The EICR register stores the interrupt events regardless of the state of the EIMS register.

### 7.3.1.6 Extended Interrupt Auto Clear Enable (EIAC) Register

Each bit in this register enables auto clearing of its corresponding bit in EICR following interrupt assertion. It is useful for Tx and Rx interrupt causes that have dedicated MSI-X vectors. When the Tx and Rx interrupt causes share an interrupt with the other or a timer interrupt, the relevant EIAC bits should not be set. Bits in the EICR register that are not enabled by auto clear, must be cleared by either writing a 1b to clear or a read to clear.

Note that there are no EIAC(1)...EIAC(2) registers. The hardware setting for interrupts 16...63 is always auto clear.

**Note:** Bits 29:16 should never be set to auto clear since they share the same MSI-X vector.

Writing to the EIAC register changes the setting of the entire register. In IOV mode, some of the bits in this register might affect VF functionality (VF-56...VF-63). It is recommended that software set the register in PF before VF's are enabled. Otherwise, a software semaphore might be required between the VF and the PF to avoid setting corruption.

### 7.3.1.7 Extended Interrupt Auto Mask Enable (EIAM) Register

Each bit in this register enables auto clearing and auto setting of its corresponding bit in the EIMS register as follows:

- Following a write of 1b to any bit in the EICS register (interrupt cause set), its corresponding bit in the EIMS register is auto set as well enabling its interrupt.
- A write to clear the EICR register clears its corresponding bits in the EIMS register masking further interrupts.
- A read to clear the EICR register, clears the *EIMS* bits (enabled by the EIAM) masking further interrupts. Note that if the *GPIE.OCD* bit is set, Tx and Rx interrupt causes are not cleared on read (bits 0:15 in the EICR). In this case, bits 0:15 in the EIMS are not cleared as well.
- In MSI-X mode the auto clear functionality can be driven by MSI-X vector assertion if *GPIE.EIAME* is set.

**Note:** Bits 29:16 should never be set to auto clear since they share the same MSI-X vector.

Writing to the EIAM register changes the setting of the entire register. In IOV mode, some of the bits in this register might affect VF functionality. It is recommended that software set the register in PF before VF's are enabled. Otherwise, a software semaphore might be required between the VF and the PF to avoid setting corruption.

If any of the *Auto Mask Enable* bits is set in the EIAM registers, the *GPIE.EIAME* bit must be set as well.

## 7.3.2 Interrupt Moderation

Interrupt rates can be tuned by the EITR register for reduced CPU utilization while minimizing CPU latency. In MSI or legacy interrupt modes, only EITR register 0 can be used. In MSI-X, non-IOV mode, the X550 includes 64 EITR registers 0...63 that are mapped to MSI-X vectors 0...63, respectively. In IOV mode, there are an additional 65 EITR registers that are mapped to the MSI-X vectors of the virtual functions. The mapping of MSI-X vectors to EITR registers are described in [Section 7.3.1.3](#).

### 7.3.2.1 Time-Based Interrupt Throttling — ITR

Time-based interrupt throttling is useful to limit the maximum interrupt rate regardless of network traffic conditions. The ITR logic is targeted for Rx/Tx interrupts only. It is assumed that the software device driver does not moderate the timer, other and mail box (IOV mode) interrupts. In non-IOV mode, all 64 interrupts can be associated with ITR logic. In IOV mode, the ITR logic is shared between the PF and VFs as shown in [Figure 7-23](#). The ITR mechanism is based on the following parameters:

- **ITR Interval** field in the EITR registers — The minimum inter-interrupt interval is specified in 2.048  $\mu$ s units (at 1 Gb/s or 10 Gb/s link). When the ITR Interval equals zero, interrupt throttling is disabled and any event causes an immediate interrupt. The field is composed of nine bits enabling a range of 2.048  $\mu$ s up to 1046.528  $\mu$ s. These ITR interval times correspond to interrupt rates in the range of 488 K INT/sec to 955 INT/sec. When operating at 100 Mb/s link, the ITR interval is specified in 20.48  $\mu$ s units.
  - Due to internal synchronization issues, the ITR interval can be shortened by up to 1  $\mu$ s at 10 Gb/s or 1 Gb/s link and up to 10  $\mu$ s at 100 Mb/s link when it is triggered by packet write back or interrupt enablement.

- **ITR Counter** partially exposed in the EITR registers — Down counter that is loaded by the ITR interval each time the associated interrupt is asserted.
  - The counter is decremented by one each 1.024  $\mu$ s (at 1 Gb/s or 10 Gb/s link) and stops decrementing at zero. At 100 Mb/s link, the speed of the counter is decremented by one each 10.24  $\mu$ s.
  - If an event happens before the counter is zero, it sets the EICR. The interrupt can be asserted only when the ITR time expires (counter is zero).
  - Else (no events during the entire ITR interval), the EICR register is not set and the interrupt is not asserted on ITR expiration. The next event sets the EICR bit and generates an immediate interrupt. See [Section 7.3.2.1.1](#) for interrupt assertion when RSC is enabled.
  - Once the interrupt is asserted, the ITR counter is loaded by the ITR interval and the entire cycle re-starts. The next interrupt can be generated only after the ITR counter expires once again.

### 7.3.2.1.1 ITR Affect on RSC Functionality

Interrupt assertion is one of the causes for RSC completion (see [Section 7.10.6](#)). When RSC is enabled on specific Rx queues, the associated ITR interval with these queues must be enabled and must be larger (in time units) than RSC delay. The ITR is divided to the two time intervals that are defined by the ITR interval and RSC delay. RSC completion is triggered after the first interval completes and the interrupt is asserted when the second interval completes.

The *RSC Delay* field is defined in the GPIE registers. *RSC Delay* can have one of the following eight values: 4  $\mu$ s, 8  $\mu$ s, 12  $\mu$ s... 32  $\mu$ s.

- The first ITR interval equals ITR interval minus RSC delay. The internal ITR counter starts at ITR interval value and counts down until it reaches the RSC delay value. Therefore, the ITR interval must be set to a larger value than the RSC delay.
- The second ITR interval equals RSC delay. The internal ITR counter continues to count down until it reaches zero.
- RSC completion can take some time (usually in the range of a few micro seconds). This time is composed by completing triggering latency and completing process latency. These delays should be considered when tuning the RSC delay. The clock frequency of the RSC completion logic depends on the link speed. As a result, the completion delay can as high as  $\sim 0.8 \mu$ s at 10 Gb/s link and  $\sim 8 \mu$ s at 1 Gb/s link. The RSC completion logic might take additional  $\sim 50$  ns at 10 Gb/s link and  $\sim 0.5 \mu$ s at 1 Gb/s link per RSC. In addition, there is the PCIe bus arbitration latency as well as system propagation latencies from the device up to host memory.
- Recommended RSC delay numbers are: 8  $\mu$ s at 10 Gb/s link and 28  $\mu$ s at 1 Gb/s link.
- RSC is not recommended when operating at 100 Mb/s link.

Following are cases of packet reception with respect to the ITR intervals:

- Packets are received and posted (including their status) to the Rx queue in the first ITR interval. In this case, RSC completion is triggered at the end of the first ITR interval and the interrupt is asserted at the second interval expiration.
- A packet (and its status) is received and posted to the Rx queue only after the first ITR interval has expired (either on the second interval or after the entire ITR interval has expired). In this case, RSC completion is triggered almost instantly (other than internal logic latencies). The interrupt is asserted at RSC delay time after the non-coalesced Rx status is queued to be posted to the host.
- Due to internal synchronization issues, the RSC delay can be shorten by up to 1  $\mu$ s when it is triggered by packet write back.

### 7.3.2.2 Immediate Interrupt

The X550 might initiate an immediate interrupt when the receive descriptor ring is almost empty (Rx descriptors below a specific threshold). The threshold is defined by `SRRCTL[n].RDMTS` per Rx queue. This mechanism can protect against memory resources being used up during reception of a long burst of short packets.

## 7.3.3 TCP Timer Interrupt

### 7.3.3.1 Introduction

To implement TCP timers, software needs to take action periodically (every 10 ms). Today, the driver must rely on software-based timers, whose granularity can change from platform to platform. This software timer generates a software NIC interrupt, which then enables the driver to perform timer functions, avoiding cache thrash and enabling parallelism. The timer interval is system-specific.

It would be more accurate and more efficient for this periodic timer to be implemented in hardware. The driver would program a timeout value (usual value of 10 ms), and each time the timer expires, hardware sets a specific bit in the EICR register. When an interrupt occurs (due to normal interrupt moderation schemes), software reads the EICR register and discovers that it needs to process timer events.

The timeout should be programmable by the driver, and the driver should be able to disable the timer interrupt if it is not needed.

### 7.3.3.2 Description

A stand-alone, down-counter is implemented. An interrupt is issued each time the value of the counter is zero.

Software is responsible for setting an initial value for the timer in the *Duration* field. Kick-starting is done by writing a 1b to the *KickStart* bit.

Following kick starting, an internal counter is set to the value defined by the *Duration* field. Then the counter is decreased by one each ms. When the counter reaches zero, an interrupt is issued. The counter re-starts counting from its initial value if the *Loop* field is set.

## 7.3.4 Mapping of Interrupt Causes

The following sections describe legacy, MSI and MSI-X interrupt modes.

### 7.3.4.1 Legacy and MSI Interrupt Modes

In legacy and MSI modes, an interrupt cause is reflected by setting one of the bits in the EICR register, where each bit reflects one or more causes. All interrupt causes are mapped to a single interrupt signal: either legacy INTA/B or MSI. This section describes the mapping of interrupt causes (that is a specific Rx or Tx queue event or any other event) to bits in the EICR.

The TCP timer and all other interrupt causes are mapped directly to EICR[30:16]. Note that the IVAR\_MISC register is not used in legacy and MSI modes.

Mapping the Tx and Rx queues to interrupt bits in the EICR register is programmed in the IVAR registers as shown in Figure 7-23. Each entry in the IVAR registers is composed of two fields that identify the associated bit in the EICR[15:0] register. Software might map multiple Tx and Rx queues to the same EICR bit.

- **INT\_Alloc** — Defines one of the bits (0...15) in the EICR register that reflects the interrupt status indication.
- **INT\_Alloc\_val** — Valid bit for the this interrupt cause.

**Figure 7-23. Cause Mapping in Legacy and MSI Modes**

Mapping between the Tx and Rx queue to the IVAR registers is hard-wired as shown in the Figure 7-24.

**Figure 7-24. Rx and Tx Queue Mapping to IVAR Registers**

### 7.3.4.2 MSI-X Mode in Non-IOV Mode

- MSI-X defines a separate optional extension to basic MSI functionality. Hardware indicates the number of requested MSI-X vectors in the table size in the MSI-X capability structure in the configuration space. The number of requested MSI-X vectors is loaded from NVM in the PCI\_CNF2.MSI\_X\_PF\_N field up to maximum of 64 MSI-X vectors. The operating system might allocate any number of MSI-X vectors to the device from a minimum of one up to the requested number of MSI-X vectors.
- Enables interrupts causes allocation to the assigned MSI-X vectors. Interrupt allocation is programmed by the IVAR registers and are described in this section.
- Each vector can use an independent address and data value as programmed directly by the operating system in the MSI-X vector table.
- Each MSI-X vector is associated to an EITR register with the same index (MSI-X 0 to EITR[0], MSI-X 1 to EITR[1],...).

For more information on MSI-X, refer to the PCI Local Bus Specification, Revision 3.0.

MSI-X vectors can be used for several purposes:

1. Dedicated MSI-X vectors per interrupt cause (avoids the need to read the interrupt cause register).
2. Load balancing by MSI-X vectors assignment to different CPUs.
3. Optimized interrupt moderation schemes per MSI-X vector using the EITR registers.

The MSI-X vectors are used for Tx and Rx interrupt causes as well as the other and timer interrupt causes. The remainder of this section describes the mapping of interrupt causes (such as a specific Rx or Tx queue event or any other event) to the interrupts registers and the MSI-X vectors.

The TCP timer and other events are reflected in EICR[30:16] the same as the legacy and MSI mode. It is then mapped to the MSI-X vectors by the IVAR\_MISC register as shown in [Figure 7-25](#). The IVAR\_MISC register includes two entries for the timer interrupt and an additional entry for all the other causes. The structure of each entry is as follows:

- **INT\_Alloc** — Defines the MSI-X vector (0...63) assigned to this interrupt cause.
- **INT\_Alloc\_val** — Valid bit for the this interrupt cause.

The Tx and Rx queues are associated to the IVAR0...IVAR63 the same as legacy and MSI mode shown in [Figure 7-24](#). The Tx and Rx queues are mapped by the IVAR registers to EICR(1),...EICR(2) registers and MSI-X vectors 0...63 illustrated in [Figure 7-25](#). The IVAR entries have the same structure as the IVAR\_MISC register previously shown. Each bit in EICR(1...2) registers is associated to MSI-X vector 0...63 as follows:

- EICR(i).bit\_num is associated to MSI-X vector ( $i \times 32 + \text{bit\_num}$ ).
- The legacy EICR[15:0] mirror the content of EICR(1)[15:0]. In the same manner the lower 16 bits of EICS, EIMS, EIMC, EIAM mirror the lower 16 bits of EICS(1), EIMS(1), EIMC(1), EIAM(1). The use of these registers depends on the number of assigned MSI-X interrupts as follows:
  - **16 Tx and Rx Interrupts** — When using up to 16 Tx and Rx interrupts, software might access the Tx and Rx interrupt bits in the legacy EICR, EICS,... registers.
  - **More than 16 Tx and Rx Interrupts** — When using more than 16 Tx and Rx interrupts, software must use EICS(1)...EICS(2), EIMS(1)...EIMS(2),... In the later case, software should avoid modifying the lower 16 bits in the EICS, EIMS... registers when it accesses the higher bits of these registers as follows:
    - EICR, EICS, EIMS and EIMC — When software programs the higher 16 bits of these registers, it should set their lower 16 bits to zero's keeping the EICR(1), EICS(1), EIMS(1) and EIMC(1) unaffected.
    - EIAM — When software programs the higher 16 bits, it should keep the lower 16 bits at their previous setting so the EIAM(1) is unaffected.
    - EIAC — When software programs the higher 16 bits, it should set the lower 16 bits to one's.
- **Single MSI-X vector** — If the operating system allocates only a single MSI-X vector, the driver might use the non-MSI-X mapping method (setting the GPIE.Multiple\_MSIX to 0b). In this case, the INT\_Alloc field in the IVAR registers might define one of the lower 16 bits in the EICR register while using MSI-X vector 0. The IVAR\_MISC should be programmed to MSI-X vector 0.

**Figure 7-25. Cause Mapping in MSI-X Mode (non-IOV)**

### 7.3.4.3 MSI-X Interrupts in IOV Mode

In IOV mode, interrupts must be implemented by MSI-X vectors. The X550 supports up to 64 virtual functions VF(0...63). Each VF can generate up to three MSI-X vectors. The number of requested MSI-X vectors per VF is loaded from NVM in the `PCI_CNF2.MSI_X_VF_N` field. It is reflected in the *Table Size* field in the PCIe MSI-X capability structure of the VF's. In addition, the PF requires its own interrupts. The number of requested MSI-X vectors is loaded from NVM in the `PCI_CNF2.MSI_X_PF_N` field up to maximum of 64 MSI-X vectors. It is reflected in the *Table Size* field in the PCIe MSI-X capability structure.

#### 7.3.4.3.1 MSI-X Vectors Used by Physical Function (PF)

PF is responsible for the timer and other interrupt causes that include the VM to PF mailbox cause (explained in the virtualization sections). These events are reflected in `EICR[30:16]` and MSI-X vectors are the same as the non-IOV mode (illustrated in Figure 7-23). When there are less than the maximum possible active VF's, some of the Tx and Rx queues can be associated with the PF. These queues can be used for the sake of additional VM's serviced by the hypervisor (the same as VMDq mode) or some Kernel applications handled by the hypervisor. Tx and Rx mapping to the IVAR registers is shown in Figure 7-24 and mapping to the EICR, `EICR(1)`,...`EICR(2)` registers as well as the MSI-X vectors is shown in Figure 7-25. See Section 7.3.4.3.3 for MSI-X vectors mapping of PF and VF's to the EITR registers.

**Note:** Software should not assign MSI-X vectors in the PF to Tx and Rx queues that are assigned to other VF's. In the case that VF's become active after the PF used the relevant Tx and Rx queues, it is the responsibility of the PF driver to clear all pending interrupts of the associated MSI-X vectors.

#### 7.3.4.3.2 MSI-X Vectors Used by Virtual Functions (VFs)

Each of the VFs in IOV mode is allocated separate IVAR(s) called VFIVAR registers, and a separate IVAR\_MISC called VFIVAR\_MISC register. The VFIVAR\_MISC maps the mailbox interrupt of the VF to its VFEICR and the MSI-X vector. The VFIVAR registers map the Tx and Rx interrupts of the VF to its VFEICR and the MSI-X vector. The mapping is similar to the mapping in the PF as shown in Figure 7-26 with the following comments:

- Each VF cannot have more than three MSI-X vectors. It has only three active bits in the VFEICR register while VFEICR.bit\_num is associated with MSI-X vector (bit\_num).
- The Tx and Rx interrupt can be mapped only to MSI-X 0 and MSI-X 1 (associated with VFEICR.0 and VFEICR.1).
- The mailbox interrupt can be mapped to any of the three MSI-X vectors. However, when all three of them are allocated by the operating system, software should map the mailbox to MSI-X 2 (associated with VFEICR.2). This rule should be kept since only VFEICR.0 and VFEICR.1 have ITR registers (VFEITR-0 and VFEITR-1).
- Association between the Tx and Rx queues and the VFIVAR registers is shown in the [Figure 7-26](#), [Figure 7-27](#) and [Figure 7-28](#) for IOV-64 (64 VF's), IOV-32 and IOV-16. The colored boxes in the figures show the mapping between VF Rx and Tx queues to VFIVAR registers while the dashed boxes show the physical IVAR registers and the associated physical Rx and Tx queues.

**Figure 7-26. VF Interrupt Cause Mapping (MSI-X, IOV)**

**Figure 7-27. VF Mapping of Rx and Tx Queue to VFIVAR in 64 VF's Mode**

**Figure 7-28. VF Mapping of Rx and Tx Queue to VFIVAR in 32 VF's Mode**

Figure 7-29. VF Mapping of Rx and Tx Queue to VFIVAR in 16 VF's Mode

### 7.3.4.3.3 MSI-X Vectors Mapping to EITR

EITR registers are aimed for Tx and Rx interrupt throttling. In IOV mode, the Tx and Rx queues might belong to either the PF or to the VF's. EITR(1...63) are multiplexed between the PF and the VF's as configured by the EITRSEL register. Figure 7-30 and Table 7-47 show the multiplexing logic and required software settings. For any active VF (starting from VF32 and above), software should program the matching bit in the EITRSEL to 1b. For any EITR that belongs to a VF, software should not map any interrupt causes in the PF to an MSI-X vector that is associated with the same EITR register.

Any RSCINT[n] register is associated with an MSI-X vector 'n'. As indicated above, the EITRSEL setting affects the MSI-X mapping. It also maps their associated RSCINT registers to either the PF or the VFs.

MSI-X 2 on each VF has no associated EITR register. It is useful for the mailbox interrupts that do not require interrupt moderation.

**Figure 7-30. PF/VF MSI-X Vectors Mapping to EITR**

**Table 7-47. PF/VF MSI-X Vectors Mapping Table to EITR Registers**

| VM Active                       | EITRSEL.N Setting             | MSI-X Routing to EITR                                   |
|---------------------------------|-------------------------------|---------------------------------------------------------|
| Non-IOV or VF(32...63) inactive | EITRSEL must be set to 0x0000 | MSI-X(1...63) -> EITR(1...63)                           |
| VF(32) active                   | EITRSEL[0] must be set to 1b  | VF(32) MSI-X(0) -> EITR(63)                             |
| VF(33) active                   | EITRSEL[1] must be set to 1b  | VF(33) MSI-X(1) -> EITR(62) VF(33) MSI-X(0) -> EITR(61) |
| VF(34) active                   | EITRSEL[2] must be set to 1b  | VF(34) MSI-X(1) -> EITR(60) VF(34) MSI-X(0) -> EITR(59) |
| ...                             | ...                           | ...                                                     |
| VF(62) active                   | EITRSEL[30] must be set to 1b | VF(62) MSI-X(1) -> EITR(4) VF(62) MSI-X(0) -> EITR(3)   |
| VF(63) active                   | EITRSEL[31] must be set to 1b | VF(63) MSI-X(1) -> EITR(2) VF(63) MSI-X(0) -> EITR(1)   |

## 7.4 802.1q VLAN Support

The X550 provides several specific mechanisms to support 802.1q VLANs:

- Optional adding (for transmits) and stripping (for receives) of IEEE 802.1q VLAN tags.
- Optional ability to filter packets belonging to certain 802.1q VLANs.

### 7.4.1 802.1q VLAN Packet Format

The following table compares an untagged 802.3 Ethernet packet with an 802.1q VLAN tagged packet:

| 802.3 Packet | #Octets | 802.1q VLAN Packet | #Octets |
|--------------|---------|--------------------|---------|
| DA           | 6       | DA                 | 6       |
| SA           | 6       | SA                 | 6       |
| Type/Length  | 2       | 802.1q Tag         | 4       |
| Data         | 46-1500 | Type/Length        | 2       |
| CRC          | 4       | Data               | 46-1500 |
|              |         | CRC*               | 4       |

**Note:** The CRC for the 802.1q tagged frame is re-computed, so that it covers the entire tagged frame including the 802.1q tag header. Also, maximum frame size for an 802.1q VLAN packet is 1522 octets as opposed to 1518 octets for a normal 802.3z Ethernet packet.

### 7.4.2 802.1q Tagged Frames

For 802.1q, the *Tag Header* field consists of four octets comprised of the Tag Protocol Identifier (TPID) and Tag Control Information (TCI); each taking two octets. The first 16 bits of the tag header makes up the TPID. It contains the protocol type that identifies the packet as a valid 802.1q tagged packet.

The two octets making up the TCI contain three fields as follows:

- User Priority (UP)
- Drop Eligible Indicator (DEI) — Should be set to 0b for transmits. For receives, the device has the capability to filter out packets that have this bit set. See the *DEIEN* and *DEI* bits in the *VLNCTRL*.
- VLAN Identifier (VID)

| Octet 1 |     | Octet 2 |
|---------|-----|---------|
| UP      | DEI | VID     |

## 7.4.3 Transmitting and Receiving 802.1q Packets

Since the 802.1q tag is only four bytes, adding and stripping of tags can be done completely in software. In other words, for transmits, software inserts the tag into packet data before it builds the transmit descriptor list, and for receives, software strips the 4-byte tag from the packet data before delivering the packet to upper layer software. However, because adding and stripping of tags in software adds overhead for the host, the X550 has additional capabilities to add and strip tags in hardware. See [Section 7.4.3.1](#) and [Section 7.4.3.2](#).

### 7.4.3.1 Adding 802.1q Tags on Transmits

The inner VLAN header can be added by software in one of the following methods:

- The header is included in the transmit data buffers.
- Software might instruct the X550 to insert an 802.1q VLAN tag on a per-packet basis. If the *VLE* bit in the transmit descriptor is set to 1b, the X550 inserts a VLAN tag into the packet that it transmits over the wire. The Tag Protocol Identifier — TPID (VLAN Ether Type) field of the 802.1q tag comes from the *DMATXCTL.VT*, and the Tag Control Information (TCI) of the 802.1q tag comes from the VLAN field of the legacy transmit descriptor or the *VLAN Tag* field of the advanced data transmit descriptor.
- In IOV mode, the priority tag, DEI and VLAN ID can be taken from the *PFVMVIR* (see details in [Section 7.8.4.2](#))

### 7.4.3.2 Stripping 802.1q Tags on Receives

Software might instruct the X550 to strip 802.1q VLAN tags from received packets. The policy whether to strip the VLAN tag is configurable per queue.

If the *RXDCTL.VME* bit for a given queue is set to 1b, and the incoming packet is an 802.1q VLAN packet (that is, its *Ethernet Type* field matched the *VLNCTRL.VET*), the X550 strips the 4-byte VLAN tag from the packet, and stores the TCI in the *VLAN Tag* field of the receive descriptor.

The X550 also sets the *VP* bit in the receive descriptor to indicate that the packet had a VLAN tag that was stripped. If the *RXDCTL.VME* bit is not set, the 802.1q packets can still be received if they pass the receive filter, but the VLAN tag is not stripped and the *VP* bit is not set. If *PFQDE.HIDE\_VLAN* is set, the VLAN tag is stripped as above, but the *VLAN Tag* field and the *STATUS.VP* bit in the Rx descriptor are cleared.

## 7.4.4 802.1q VLAN Packet Filtering

VLAN filtering is enabled by setting the *VLNCTRL.VFE* bit to 1b. If enabled, hardware compares the *Type* field of the incoming packet to a 16-bit field in the VLAN Ether Type (VET) register. If the *VLAN Type* field in the incoming packet matches the VET register, the packet is compared against the VLAN Filter Table Array for acceptance.

The VLAN filter register VTFA, is a vector array composed of 4096 bits. The VLAN ID (VID) is a 12-bit field in the VLAN tag that is used as an index pointer to this vector. If the VID in a received packet points to an active bit (set to 1b), the packet matches the VLAN filter. The 4096-bit vector is comprised of 128 x 32 bit registers. The upper 7 bits of the VID selects one of the 128 registers while the lower 5 bits map the bit within the selected register.

Two other bits in the VLNCTRL register, *DEIEN* and *DEI*, are also used in conjunction with 802.1q VLAN filtering operations. *DEIEN* enables the comparison of the value of the *DEI* bit in the 802.1q packet to the Receive Control register *DEI* bit as acceptance criteria for the packet.

**Note:** The *VFE* bit does not effect whether the VLAN tag is stripped. It only effects whether the VLAN packet passes the receive filter.

## 7.4.5 Double VLAN and Single VLAN Support

The X550 supports a mode where all received and sent packets have at least one VLAN tag in addition to the regular tagging that might optionally be added. In this document, when a packet carries two VLAN headers, the first header is referred to as an outer VLAN and the second header as an inner VLAN header (as listed in the table that follows). This mode is used for systems where the near end switch adds the outer VLAN header containing switching information. This mode is enabled by the following configuration:

- This mode is activated by setting the *DMATXCTL.GDV* and the *EXTENDED\_VLAN* bit in the *CTRL\_EXT* register.
- The Ethertype of the VLAN tag used for the additional VLAN is defined in the *VET\_EXT* field in the *EXVET* and *EXVET\_T* registers.

### 7.4.5.1 Cross Functionality with Manageability

The X550 does not provide any stripping or adding VLAN header(s) to manageability packets. Therefore, packets that are directed to/from the manageability controller should include the VLAN headers as part of the Rx/Tx data. The manageability controller should know if the X550 is set to double VLAN mode as well as the VLAN Ethertype(s).

**Table 7-48. Double VLAN Packet Format**

| MAC Address | Outer VLAN | Inner VLAN | L2 Payload | Ethernet CRC |
|-------------|------------|------------|------------|--------------|
|-------------|------------|------------|------------|--------------|

### 7.4.5.2 Transmit Functionality

#### 7.4.5.2.1 Transmit Functionality on the Outer VLAN Header

- A packet with a single VLAN header is assumed to have only the outer VLAN.
- The outer VLAN header must be added by software as part of the Tx data buffers.
- Hardware does not relate to the outer VLAN header other than the capability of skipping it for parsing inner fields.
- Hardware expects that any transmitted packet (see the disclaimer that follows) has at least the outer VLAN added by software. For any offload that hardware might provide in the transmit data path, hardware assumes that the outer VLAN is present. For those packets that an outer VLAN is not present, any offload that relates to inner fields to the Ethertype might not be provided.

### 7.4.5.2.2 Transmit Functionality on the Inner VLAN Header

- Inner VLAN insertion is handled as described in [Section 7.4.3.1](#).
- Hardware identifies and skips the VLAN header for parsing inner fields.
- DCB — The traffic class is dictated by the Tx queue.
- Pool Filtering — Destination pool(s) and anti-spoofing functionality is based on the Ethernet MAC Address and inner VLAN (if present) as described in [Section 7.8.3.4](#) and [Section 7.8.4.2](#).

### 7.4.5.3 Receive Handling of Packets with VLAN Header(s)

A received frame is analyzed for the existence of the outer and inner VLAN headers. The procedure is as follows:

```

Check the Ethertype against the outer VLAN ID. If match then
{
    Check the next Ethertype against the inner VLAN ID. If match
    {
        This is the double VLAN case. Process both outer and inner VLANs as described below
    }
    Else
    {
        Only an outer VLAN exists. Process the outer as described below. Assume no inner VLAN
    }
}
Else
{
    Check the Ethertype against the inner VLAN ID. If match
    {
        This is the case of an inner VLAN only. Handle the frame as an unknown frame - device
        does not provide any offloads
    }
    Else
    {
        This is the case of no VLAN. Process the frame (ignore outer and inner VLAN processing)
    }
}

```

#### 7.4.5.3.1 Receive Functionality on the Outer VLAN Header

- Hardware checks the Ethertype of the outer VLAN header against the programmed value in the EXVET register. VLAN header presence is indicated in the STATUS.VEXT bit in the Rx descriptor.
- The outer VLAN header is posted as is to the receive data buffers.

#### 7.4.5.3.2 Receive Functionality on the Inner VLAN Header

- Hardware checks the Ethertype of the inner VLAN header against the programmed value in the VLNCTRL.VET. VLAN header presence is indicated in the STATUS.VP bit in the Rx descriptor.
- L2 packet filtering is based on the VLAN ID in the inner VLAN header.
- Pool Filtering — Destination pool(s) are defined by the Ethernet MAC Address and inner VLAN (if presence) as described in [Section 7.8.3.3](#).
- Inner VLAN tag striping is handled as described in [Section 7.4.3.2](#).

## 7.4.5.4 Packets with No VLAN Headers in Double VLAN Mode

There are some cases when packets might not carry any VLAN headers, even when extended VLAN is enabled. A few examples for packets that might not carry any VLAN header are: flow control and priority flow control, LACP, LLDP, GMRP, and optional 802.1x packets. When it is expected to transmit untagged packets by software in Double VLAN Mode the software must not enable VLAN anti-spoofing and VLAN validation nor transmit to receive switching.

### 7.4.5.4.1 Transmit Functionality

DCB — The TC in the Tx data path is directed by the Tx queue of the transmitted packet.

Transmit offload functionality — Software should not enable any offload functions.

### 7.4.5.4.2 Receive Functionality

Receive offload functionality — pool and queue are selected by the Ethernet MAC Address or ETQF/ETQS registers. Filtering to host and manageability remains functional.

## 7.4.5.5 Packets with Two VLAN Headers Not in Double VLAN Mode

When the *EXTENDED\_VLAN* bit in the CTRL\_EXT register and *DMATXCTL.GDV* are not set, hardware expects that Rx and Tx packets might not carry a VLAN header or a single VLAN header. Hardware does not relate to the programming of the *VET\_EXT* field in the EXVET register. Tx and Rx handling of packets with double VLAN headers is unexpected.

## 7.4.6 E-tag and VLAN

In some systems an additional external tag (E-tag) can be present before the VLAN. This section describes the support for VLANs in presence of external tags. This mode is used for systems where the device adds a tag to identify a subsystem (usually a VM) and the near end switch adds a tag indicating the destination subsystem. External tags may be present on part of the packets and missing in others.

### 7.4.6.1 Transmit Functionality

#### 7.4.6.1.1 Transmit Functionality on the External Tag

The X550 supports insertion of an external tag from a per pool register (PFVMTIR - [Section 8.2.2.22.30](#)) and a VLAN tag from a per pool register (PFVMVIR - [Section 8.2.2.22.14](#)) or from the descriptor as indicated by the *VLE* bit. The following options are supported:

| VLAN source/External Tag Source | Hardware Register - PFVMTIR/PFVMVIR | Embedded in Packet |
|---------------------------------|-------------------------------------|--------------------|
| Hardware register - PFVMVIR     | Supported                           | Not supported      |
| Descriptor                      | Supported                           | Not supported      |
| Embedded in Packet              | Supported                           | Supported          |

After the tags are inserted in the packet, the X550 uses the VLAN tag and the Ethertype as part of the forwarding decision as described in [Section 7.8.3.4](#). In a packet with at most one external tag and one VLAN, the VLAN and Ethertype are identified correctly.

## 7.4.6.2 Receive Handling of Packets with External Tags

External tags can be extracted from the packet according to the `PFQDE.STRIP_TAG` field ([Section 8.2.2.22.4](#)). Inner tag extraction is handled as described above ([Section 7.4.3.2](#)).

### 7.4.6.2.1 Packet Priority in Presence of External Tags

The user priority used to define the traffic class of a packet is always taken from the inner VLAN

## 7.4.6.3 Cross Functionality with Manageability

The X550 does not provide any stripping or adding VLAN header(s) to manageability packets. Therefore, packets that are directed to/from the manageability controller should include the L2 headers as part of the Rx/Tx data. The manageability controller should know if it is expected to add/receive an external tag as part of the packet.

## 7.4.6.4 Packet User Priority (802.1P) Bits Handling

The user priority bits may be used by the device for multiple purposes:

1. Defining the traffic class to which the traffic is associated ([Section 7.6.3.1](#)).
2. Defining which packets get a Timestamp in Buffer ([Section 7.1.6.2](#)).
3. Defining if a packet matches and Ethertype filter ([Section 7.1.3.3](#)).

For all these purposes, the *UP* bits are taken from the outermost tag with *UP* bits (E-tag or VLAN), unless the `VLNCTRL.UP_FIRST_TAG_EN` bit is cleared, in which case, it is always taken from the inner VLAN.

The table below summarize the tag from which the user priority is extracted from the packets.

**Table 7-49. UP Extraction Rules**

| Packet Type                                               | <code>VLNCTRL.UP_FIRST_TAG_EN = 1b</code>          | <code>VLNCTRL.UP_FIRST_TAG_EN = 0b</code>                                                                                  |
|-----------------------------------------------------------|----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| Un-tagged Packet                                          | User priority = 0                                  | User priority = 0                                                                                                          |
| Packet with a single VLAN                                 | The user priority field from the VLAN header.      | <b>Single VLAN mode:</b><br>The user priority field from the VLAN header.<br><b>Double VLAN mode:</b><br>User priority = 0 |
| Packet with a VLAN and an outer tag (outer VLAN or E-tag) | The user priority field from the outer VLAN header | The user priority field from the inner VLAN header.                                                                        |
| Packet with E-tag only                                    | The user priority field from the E-tag             | User priority = 0                                                                                                          |

## 7.5 TLP Processing Hints (TPH)

The X550 supports the TPH capability defined in the PCI Express specification. It does not support Extended TPH requests.

On the PCIe link existence of a TLP Process Hint (TPH) is indicated by setting the *TH* bit in the TLP header. Using the PCIe TLP Steering Tag (ST) and Processing Hints (PH) fields, the X550 can provide hints to the root complex about the destination (socket ID) and about data access patterns (locality in Cache), when executing DMA memory writes or read operations. Supply of TLP Processing Hints facilitates optimized processing of transactions that target Memory Space.

To enable TPH usage:

1. For a given function, the *TPH Requester Enable* bit in the PCIe configuration TPH Requester Control Register should be set.
2. Appropriate *TPH Enable* bits in TPH\_RXCTRL or TPH\_TXCTRL registers should be set.
3. Processing hints should be programmed in the TPH\_CTRL.DESC\_PH and TPH\_CTRL.DATA\_PH Processing hints (PH) fields.
4. Steering information should be programmed in the CPUID fields in the TPH\_RXCTRL and TPH\_TXCTRL registers.

The Processing hints (PH) and Steering Tags (ST) are set according to the characteristics of the traffic as described in [Table 7-50](#).

**Note:** To enable TPH usage, all the memory reads are done without setting any of the byte enable bits.

**Note:** Per queue, the TPH features are exclusive. Software can enable the TPH feature for a given queue.

### 7.5.1 Steering Tag and Processing Hint Programming

[Table 7-50](#) describes how the Steering tag (socket ID) and Processing hints are generated and how TPH operation is enabled for different types of DMA traffic.

**Table 7-50. Steering Tag and Processing Hint Programming**

| Traffic type                                      | ST Programming                | PH value                      | Enable                                                                    |
|---------------------------------------------------|-------------------------------|-------------------------------|---------------------------------------------------------------------------|
| Transmit descriptor write back or head write back | TPH_TXCTRL.CPUID <sup>1</sup> | TPH_CTRL.DESC_PH <sup>2</sup> | <i>Tx Descriptor Writeback TPH EN</i> field in TPH_TXCTRL.                |
| Receive data buffers write                        | TPH_RXCTRL.CPUID <sup>1</sup> | TPH_CTRL.DATA_PH <sup>3</sup> | <i>Rx Header TPH EN</i> or <i>Rx Payload TPH EN</i> fields in TPH_RXCTRL. |
| Receive descriptor writeback                      | TPH_RXCTRL.CPUID <sup>1</sup> | TPH_CTRL.DESC_PH <sup>2</sup> | <i>Rx Descriptor Writeback TPH EN</i> field in TPH_RXCTRL.                |
| Transmit descriptor fetch                         | TPH_TXCTRL.CPUID <sup>4</sup> | TPH_CTRL.DESC_PH <sup>2</sup> | <i>Tx Descriptor Fetch TPH EN</i> field in TPH_TXCTRL.                    |
| Receive descriptor fetch                          | TPH_RXCTRL.CPUID <sup>2</sup> | TPH_CTRL.DESC_PH <sup>2</sup> | <i>Rx Descriptor fetch TPH EN</i> field in TPH_RXCTRL.                    |
| Transmit packet read                              | TPH_TXCTRL.CPUID <sup>2</sup> | TPH_CTRL.DATA_PH <sup>3</sup> | <i>Tx Packet TPH EN</i> field in TPH_TXCTRL.                              |

1. The driver should always set bits [7:3] to zero and place Socket ID in bits [2:0].
2. Default is 00b (Bidirectional data structure).
3. Default is 10b (Target).
4. The hints are always zero.

## 7.6 Data Center Bridging (DCB)

See [Section 4.6.11](#) for the DCB configuration sequence.

### 7.6.1 Overview

DCB is a set of features that improve the capability of Ethernet to handle multiple traffic types (such as LAN, storage, IPC) by answering the various needs of those types. DCB enables multiple traffic types that have different requirements of packet delivery, bandwidth allocation and delay. Each traffic type can have one or several user priorities, or Traffic Classes (TCs). For example, IPC might have a high priority class for synchronization messages between servers and lower priority traffic class for bulk traffic exchange between servers. Most of the DCB functions impact the transmit traffic generated from the end node to the network (traffic generation). The receive data path needs be compliant with the requirements of DCB and provide the required functions as a traffic termination point.

DCB system requirements include:

- **Bandwidth grouping** — For effective multiplexing that simulates a separate link for the separate types of traffic, DCB requires that traffic types be recognized as groups in the bandwidth and priority handling by nodes in the network. Traffic types are associated to Bandwidth Groups (BWGs). The system needs to be able to allocate bandwidth to the BWGs in a way that emulates that group being on its own separate link.
- **Bandwidth fairness** — DCB multiplexing functions (transmit) and de-multiplexing functions (receive) need to guarantee minimum allocation of bandwidth to traffic types and traffic classes. Fairness between groups comes first, then fairness between TCs. If system resources (such as PCIe bandwidth) limit total throughput, then the available bandwidth should be distributed among consumers proportionally to their allocations.
- **Latency of operation** — DCB multiplexing and de-multiplexing functions need to allow minimum latency for some TCs. Arbitration mechanisms, packet buffers, descriptor queues and flow control algorithm need to be defined and designed to allow this. The best example is the control/sync traffic in IPC. The expectation for end-to-end IPC control is measured in the low 10's of  $\mu$ s for the X550 and is expected to drop to a single digit  $\mu$ s later. Some elements in multimedia traffic also bear similar requirements. Although some of the end-to-end delays can be quite long, the individual contribution of the arbitration in each node must be kept to a minimal. End-to-end budgets do not comprehend large delays within transmission nodes.
- **No-drop behavior and network congestion management** — The end node must be able to guarantee no-drop behavior for some TCs or some packets within TCs. As a termination point in receive, it is the end node's responsibility to properly control traffic coming from the network to achieve this end. For traffic generation in transmit, the end station must be able to positively respond to flow control from the network as the must have tool to prevent packet drop. It also needs to participate in network congestion management.
- **Compatibility with existing systems** — The DCB implementation needs to be usable by IT using known configurations and parameters, unless new ones are made expressly available. For example, DCB implementation cannot assume new knowledge regarding bandwidth allocation of traffic types that do not have known bandwidth requirements.

The layer 2 features of DCB implemented in the X550 are:

- **Multi-class priority arbitration and scheduling** — The X550 implements an arbitration mechanism on its transmit data path. The arbitration mechanism allocates bandwidth between TC in BWGs and between Virtual Machines (VMs) or Virtual Functions (VFs) in a virtualization environment. The BWGs can be used to control bandwidth and priority allocated to traffic types. Typically BWGs should be used to represent traffic types. TC arbitration allows control of bandwidth and priority control within BWGs as well as within the entire link bandwidth. The arbitration is designed to respect the bandwidth allocations to BWGs. The priority allocation allows minimization of delay for specific TCs. In the X550, TCs and user priorities are processed on a packet-by-packet basis based on the 802.1p identifier in the 802.1Q-tag.
- **Class-based flow control (PFC — Priority Flow Control)** — Class-based flow control functionality is similar to the IEEE802.3X link flow control. It is applied separately to the different TCs.
  - Transmit response to class-based flow control from the ingress switch it is connected to.
  - Receive class-based flow control commands to the switch in response to packet buffers filling status.
- **DMA queuing per traffic type** — Implementation of the DCB transmit, minimization of software processing and delays require implementation of separate DMA queues for the different traffic types. The X550 implements 128 descriptor queue in transmit and 128 descriptor queues in receive.
- **Multiple Buffers** — The X550 implements separate transmit and receive packet buffers per TC.
- **Rate-limiter per Tx queue** — Limiting the transmit data rate for each Tx queue.

#### Latency requirements:

Quantitative latency requirements are defined for a single 64-byte packet at the highest priority traffic class. Latency is defined separately for transmit and receive:

- **Transmit latency** — Measured from a tail update until the packet is transmitted on the wire. It is assumed that a single packet is submitted for this TC and its latency is then measured in the presence of traffic belonging to other TCs.
- **Receive latency** — Measured from packet reception from the wire and until the descriptor is updated on PCIe.

Figure 7-31 shows the latency requirements as previously defined.

**Figure 7-31. Latency Requirements**

**Note:** In DCB mode, it is assumed all traffic is tagged (contains a VLAN header) — except for Layer2 frames with special Ethernet MAC Addresses that goes un-tagged. GMRP frames (special Ethernet MAC Addresses starting with 0x0180C20000) must, however, go tagged. Un-tagged packets must be delivered to the host and are assumed to belong to User Priority 0.

## 7.6.2 Transmit-Side Capabilities

When configured for DCB mode or when using the Tx rate-limiting functionality, the X550 software driver should only use advanced transmit descriptors. Refer to [Section 7.2.3.2.3](#).

### 7.6.2.1 Transmit Rate Scheduler (RS)

#### 7.6.2.1.1 Basic Rate Control Operation

Rate control is defined in terms of maximum payload rate, and not in terms of maximum packet rate. This means that each time a rate controlled packet is sent, the next time a new packet can be sent out of the same rate controlled queue is relative to the packet size of the last packet sent. The minimum spacing in time between two starts of packets sent from the same rate controlled queue is recalculated in hardware on every packet again, by using the following formula:

$$\text{MIFS} = \text{PL} \times \text{RF}$$

Where:

- Packet Length (PL), is the Layer2 length (such as without preamble and IPG) in bytes of the previous packet sent out of that rate controller. It is an integer ranging from 64 to 9 K (at least 14-bits).
- RF = 10 Gb/s / target rate (rate factor) is the ratio between the nominal link rate and the target maximum rate to achieve for that rate-controlled queue. It is dynamically updated by software via the RTTQCNRC register or periodically according to the self-recovery algorithm run in software. It is a decimal number ranging from 1 to 1,000 (10 Mb/s minimum target rate). For example, at least 10 bits before the hexadecimal point and 14 bits after as required for the maximum packet length by

which it is multiplied. For links at 1 Gb/s, the rate factor must be configured relatively to the link speed, replacing 10 Gb/s by 1 Gb/s in the above formula.

- Minimum Inter Frame Space (MIFS) is the minimum delay in bytes units, between the starting of two Ethernet frames issued from the same rate-controlled queue. It is an integer ranging from 76 to 9,216,012 (at least 24 bits). In spite of the 8-byte resolution provided at the internal data path, the byte-level resolution is required here to maintain an acceptable rate resolution (at 1% level) for the small packets case and high rates.

**Note:** It might be that a pipeline implementation causes the MIFS calculated on a transmitted packet to be enforced only on the subsequent transmitted packet.

**Time Stamps** — A rate-scheduling table contains the accumulated interval MIFS, for each rate-controlled descriptor queue separately, and is stored as an absolute Time Stamp (TS) relative to an internal free running timer. The TS value points to the time in the future at which a next data read request can be sent for that queue. Whenever updating a Timestamp:

$$\text{TimeStamp}(\text{new}) = \text{TimeStamp}(\text{old}) + \text{MIFS}$$

When a descriptor queue starts to be rate controlled, the first interval MIFS value is equal to 0 (TS equal to the current timer value) — without taking into account the last packet sent prior to rate control. When the TS value stored becomes equal to or smaller than the current free running timer value, it means that the switch is on and that the queue starts accumulating compensation times from the past (referred as a negative TS). When the TS value stored is strictly greater than the current free running timer value, it means that the switch is off (referred as a positive TS).

$(\text{CurrentTime}) < \text{TimeStamp} \quad \text{<-->}$  switch is off

$(\text{CurrentTime}) \geq \text{TimeStamp} \quad \text{<-->}$  switch is on

**MMW** — The ability to accumulate negative compensation times that saturates to a Max Memory Window (MMW) time backward. MMW size is configured per TC via the *MMW\_SIZE* field of the RTTQCNRM register, and is expressed in 1 KB units of payload, ranging from 0 up to 2 KB units (at least 11 bits). The *MMW\_SIZE* configured in KB units of payload has to be converted in time interval *MMW\_TIME* expressed in KB, before a new time stamp is checked for saturation. It is computed for each queue according to its associated Rate Factor (RF) using the following formula:

$$\text{MMW\_TIME} = \text{MMW\_SIZE} \times \text{RF}$$

**Note:** *MMW\_TIME* is rounded by default to a 1 KB precision level and must be at least 31 bits long. Hence, the time stamp byte-level values stored must be at least 32 bits long for properly handling the wrap-around case. 29 bits are required for the internal free running timer clocked once every 8 bytes.

Whenever updating a time stamp verify:

$$\text{TimeStamp}(\text{old}) + \text{MIFS} \geq (\text{CurrentTime}) - \text{MMW\_TIME}$$

and then the time stamp is updated according to the non-saturated formula:

$$\text{TimeStamp}(\text{new}) = \text{TimeStamp}(\text{old}) + \text{MIFS}$$

Otherwise, enforced saturation by assigning:

$$\text{TimeStamp}(\text{new}) = (\text{CurrentTime}) - \text{MMW\_TIME} + \text{MIFS}$$

**Note:** Non-null MMW introduces some flexibility in the way controlled rates are enforced. It is required to avoid overall throughput losses and unfairness caused by rate-controlled packets over-delayed, consequently to packets inserted in between. Between two rate-limited packets spaced by at least the MIFS interval, non-rate-limited packets, or rate-limited packets from other rate-controlled queues, might be inserted. If a rate controlled packet has been delayed by more time than it was required for rate control (because of arbitration between VMs or TCs), the next MIFS accumulates from the last time the queue was switched on by the QCN

rate scheduling table — and not from the current time. Refer to [Figure 7-32](#) for visualizing the effect of MMW.

MMW\_SIZE set to 0b must be supported as well.

**Figure 7-32. Minimum Inter-Frame Spacing for Rate-Controlled Frames (in Orange)**

## 7.6.2.2 User Priority to Traffic Class Mapping

DCB-enabled software is responsible for classifying any Tx packet into one of the eight 802.1p user priorities, and to assure it is tagged accordingly by either software or hardware. The driver dispatches classified Tx traffic into the Tx queues attached to the proper TC, according to a UP-to-TC Tx mapping policy decided by the IT manager.

**Caution:** When translating XON/XOFF priority flow control commands defined per UP into commands to the Tx packet buffers, the X550 is required to use the same UP-to-TC Tx mapping table that software is using. The RTTUP2TC register must be configured by software accordingly. Refer to [Section 3.7.4.1.3](#) for details on priority flow control.

### 7.6.2.3 VM-Weighted Round-Robin Arbiters

The X550 implements VM-weighted arbiter(s) for virtualized environments and according to the following case:

- If DCB is enabled, there is one such arbiter per TC, arbitrating between the descriptor queues attached to the TC (one queue per VF). Bandwidth allocation to VMs is enforced at the descriptor plane, per each TC separately. The VM arbiter instantiated for each TC is aimed to elect the next queue for which a data read request is sent in case the TC is elected for transmission by the next level arbiter. For example, the TC weighted strict priority descriptor plane arbiter.
- If DCB is disabled, there is one single VM weighted arbiter, arbitrating between pools of descriptor queues, where a pool is formed by the queues attached to the same VF. Bandwidth allocation to VMs is enforced at the descriptor plane, between the pools, where queues within a pool are served on a frame-by-frame round-robin manner.

Refer to the different arbitration schemes where virtualization is enabled, as described in [Section 7.8](#).

**Note:** In this section, VM is considered a generic term used to refer to the arbitrated entity, whether it is a Tx descriptor queue within the TC or whether it is a pool of Tx descriptor queues. In the later case, pool parameters are allocated only to the lowest indexed queue within the pool, taken as the representation of the entire pool.

#### 7.6.2.3.1 Definition and Description of Parameters

**Credits:** Credits regulate the bandwidth allocated to VMs. As part of the Weighted Round Robin (WRR) algorithm, each VM has pre-allocated credits. They are decremented upon each transmission and replenished cyclically. The ratio between the credits of the VMs represents the relative bandwidth percentage allocated to each VM (within the TC for the DCB enabled case). The X550 effectively maintains one table that represents these ratios. Note that credits can get negative values down to the maximum sized frame allowed on the TC/pool.

**Note:** The absolute value of the credits has no direct bearing on the allocation of bandwidth. The ratio between the credits does. However, since credits can accumulate only up to twice the credit refills, the refills should be allocated as low as possible but must be set greater than the maximum sized frame allowed on the TC or on the pool.

**WRR:** The algorithm implemented in the X550 for VM arbitration.

[Table 7-51](#) (T1) defines the VMs and their bandwidth allocation. The following elements are defined in this table:

**Table 7-51. Bandwidth Allocation to VMs**

| T1: VM Bandwidth Allocation                                                                                                                                                                                             |              |                |                |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|----------------|----------------|
| VM <sub>N</sub>                                                                                                                                                                                                         | VM Refill    | VM Max Credits | VM Min Credits |
| 0                                                                                                                                                                                                                       | MSS:1,024 KB | 2xMSS:2,048 KB | -MSS           |
| 1                                                                                                                                                                                                                       | MSS:1,024 KB | 2xMSS:2,048 KB | -MSS           |
| 2                                                                                                                                                                                                                       | MSS:1,024 KB | 2xMSS:2,048 KB | -MSS           |
| 3                                                                                                                                                                                                                       | MSS:1,024 KB | 2xMSS:2,048 KB | -MSS           |
| ...                                                                                                                                                                                                                     |              |                |                |
| 15                                                                                                                                                                                                                      | MSS:1,024 KB | 2xMSS:2,048 KB | -MSS           |
| † Due to a pipelined implementation, the VM credits range is enlarged by one MSS, beyond negative limits.<br>†† All values are implemented with 64-byte granularity (a value of one corresponds to 64 bytes of credit). |              |                |                |

**VM:** Configuration — The unique Tx descriptor queue attached to a VF within a TC, or the pool of Tx descriptor queues attached to the same VF.

**VM Credit Refill:** Configuration — The X550's WRR algorithm implement credit refill as the technique for percentage allocation to VMs. The credits refill are added to each VM credit count on each completion of the full round of the algorithm (after all the VMs had their chance to send what they had in store or at least one frame).

The X550's driver needs to calculate the VM credit refill to match the percent allocated through management (such as in the MIB). Since the WRR arbitration is self timed, the ratio between the credits refill is the only defining parameter for the VMs. However, the refills must be greater or equal to the maximum sized frame allowed on the TC or on the pool to guaranty transmission of at least one frame on each recycling round. The X550 allows a value of 1.5 KB to 1,024 KB for a dynamic range of x1000.

**VM Maximum Accumulated Credits:** Deducted from Refill Configuration — To prevent the use of stale credits, the number of credits each VM can accumulate upon refill is limited. The credits for each VM can only reach twice their refill. The maximum range for the credits is thus -9.5 KB to 2,048 KB, assuming negative credits can accumulate up to a maximum sized frame (9.5 KB if jumbo frames are allowed), and where positive credits can accumulate up to twice the maximum credit refill.

**VM Credits:** Run time parameter — VM credits is a running counter for each VM. It holds the number of available credits in 64-byte units. The algorithm runs sequentially between the VMs and enables transmission for those VMs that have enough pending credits (their credit number is greater than zero).

**Table 7-52. Registers Allocation for Tx VM Arbiters**

| Attribute            | Tx VM Arbiter |
|----------------------|---------------|
| VM Control registers | RTTDT1C       |
| VMC Status registers | RTTDT1S       |
| VM credit refill     | CRQ           |
| VM credits           | CCC           |

### 7.6.2.3.2 WRR Arbiter Algorithm

**Note:** This feature should be combined with configuring at least twice the sum of T1[VM]. Refills over a TC to its corresponding T2.[TC]MaxCredits. See [Section 4.6.11.4.1](#) for details.

**Round Robin** — The round-robin aspect of the VM WRR arbiter resides in the fact that once a VM has been granted for a data read request, the next VMs are checked in a cyclic round-robin order, even if the granted VM still has credits for another data read request.

Figure 7-33. Tx VM WRR Arbiters Operation

## 7.6.2.4 Tx TC Weighted Strict Priority Arbiters

In DCB, multiple traffic types are essentially multiplexed over the Ethernet 10 Gb/s network. There is a need to allow different behavior to different traffic flows as they pass-through multiple Ethernet switches and links. For example, for LAN, SAN and IPC connections are consolidated on a single Ethernet link. Each traffic type (BWG) is guaranteed the bandwidth it has been allocated and is prevented from usurping bandwidth from other types. However, if a BWG does not use its bandwidth, that bandwidth is made available to the other BWGs. The same holds for TCs within a BWG. If allocated some bandwidth, TCs are guaranteed to have it, and if unused, that bandwidth can be used by the other TCs within the BWG. Information regarding bandwidth allocation for some TCs might not be available. In the case of LAN, the entire allocation of bandwidth within the LAN link is typically undefined in today's networks. The arbitration scheme includes Group Strict Priorities (GSP) to cover for that. TCs for which the GSP bit is set are limited by the total throughput allocated to their BWG rather than to TC allocation.

Link bandwidth is divided among the BWGs for guaranteed minimum behavior. For example: LAN: 4 Gb/s, SAN: 4 Gb/s, IPC: 2 Gb/s. The X550 supports two types of bandwidth allocation within BWGs. TCs can be either allocated bandwidth or be used as in strict priority. If a TC does not use all of its allocated bandwidth, that bandwidth is recycled to other TCs in the BWG.

The X550 implements two replications of the weighted TC arbiter:

- One in the descriptor plane, arbitrating between the different descriptor queues, deciding which queue is serviced next. It is aimed to enforce the TC bandwidth allocation and prioritization scheme for a case when PCIe bandwidth is smaller than the link bandwidth.
- A second in the packet plane, at the output of the packet buffers, deciding which packet to transmit next. It is aimed to enforce the TC bandwidth allocation and prioritization scheme for a case when PCIe bandwidth is greater than the link bandwidth.

The condition for entry into the bandwidth allocation algorithm sequence differs for the descriptor and data arbiters:

- The descriptor arbiter queries whether there is at least one queue attached to a TC that is not empty, not switched off by the rate scheduler, with positive VM weighted arbiter credits (when relevant), and for which the destined packet buffer has room for the worst case maximum sized frame. This last condition is controlled by *RTTDCS.BPBFSM*.
- The packet arbiter queries whether the packet buffer has a packet to send and whether it is not stalled by priority flow control.

#### 7.6.2.4.1 Definition and Description of Parameters

**User Priority (UP):** There are eight traffic priorities, determined by 802.1p tag bits on an Ethernet link. The *Q-Tag* field holds UP's. Per 802.1p, Priority #7 is the highest priority. User priorities are assigned by the application or the system to certain usage classes, such as manageability, IPC control channel, VoIP. And additional bit within the VLAN TCI field (bit 5 - DEI) defines whether the packet has a no drop requirement. This bit is not being used by DCB mechanisms.

**User Bandwidth Group (UBWG):** A user bandwidth group is a management parameter that is a binding of user priorities into bandwidth groups for provisioning purposes. The hardware implementation does not recognize the UBWG entity.

**Traffic Class (TC):** Incoming packets are placed in traffic classes. Per the DCB functional specification, there might be a 1:1 mapping between UP and TC, or more than one priority can be grouped into a single class. Such grouping does not cross boundaries of traffic BWGs. The X550 implements eight or four TCs and maps them to UP's according to a programmable register. This provides the best flexibility for the IT manager. However, when more than one UP is mapped to the same TC, they must have the same no-drop policy network wide.

**Packet Buffer (PB):** TCs are mapped to packet buffers in a straightforward 1:1 mapping. Packets are also placed in packet buffers based on their class assignments.

**Traffic Bandwidth Group (BWG):** For bandwidth allocation and grouping, one or more TC can be grouped into a Traffic Bandwidth Group (BWG). A BWG is a logical association at a node, and has no markings inside a packet header. End stations and switches are independent in their definition and allocation of grouping of different TCs. Consistency of behavior throughout the network is handled by the UBWG provisioning mechanism.

One or more TCs can be grouped in a BWG. BWGs are allocated a percentage of bandwidth of available Ethernet link. The allocated bandwidth for BWG can be further divided among the TCs that are inside the BWG.

**Credits:** Credits regulate the bandwidth allocated to BWGs and TCs. As part of the WSP algorithm, each BWG and TC has pre-allocated credits. Those are decremented upon each transmission and replenished cyclically. The ratio between the credits of the BWGs represents the relative bandwidth percentage allocated to each BWG. The ratio between the credits of the TCs represents the relative bandwidth percentage allocated to each TC within a BWG. The X550 effectively maintains one table that represents both ratios at once. Note that credits can get negative values down to the maximum sized frame allowed on the TC.

**Maximum Credit Value** — The maximum credit value establishes a limit for the running sum of credits allotted to a class or group. This value prevents stacking up stale credits that can be added up over a relatively long period of time and then used by TCs all at once, altering fairness and latency.

**Note:** The absolute value of the credits has no direct bearing on the allocation of bandwidth. The ratio between the credits does. However, the absolute value might have substantial impact on the algorithm behavior. Larger absolute values can impact the latency of high priority queues and their ability to serve bursts with minimum latency, whereas too small credit values might

impact the correct functionality in presence of jumbo frames. The speed of the algorithm implementation should also be taken into account. The value of the maximum credit limit are also in principle not part of the main WSP algorithm. However, they impact the fairness of bandwidth reallocation between queues in case some queues do not transmit the full amount they have been permitted to. Also, small values prevent correct functionality of jumbo frames. From high-level simulations it appears that credits should be allocated as low as possible based on the speed of the algorithm. Maximum credit values for TCs should be 1.5x to 2x the size of the maximum entity expected in that TC.

**Weighted Strict Priority (WSP):** The algorithm implemented in the X550 for TC arbitration.

**Group Strict Priority (GSP):** Refer to the sections that follow for details.

**Link Strict Priority (LSP):** Refer to the sections that follow for details.

Table 7-53 (T2) defines the TCs, their association to BWGs and their bandwidth allocation. The following elements are defined in this table:

**Table 7-53. Bandwidth Allocation to TCs and BWGs**

| T2: Traffic Class Bandwidth Allocation Within a BWG |     |                   |                    |     |     |                                       |
|-----------------------------------------------------|-----|-------------------|--------------------|-----|-----|---------------------------------------|
| TC <sub>N</sub>                                     | BWG | TC Refill         | TC Max Credits     | LSP | GSP | TC Min Credits (according to GSP 0/1) |
| 0                                                   | 1   | 64 bytes to 32 KB | 64 bytes to 256 KB | 0/1 | 0/1 | -MSS / -2,048 KB                      |
| 1                                                   | 2   | 64 bytes to 32 KB | 64 bytes to 256 KB | 0/1 | 0/1 | -MSS / -2,048 KB                      |
| 2                                                   | 0   | 64 bytes to 32 KB | 64 bytes to 256 KB | 0/1 | 0/1 | -MSS / -2,048 KB                      |
| 3                                                   | 1   | 64 bytes to 32 KB | 64 bytes to 256 KB | 0/1 | 0/1 | -MSS / -2,048 KB                      |
| 4                                                   | 2   | 64 bytes to 32 KB | 64 bytes to 256 KB | 0/1 | 0/1 | -MSS / -2,048 KB                      |
| 5                                                   | 3   | 64 bytes to 32 KB | 64 bytes to 256 KB | 0/1 | 0/1 | -MSS / -2,048 KB                      |
| 6                                                   | 1   | 64 bytes to 32 KB | 64 bytes to 256 KB | 0/1 | 1/1 | -MSS / -2,048 KB                      |
| 7                                                   | 0   | 64 bytes to 32 KB | 64 bytes to 256 KB | 0/1 | 0/1 | -MSS / -2,048 KB                      |

† Due to a pipelined implementation, the TC credits range is enlarged by one MSS in both directions, beyond its positive and negative limits.

†† All values are implemented with 64-byte granularity (a value of one corresponds to 64 bytes of credit).

**TC:** Configuration — The traffic type associated to the packet buffer where incoming packets are kept before transmission (or discard — not implemented in transmit in the X550). TC7 is the highest priority TC.

**BWG:** Configuration — Traffic BWG that a TC belongs to.

**TC Credit Refill:** Configuration — The X550's WSP algorithm implements credit refill as the technique for traffic class percentage allocation. The credits refill are added to each TC credit count on each completion of the full round of the algorithm (after all TCs had their chance to send what they had in store and if they had credits for it).

The X550's driver needs to calculate the TC Credit refill to match the percentage allocated through management (in the MIB). The TC credit refill table includes, in one table both the TC and the BWG. Since the WSP arbitration is self timed, the ratio between the credits refill is the only defining parameter for the TC and BWG. The absolute values of the refill have significance as to the rate of distribution between the queues and can have impact on latency and on the momentary stability of the bandwidth fairness. Results from simulations indicate that the quantum for the refill should be small to prevent large swings. It should not be too small as to create overhead in the mechanism due to the execution time; however. The X550 allows a value of 64 bytes to 32 KB, A dynamic range of x500. The usage model is likely to call for a smallest refill value of 256 bytes to 512 bytes. This leaves a dynamic range

of 80x-200x. For example, if a queue is assigned 1% and this is translated into a 256-byte increment, another assigned with 99% would have a refill value of 25344 bytes.

**TC MaxCredit:** Configuration — To prevent use of stale credits, the number of credits each TC can accumulate upon refill is limited. The TC credit can only reach *MaxCredit*, beyond that its value gets recycled to other queues. Refer to the recycling mode for more details. The maximum range for the *MaxCredit* is 256 KB.

**Note:** Full testing of many values for maximum value is unnecessary. Hierarchical testing should be applied. For the random test, four to six values should be sufficient. It is important that the testing includes values that are relevant to the interesting zone of maximum value. For example, in the 0.8x to 2x the relevant largest entity in the class. Although class with an expected shorter packet could use a smaller *MaxCredit*, it is recommended that testing fully covers the cases where all the classes have similar values of *MaxCredit*, as it is a possible variant use of the algorithm.

**Link Strict Priority (LSP):** Configuration — If set, this bit specifies that this TC can transmit without any restriction of credits. This effectively means that this TC can take up the entire link bandwidth, unless preempted by higher priority traffic. If this bit is set, *TC.CreditRefill* must be set to 0b to ensure fair bandwidth allocation. Preferably, the algorithm implementation should disregard non-zero values in all its calculations.

**Group Strict Priority (GSP):** Configuration — This bit defines whether strict priority is enabled or disabled for this TC within its BWG. If *TC.GSP* is set to 1b, the TC is scheduled for transmission using strict priority. It does not check for availability of TC.Credits. It does check whether the BWG of this TC has credits (such as the amount of traffic generated from this TC is still limited by the BWG allocated for the BWG (T3. BWGP). If this bit is set, *TC.CreditRefill* values can be set to 0b, if a non-zero value is configured, TC credits are reduced first from the GSP TC and if reached to zero from other TCs in the group, if the refill credits are configured to zero the TC credits are reduced from the other TCs in the BWG.

**Note:** Since the *TC.GSP* parameter relates to individual TCs, some BWGs might have both TC's with bandwidth allocation and TC's with GSP. This is a hybrid usage mode that is complex to validate and is possibly secondary in importance.

**Usage Note —** It is possible that a TC using LSP dominates the link bandwidth if there are no packets waiting and eligible in higher priority TC's. To guarantee correct bandwidth allocation, all TC's with the unlimited bit set should be in the same traffic BWG (high priority group). Note that this is different than a typical DCB deployment considered where BWG is created with functional grouping, like LAN, SAN, and IPC etc. TC's with the *LSP* bit set should be the first to be considered by the scheduler (the first TC's). For example, from queue 7 to queue 5 with the other five TC's for groups with bandwidth allocation. These are not strict requirements, if these rules are not followed, undesirable behavior could occur in some cases. A group containing only TC's with the unlimited bit set effectively has zero BWG credits since TC's with the LSP unlimited bit set should have TC credits set to zero. Use of LSP / TC.GSP should be restricted to UP/TC's that service trusted applications.

**TC Credits:** Run-time parameter — TC credits is a running algebraic counter for each TC. It holds the number of available credits in 64-byte units. The algorithm runs sequentially between the TC's and enables transmission for those TCs that have positive pending credits. Note that credits can get negative values down to the maximum sized frame allowed on the TC.

**Table 7-54** (T3) defines the hierarchy of BWG similarly to T2 defining the hierarchy within the BWG's. T3 implementation should include eight rows.

**Table 7-54. Line Bandwidth Allocations to Bandwidth Groups (BWG) (with example)**

| T3: Line bandwidth allocation to Traffic Bandwidth Groups (BWG) |                              |                                  |              |               |
|-----------------------------------------------------------------|------------------------------|----------------------------------|--------------|---------------|
| BWG                                                             | BWG Refill Credits           | BWG MaxCredit                    | BWG Credit   | Description   |
| 0                                                               | = $\Sigma[TC]$ Credit Refill | = $\Sigma[TC]. \text{MaxCredit}$ | -/+ 2,048 KB | IPC           |
| 1                                                               | = $\Sigma[TC]$ Credit Refill | = $\Sigma[TC]. \text{MaxCredit}$ | -/+ 2,048 KB | SAN           |
| 2                                                               | = $\Sigma[TC]$ Credit Refill | = $\Sigma[TC]. \text{MaxCredit}$ | -/+ 2,048 KB | LAN           |
| 3                                                               | = $\Sigma[TC]$ Credit Refill | = $\Sigma[TC]. \text{MaxCredit}$ | -/+ 2,048 KB | Manageability |
| -                                                               |                              |                                  |              |               |
| -                                                               |                              |                                  |              |               |
| -                                                               |                              |                                  |              |               |
| 7                                                               |                              |                                  |              |               |

† Due to a pipelined implementation, the BWG credits range is enlarged by one MSS in both directions, beyond its positive and negative limits.

**BWG:** Configuration — This is the number of the traffic BWG that is three bits wide. This field corresponds to the *TC.BWG* field in [Table 7-53](#).

**BWG Refill Credits:** A virtual number — The credits provisioned for this BWG. The credits ratio between the BWG's should reflect the ratio of bandwidth between the BWG's. In the actual implementation, this number is the sum of the credit Refills of the TC's associated with this BWG.

**BWG MaxCredit:** A virtual number — The maximum credits for a BWG. Credits in the *BWG.Credit* counter are limited to this value. Credits that should have been refilled above this value are lost. In effect, due to the self-timed cyclic nature of the WSP algorithm, those credits are distributed between all BWG's. In the actual implementation, this number is the sum of the MaxCredit of the TC's associated with this BWG.

**BWG.Credit:** Run-time parameter — A running algebraic counter that is decremented for each transmission. At the end of each cycle, this counter is synchronized with the sum of the *TC.Credit* counter associated with this BWG. The synchronization algorithm depends on the recycling mode. refer to the sections that follow for details about arbitration configurations. Note that credits can get negative values down to the maximum sized frame allowed on the BWG.

#### 7.6.2.4.2 Arbiters Conventions

The WSP scheme previously described is written with the data plane arbiter in mind. However, the same scheme is used by the transmit descriptor plane arbiter and a subset of it is used by the receive data arbiter. To distinguish between the two arbiters, attributes of the each arbiter are prefixed as depicted in [Table 7-55](#).

**Table 7-55. Attributes of Tx Arbiters**

| Attribute        | Tx Packet Arbiter  | Tx Descriptor Arbiter |
|------------------|--------------------|-----------------------|
| TC               | P-TC               | D-TC                  |
| BWG              | P-BWG              | D-BWG                 |
| TC Credit Refill | P-TC Credit Refill | D-TC Credit Refill    |
| TC MaxCredit     | P-TC MaxCredit     | D-TC MaxCredit        |
| LSP              | P-LSP              | D-LSP                 |

**Table 7-55. Attributes of Tx Arbiters (Continued)**

| Attribute          | Tx Packet Arbiter    | Tx Descriptor Arbiter |
|--------------------|----------------------|-----------------------|
| GSP                | P-GSP                | D-GSP                 |
| TC Credits         | P-TC Credits         | D-TC Credits          |
| BWG Refill Credits | P-BWG Refill Credits | D-BWG Refill Credits  |
| BWG MaxCredits     | P-BWG MaxCredits     | D-BWG MaxCredits      |
| BWG Credits        | P-BWG Credits        | D-BWG Credits         |

Table 7-56 lists the register fields that contain the relevant attributes from Table 7-55.

**Table 7-56. Registers Allocation for Tx TC Arbiters**

| Attribute            | Tx Packet Arbiter | Tx Descriptor Arbiter |
|----------------------|-------------------|-----------------------|
| TC Control registers | RTTPT2C           | RTTDT2C               |
| BWG                  | BWG               | BWG                   |
| TC credit refill     | CRQ               | CRQ                   |
| TC MaxCredit         | MCL               | MCL                   |
| LSP                  | LSP               | LSP                   |
| GSP                  | GSP               | GSP                   |
| TC credits           | CCC               | CCC                   |

### 7.6.2.4.3 Tx TC WSP Arbitration Configurations

There are two parameters influencing the Tx TC WSP arbitration:

- RR/WSP
- Recycle mode

A separate set of configuration parameters exists for each of the three TC arbiters, as listed in Table 7-57.

**Table 7-57. Configuration Parameters for the Tx and Rx TC Arbiters**

| Parameter    | Tx Packet Arbiter | Tx Descriptor Arbiter | Rx Packet Arbiter |
|--------------|-------------------|-----------------------|-------------------|
|              | RTTPCS            | RTTDCS                | RTRPCS            |
| RR/WSP Mode  | TPPAC             | TDPAC                 | RAC               |
| Recycle Mode | TPRM              | TDRM                  | RRM               |

The impact of these settings on the arbitration is described in the sections that follow.

#### 7.6.2.4.3.1 RR/WSP

When this bit is set, the arbitration is in WSP mode. When reset, the arbitration is in flat frame-based round robin mode. In RR mode, one frame is transmitted from each packet buffer in its turn. BWG and TC parameters do not apply.

#### 7.6.2.4.3.2 Recycle Mode

**Architecture Overview of Recycle** — As a result of GSP transmits and TCs that reach their maximum credit limit, the credit count of a BWG might not match the total credit count of its TCs (refer to the sections that follow for more details). It is not merely an arithmetic issue. The WSP algorithm, dual hierarchy behaves as a maximum allocation algorithm within the BWG's and minimum allocation algorithm between the BWG's. Since the recycle is self timed, when a BWG does not transmit all of its allocated bandwidth within a cycle, at the end of the cycle its bandwidth is in effect reallocated to all BWG's. This results in a minimum allocation behavior. Inside the BWG's; however, this notion of self timing does not exist. Some explicit mechanism is required to recycle bandwidth within a BWG rather than to all the BWG's — The requirement to have a minimum allocation behavior.

- A BWG credit count might not match the total credit count of its TCs in the following cases:
  - **A TC is defined as GSP** — When a GSP is selected, the BWG credits are decremented but no TC is deducted. Therefore, the BWG credit count would be lower than the credit count of its TCs.
  - **Max credits during refill** — If a TC reaches its max credits value during refill, some credits are lost for that TC. However, the BWG for that TC is provided with the full refill count. Therefore, the BWG credit count would be higher than the credit count of its TCs.
- One bit per TC arbiter governs the recycle mode of the WSP algorithm:
  - **0: No Recycling** — At the end of each full arbitration cycle all TC's are refilled with their TC.Refill up to their TC.MaxCredits values. All BWG.Credit are loaded by the sum of the BWG TC.Credit.
  - **1: Recycle** — TC credits for TC's that have reached their maximum are recycled to other TC's of the BWG. The operation is calculated based on the BWG.Credit and the TC.Credits after their refill. The difference between them is the BWG.Recycle value.
    - **Positive BWG.Recycle** — The recycle algorithm adds credits from the BWG.Recycle to the TC.Credits starting from the highest priority TC in the BWG down, considering the TC.MaxCredit, until BWG.Recycle is zero.
    - **Negative BWG.Recycle** — The recycle algorithm subtracts credits from the BWG.Recycle to the TC.Credits starting from the lowest priority TC in the BWG up, until BWG.Recycle is zero.

#### 7.6.2.4.4 Tx TC WSP Arbiter Algorithm

The Transmit Packet Plane Arbitration Control (TPPAC) bit in the RTTPCS registers determines the scheduler type (RR or WSP).

**Strict Priority** — The strict-priority aspect of the TC WSP arbiter resides in the fact that once a TC has been granted for a data read request or for transmission, the highest priority TCs are checked (again) in a strict-priority order, starting from TC7, even if the granted TC still has credits for another data read request or transmission.

**Note:** The descriptor plane arbiter cannot issue a data read request unless there is an unused request for data. Therefore the arbiter stalls in its current state each time there are no data read requests available. The next arbitration decision is only done once there is at least one free data read request.

Figure 7-34. Tx TC WSP Arbiters Operation

## 7.6.3 Receive-Side Capabilities

### 7.6.3.1 User Priority to Traffic Class Mapping

To enable different TC support for incoming packets and proper behavior per TC, the X550's receive packet buffer is segmented into several packet buffers. The X550 supports the following configurations of packet buffer segmentation:

- DCB disabled — Single buffer of 384 KB
- DCB enabled with 4 TCs — 4 buffers, 96 KB each
- DCB enabled with 8 TCs — 8 buffers, 48 KB each
- DCB enabled with 8 TCs — 8 buffers, buffers 3:0 are 72 KB and buffers 7:4 are 24 KB

Incoming packets are transferred from the packet buffers into data buffers in system memory. Data buffers are arranged around descriptor rings described in [Section 7.1.5.5](#). Each descriptor queue is assigned dynamically to a given TC (and therefore to a packet buffer) as described in [Section 7.1.3](#).

Configuration registers:

- The size of each buffer is defined by the RXPBSIZE[0-7] registers. Note that it is possible to configure the buffers at 1 KB granularity.
- A received packet is assigned by the X550 to a TC, and is thus routed to the corresponding Rx packet buffer according to its *User Priority* field in the 802.1Q tag and according to a UP to TC mapping table loaded into the RTRUP2TC register.

**Caution:** Different UP to TC mappings can be loaded in each direction Tx and Rx, as per RTTUP2TC and RTRUP2TC registers, respectively. But in such a case, when a packet is looped back by the internal VM to VM switch, it is routed to the Rx packet buffer that corresponds to the TC that was used in Tx.

### 7.6.3.2 Rx PB Weighted Strict Priority Arbiter

The X550's Rx arbiter determines the order in which packets are written from the different packet buffers into system memory. Note that each packet buffer by itself is drained in the order packets arrived, as long as it deals with packets destined to the same Rx queue.

The arbitration algorithm between the receive packet buffers is WSP, similar to the TC scheme on the transmit side. Motivation for this scheme is as follows:

1. The major consideration is to prevent any delay in delivery of high-priority traffic.
2. Allocation of credits controls the bandwidth allocated to the different packet buffers.
3. A secondary mean of bandwidth allocation is the priority flow control. By altering the flow control high watermark, the X550 can effectively (if coarsely) regulate bandwidth allocation to types of traffic.

Table 7-58 (T4) defines the TCs and their bandwidth allocation. The following elements are defined in this table:

**Table 7-58. Bandwidth Allocation to Traffic Classes and Bandwidth Groups**

| T4: Packet Buffer Bandwidth Allocation Within a BWG |     |                   |                    |     |     |                                          |
|-----------------------------------------------------|-----|-------------------|--------------------|-----|-----|------------------------------------------|
| PB                                                  | BWG | PB Refill         | PB Max Credits     | LSP | GSP | PB Min Credits<br>(according to GSP 0/1) |
| 0                                                   | 1   | 64 bytes to 32 KB | 64 bytes to 256 KB | 0/1 | 0/1 | -MSS / -2,048 KB                         |
| 1                                                   | 2   | 64 bytes to 32 KB | 64 bytes to 256 KB | 0/1 | 0/1 | -MSS / -2,048 KB                         |
| 2                                                   | 0   | 64 bytes to 32 KB | 64 bytes to 256 KB | 0/1 | 0/1 | -MSS / -2,048 KB                         |
| 3                                                   | 1   | 64 bytes to 32 KB | 64 bytes to 256 KB | 0/1 | 0/1 | -MSS / -2,048 KB                         |
| 4                                                   | 2   | 64 bytes to 32 KB | 64 bytes to 256 KB | 0/1 | 0/1 | -MSS / -2,048 KB                         |
| 5                                                   | 3   | 64 bytes to 32 KB | 64 bytes to 256 KB | 0/1 | 0/1 | -MSS / -2,048 KB                         |
| 6                                                   | 1   | 64 bytes to 32 KB | 64 bytes to 256 KB | 0/1 | 0/1 | -MSS / -2,048 KB                         |
| 7                                                   | 0   | 64 bytes to 32 KB | 64 bytes to 256 KB | 0/1 | 0/1 | -MSS / -2,048 KB                         |

† Due to a pipelined implementation, the PB credits range is enlarged by one MSS in both directions, beyond its positive and negative limits.

†† All values are implemented with 64-byte granularity (a value of one corresponds to 64 bytes of credit).

Table 7-59 (T5) defines the hierarchy of BWG similarly to T4 defining the hierarchy within the BWG's. T4 implementation should include eight rows.

**Table 7-59. Packet Buffer Allocations to BWGs (with Example)**

| T5: Line Bandwidth Allocation to Traffic BWGs |                                     |                                   |              |             |
|-----------------------------------------------|-------------------------------------|-----------------------------------|--------------|-------------|
| BWG                                           | BWG Credit Refill                   | BWG MaxCredit                     | BWG Credit   | Description |
| 0                                             | = $\Sigma[\text{TC}]$ Credit Refill | = $\Sigma[\text{TC}]$ . MaxCredit | -/+ 2,048 KB | IPC         |
| 1                                             | = $\Sigma[\text{TC}]$ Credit Refill | = $\Sigma[\text{TC}]$ . MaxCredit | -/+ 2,048 KB | SAN         |
| 2                                             | = $\Sigma[\text{TC}]$ Credit Refill | = $\Sigma[\text{TC}]$ . MaxCredit | -/+ 2,048 KB | LAN         |
| 3                                             | = $\Sigma[\text{TC}]$ Credit Refill | = $\Sigma[\text{TC}]$ . MaxCredit | -/+ 2,048 KB | MGMT        |
| -                                             |                                     |                                   |              |             |
| -                                             |                                     |                                   |              |             |
| -                                             |                                     |                                   |              |             |
| 7                                             |                                     |                                   |              |             |

The attributes of the Rx packet arbiter are described in [Section 7.6.2.4.2](#).

### 7.6.3.2.1 Rx TC Arbitration Configurations

Table 7-60 lists the register fields that control the Rx arbiter.

**Table 7-60. Registers Allocation for DCB Rx Arbiters**

| Attribute            | Rx Packet Arbiter |
|----------------------|-------------------|
| PB Control registers | RTRPT4C           |
| PB Status registers  | RTRPT4S           |
| BWG                  | BWG               |
| PB credit refill     | CRQ               |
| PB MaxCredit         | MCL               |
| LSP                  | LSP               |
| GSP                  | GSP               |
| PB credits           | CCC               |

Configuration parameters for the Rx packet arbiter are defined and listed in [Section 7.6.2.4.1](#).

### 7.6.3.2.2 Rx TC WSP Arbiter Algorithm

The Rx packet arbiter operates in RR or WSP mode, configured through the RAC bit in the RTRPCS register. The WSP arbiter operation is described as follows.

Figure 7-35. Rx Packet WSP Arbiter Operation

## 7.7 Time SYNC (IEEE1588 and 802.1AS)

### 7.7.1 Overview

IEEE 1588 addresses the clock synchronization requirements of measurement and control systems. The protocol supports system-wide synchronization accuracy in the sub-microsecond range with minimal network and local clock computing resources. The protocol is spatially localized and allows simple systems to be installed and operate.

The IEEE802.1AS standard specifies the protocol used to ensure that synchronization requirements are met for time sensitive applications, such as audio and video, across Bridged and Virtual Bridged Local Area Networks consisting of LAN media where the transmission delays are almost fixed and symmetrical; for example, IEEE 802.3 full duplex links. This includes the maintenance of synchronized time during normal operation and following addition, removal, or failure of network components and network re-configuration. It specifies the use of IEEE 1588 specifications where applicable.

**Note:** The time sync mechanism activation is possible in full-duplex mode only and is not supported at 100 Mb/s link speed.

**Note:** The clock used for Time Sync is a 80 MHz clock, so the limit of the accuracy of all Time Sync operations is 12.5 ns.

### 7.7.2 Flow and Hardware/Software Responsibilities

The operation of a Precision Time Protocol (PTP) enabled network is divided into two stages: initialization and time synchronization.

At the initialization stage, every master-enabled node starts by sending sync packets that include the clock parameters of its clock. Upon receipt of a sync packet, a node compares the received clock parameters to its own and if the received parameters are better, then this node moves to a slave state and stops sending sync packets. While in slave state, the node continuously compares the incoming packet to its currently chosen master and if the new clock parameters are better, than the master selection is transferred to this master clock. Eventually the best master clock is chosen. Every node has a defined time-out interval that if no sync packet was received from its chosen master clock it moves back to a master state and starts sending sync packets until a new best master clock (PTP) is chosen.

The time synchronization stage is different to master and slave nodes. If a node is in a master state it should periodically send a sync packet that is time stamped by hardware on the Tx path (as close as possible to the PHY). After the sync packet, a Follow\_Up packet is sent that includes the value of the time stamp kept from the sync packet. In addition, the master should time stamp Delay\_Req packets on its Rx path and return to the slave that sent the time stamp value using a Delay\_Response packet. A node in a slave state should time stamp every incoming sync packet and if it came from its selected master, software uses this value for time offset calculation. In addition, it should periodically send Delay\_Req packets to calculate the path delay from its master. Every sent Delay\_Req packet sent by the slave is time stamped and kept. With the value received from the master with Delay\_Response packet, the slave can now calculate the path delay from the master to the slave. The synchronization protocol flow and the offset calculation are shown in [Figure 7-36](#).

**Figure 7-36. Sync Flow and Offset Calculation**

Hardware responsibilities are:

1. Identify the packets that require time stamping.
2. Time stamp the packets on both Rx and Tx paths.
3. Store the time stamp value for software.
4. Keep the system time in hardware and give a time adjustment service to software.
5. Maintain auxiliary features related to the system time.

Software responsibilities are:

1. Manageability controller protocol execution, which means defining the node state (master or slave) and selection of the master clock if in slave state.
2. Generate PTP packets, consume PTP packets.
3. Calculate the time offset and adjust the system time using a hardware mechanism for that.
4. Enable configuration and usage of the auxiliary features.

| Action                                                                             | Responsibility | Node Role |
|------------------------------------------------------------------------------------|----------------|-----------|
| Generate a sync packet with time stamp notification in the descriptor.             | Software       | Master    |
| Time stamp the packet and store the value in registers (T1).                       | Hardware       | Master    |
| Time stamp incoming sync packet, store the value in register                       | Hardware       | Slave     |
| Read the time stamp from register put in a Follow_Up packet and send.              | Software       | Master    |
| Once received, the Follow_Up store T2 from registers and T1 from Follow_up packet. | Software       | Slave     |
| Generate a Delay_Req packet with time stamp notification in the descriptor.        | Software       | Slave     |
| Time stamp the packet and store the value in registers (T3).                       | Hardware       | Slave     |
| Time stamp incoming Delay_Req packet, store the value in register                  | Hardware       | Master    |

| Action                                                                                    | Responsibility | Node Role |
|-------------------------------------------------------------------------------------------|----------------|-----------|
| Read the time stamp from register and send back to slave using a Delay_Response packet.   | Software       | Master    |
| Once received, the Delay_Response packet calculate offset using T1, T2, T3 and T4 values. | Software       | Slave     |

### 7.7.2.1 Time Sync Indications in Rx and Tx Packet Descriptors

Some indications need to be transferred between software and hardware regarding PTP packets. On the Tx path, software should set the 1588 bit in the Tx packet descriptor (bit 9). On the Rx path, hardware has two indications to transfer to software, one is to indicate that this packet is a PTP packet (whether time stamp is taken or not). This is also for other types of PTP packets needed for management of the protocol and this bit is set only for the L2 type of packets (the PTP packet is identified according to its Ethertype). PTP packets have the *L2 Packet* bit in the packet type field set (bit 11 in the receive descriptor) and the Ethertype matches the filter number set by software in the ETQF registers to filter PTP packets. The UDP type of PTP packets do not need such indication since the port number (319 for event and 320 all the rest PTP packets) directs the packets toward the time sync application. The second indication is *RDESC.STATUS.TS* (bit 16) to indicate to software that time stamp was taken for this packet. Software needs to access the time stamp registers to get the time stamp values.

## 7.7.3 Hardware Time Sync Elements

All time sync hardware elements are reset to their initial values (as defined in [Section 8.2.2.21](#)) upon Master reset. Upon change in link speed some of the time sync parameters should be changed accordingly.

### 7.7.3.1 System Time Structure and Mode of Operation

The *SYSTIME* is a 96 bit register is composed of: SYSTIMR, SYSTIMEL and SYSTIMEH registers: The SYSTIMR register holds the sub-nanosecond fraction, the SYSTIMEL register holds the nanosecond fraction and the SYSTIMEH register holds the sec fraction of the time (note that the upper two bits of the SYSTIMEL register are always zero while the max value of this register is 999,999,999 decimal).

- **Initial Setting** — Setting the initial time is done by direct write access to the *SYSTIME* register. Software should set first the SYSTIMEL and then set the SYSTIMEH. Setting the SYSTIMR is meaningless while it represents sub-nanosecond units.
- **Run Time** — During run time the *SYSTIME* timer value in the SYSTIMEH, SYSTIMEL and SYSTIMR registers, is updated periodically each 12.5 ns clock cycle according to the following formula:
  - Define: ***INC\_TIME* == 12.5 ns +/- *TIMINCA.Incvalue* \* 2<sup>-32</sup> ns**. Add or subtract the *TIMINCA.INCVALUE* is defined by *TIMINCA.ISGN* (where 0b means Add and 1b means Subtract)
  - Then: ***SYSTIME* = *SYSTIME* + *INC\_TIME***
- **Reading the *SYSTIME*** register by software is done by the following sequence:
  - Read the SYSTIMEL register.
  - Read the SYSTIMEH register.

- **Dynamic update of SYSTIME** registers is done by using the TIMADJ registers by the following flow:
  - Write the *TADJL* value and its *SIGN* to the TIMADJ register (the *SIGN* bit indicates if the *TADJL* value should be added or subtracted).
  - Following the write access to the TIMADJ register, the hardware repeats the following two steps at each 12.5 ns clock as long as the *Tadjust* > 0.
    - **$SYSTIME = SYSTIME + INC\_TIME + /- 1\text{ ns}$** . Add or subtract 1 ns is defined by TIMADJ.*Sign* (where '0' means Add and '1' means Subtract)
    - **$TADJL = TADJL - 1\text{ ns}$**
  - As shown above, the time adjustment might take multiple clocks. Software might write a new value to the TIMADJ register before the hardware completed the previous adjustment. In such a case, the new value written by software, overrides the above equation. If such a race is not desired, the software could check that the previous adjustment is completed by one of the following methods:
    - Wait enough time before accessing the TIMADJ register which guarantees that the previous update procedure is completed.
    - Poll the matched TSICR.*TADJ* flag which is set by the hardware each time the update procedure is completed.

### 7.7.3.2 Time Stamping Mechanism

The time stamping logic is located as close as possible to the PHY. Figure 7-37 shows the exact point in time where the time value is captured by the hardware relative to the packet content. This is to reduce delay uncertainties originated from implementation differences. As the time stamp is sampled at a very late phase in the data path, the X550 does not insert it to the transferred packet. Instead, the X550 supports the two-step operation as follows for Tx and Rx.

**Note:** As the time stamping logic is located at the MAC/PHY interface, there is no timestamping of packets when MAC loopback is activated.

Figure 7-37. Time Stamp Point

### 7.7.3.2.1 Single Tx Time Stamping

The time stamp logic is activated if enabled by the `TSYNCTXCTL.EN` bit and the time stamp bit in the packet descriptor is set. In this case, hardware captures the packet's transmission time in the `TXSTMPL` and `TXSTMPH` registers. Software is responsible to read the transmission time and append it in the `Folow_Up` packet as shown in [Figure 7-36](#).

### 7.7.3.2.2 Single Rx Time Stamping

On the Rx, this logic parses the traversing frame. If it is matching the message type defined in `RXMTRL` register and the `TSYNCRXCTL.TYPE` field, and timestamping is enabled by the `TSYNCRXCTL.EN` bit the reception time stamp is stored in the `RXSTMPL` and `RXSTMPH` registers. In addition, the TS status bits is reported in the Rx descriptor to identify that a time stamp was taken for this packet (stored in the `RXSTMPL` and `RXSTMPH` registers).

**Note:** The time stamp values are locked in the `RXSTMPL` and `RXSTMPH` registers until software accesses them. As long as software does not read these registers, hardware does not capture the time stamp of further Rx packets. To avoid potential deadlocks, it is recommended that software read the Rx time stamp registers at some time after sync or `Delay_Req` packets are expected. It would overcome erroneous cases on which the hardware latches a packet reception time while the packet's content was not posted properly to the software. Master software must not initiate consecutive sync requests before the previous response is received.

**Note:** If `TSYNCRXCTL.TYPE = 4` (sample time stamp of all packets), the timestamps are not locked in the `RXSTMPL` and `RXSTMPH` registers, and each new packet timestamp is stored in these registers.

### 7.7.3.2.3 Multiple Rx Time Stamping

Packets that are identified to be time stamped by hardware are also indicated by the `TS` or `TSIP` flags in the receive descriptors. If the `TS` flag is set, the packet reception time is sampled by the hardware in the `RXSTMPL/H` registers (see Single Rx Time Stamping above). These registers are locked till the software reads its value. If the `TSIP` flag is set, the packet reception time is posted to the packet buffer in host memory. For more information about posting the time stamp in the receive buffer refer to [Section 7.1.6.2](#).

## 7.7.4 Hardware Time Sync Elements

All time sync hardware is initialized as defined in the registers section upon MAC reset. The time sync logic is enabled if the `TSAUXC.Disable systime` flag is cleared.

The 1588 logic includes multiple registers larger than 32 bits which are indicated as `xxxL` (Low portion - LS) and `xxxH` (High portion - MS). When software accesses these registers (either read or write) it should access first the `xxxL` register (LS) and only then the `xxxH` register (MS). Accessing the `xxxH` might impact the hardware functionality which should be triggered only after both portions of the register are valid.

## 7.7.4.1 Target Time

The two target time registers TRGTTIMEL0/H0 and TRGTTIMEL1/H1 enable generating a time triggered event to external hardware using one of the SDP pins according to the setup defined in the TSSDP and TSAUXC registers. Each target time register is structured the same as the SYSTIMEL/H registers. If the value of SYSTIMEL/H is equal or larger than the value of the TRGTTIMEL/H registers, a change in level or a pulse is generated on the matched SDP outputs.

### 7.7.4.1.1 SYSTIM Synchronized Level Change Generation on SDP Pins

To generate a level change on one of the SDP pins when System Time (SYSTIM) reaches a pre-defined value, the driver should do the following:

1. Select a specific SDP pin by setting the TSSDP.TS\_SDPx\_EN flag to 1b (where 'x' is 0, 1, 2 or 3).
2. Assign a target time register to the selected SDP by setting the TSSDP.TS\_SDPx\_SEL field to 00b or 01b if level change should occur based on TRGTTIMEL0/H0 or TRGTTIMEL1/H1, respectively.
3. Define the selected SDPx pin as output, by setting the appropriate SDPx\_IODIR bit in the ESDP register (where 'x' is 0, 1, 2, or 3).
4. Define that this SDP is used for TimeSync function by setting the appropriate SDPx\_NATIVE bit in the ESDP register (while 'x' is 0, 1, 2, or 3). If used with SDP1, clear ESDP.SDP1\_FUNCTION field.
5. Program the target time TRGTTIMELx/Hx to the required event time (where 'x' is 0 or 1).
6. Program the TRGTTIMELx/Hx to "Level Change" mode by setting the TSAUXC.PLSG0 bit to 0b and TSAUXC.EN\_TTx bit to 1b (where 'x' is 0 or 1).
7. To make this a one time operation, the TSAUXC.DIS\_TS\_CLEAR field should be cleared.
8. When the SYSTIMEL/H registers become equal or larger than the selected TRGTTIML/H registers, the selected SDP changes its output level.

### 7.7.4.1.2 SYSTIM Synchronized Pulse Generation on SDP Pins

An output pulse can be generated by using one of the target time registers to define the beginning of the pulse and the other target time registers to define the pulse completion time. To generate a pulse on one of the SDP pins when System Time (SYSTIM) reaches a pre-defined value, the driver should do the following:

1. Select a specific SDP pin by setting the TSSDP.TS\_SDPx\_EN flag to 1b (where 'x' is 0, 1, 2 or 3).
2. Set TSSDP.TS\_SDPx\_SEL field to 00b to define that the TRGTTIMEL0/H0 register defines the start of pulse time, and the TRGTTIMEL1/H1 register defines the end of pulse time.
3. Define the selected SDPx pin as output, by setting the appropriate SDPx\_IODIR bit in the ESDP register (where 'x' is 0, 1, 2, or 3).
4. Define that this SDP is used for TimeSync function by setting the appropriate SDPx\_NATIVE bit in the ESDP register (where 'x' is 0, 1, 2, or 3). If used with SDP1, clear ESDP.SDP1\_FUNCTION field.
5. Program the target time TRGTTIMELx/Hx to the required event time (while 'x' is 0b or 1b).
6. TRGTTIMEL0/H0 should be set to a lower value than TRGTTIMEL1/H1.
7. Program the TRGTTIMEL0/H0 defined by the TSSDP.TS\_SDPx\_SEL to "Start of Pulse" mode by setting the TSAUXC.PLSG0 bit to 1b and TSAUXC.EN\_TT0 bit to 1b (where 'x' defines the SDP used). The TRGTTIMEL1/H1 register *should be set* to indicate the end of the pulse and TSAUXC.EN\_TT1 bit should be set to 1b.

8. To make this a one time operation, the `TSAUXC.DIS_TS_CLEAR` field should be cleared.
9. When the `SYSTIMEL/H` registers becomes equal or larger than the `TRGTTIMEL0/H0` registers the selected SDP changes its level. Then, when the `SYSTIMEL/H` registers becomes equal or larger than `TRGTTIMEL0/H1` registers (that define the trailing edge of the pulse), the selected SDP changes its level back.

#### 7.7.4.1.3 Synchronized Output Clock on SDP Pins

The X550 supports driving a programmable Clock on the SDP pins (up to two output clocks). The output clocks generated are synchronized to the global System time registers (`SYSTIM`). The Target Time registers (`TRGTTIMEL0/H0` or `TRGTTIMEL2/H1`) can be used for the clock output generation. To start an clock output on one of the SDP pins when System Time (`SYSTIM`) reaches a pre-defined value, the driver should do the following:

1. Select a specific SDP pin by setting the `TSSDP.TS_SDPx_EN` flag to 1b (where 'x' is 0, 1, 2 or 3).
2. Select the target time register for a selected SDP, by setting the `TSSDP.TS_SDPx_SEL` field to 10b or 11b if output clock should occur based on `TRGTTIMEL0/H0` or `TRGTTIMEL2/H1` respectively.
3. Program the matched `FREQOUT0/1` register to define clock half cycle time.
4. Define the selected SDPx pin as output, by setting the appropriate `SDPx_IODIR` bit in the `ESDP` register (where 'x' is 0, 1, 2, or 3).
5. Define that this SDP is used for TimeSync function by setting the appropriate `SDPx_NATIVE` bit in the `ESDP` register (where 'x' is 0, 1, 2, or 3). If used with `SDP1`, clear `ESDP.SDP1_FUNCTION` field.
6. If the output clock should start at a specific time, the `TSAUXC.ST0/1` flag should be set to 1b and the matched `TRGTTIMELx/Hx` should be set to the required start time.
7. Enable the clock operation by setting the relevant `TSAUXC.EN_CLK0/1` bit to 1b.

An interrupt can be generated from the clock output generated by the device by setting the relevant `TSAUXC.EN_TT0/1` bit to 1b and by setting the `TSAUXC.DIS_TS_CLEAR` to allow it to work continuously. The clock out drives initially a logical '0' level on the selected SDP. If the `TSAUXC.ST0/1` flag is cleared, it happens instantly when setting the `TSAUXC.EN_CLK0/1` bit. Otherwise it happens when `SYSTIM` is equal or larger than the `TRGTTIM`. Since then, the hardware repeats endlessly the following two steps:

1. Increment the used `TRGTTIMELx/Hx` by `FREQOUT`.
2. When `SYSTIM` is equal or larger than the `TRGTTIM`, the SDP reverts its output level.

**Note:** When clearing `TSAUXC.EN_CLK0/1` while `TSAUXC.EN_TT0/1` was set to generate interrupts, clear the matching `TSAUXC.EN_TT0/1` too to avoid one unexpected toggle.

#### 7.7.4.2 Time Stamp Events

Upon a change in the input level of one of the SDP pins that was configured to detect Time stamp events using the `TSSDP` register or upon a setting of one of the `TSAUXC.SAMP_AUTx` fields, a time stamp of the system time is captured into one of the two auxiliary time stamp registers (`AUXSTMPL0/H0` or `AUXSTMPL1/H1`). Software enables the timestamp of input event as follows:

1. Define the sampled SDP on AUX time 'x' ('x' = 0b or 1b) by setting the `TSSDP.AUXx_SDP_SEL` field while setting the matched `TSSDP.AUXx_TS_SDP_EN` bit to 1b.
2. Set also the `TSAUXC.EN_TSx` bit ('x' = 0b or 1b) to 1b to enable "timestamping".

Following a transition on the selected SDP, the hardware does the following:

1. The SYSTIM registers (low and high) are latched to the selected AUXSTMP registers (low and high).
2. The selected *AUTT0* or *AUTT1* flags are set in the TSICR and TSAUXC registers. If the *AUTT* interrupt is enabled by the TSIM register, and the 1588 interrupts are enabled by the *TIMESYNC* flag in the ICR register, an interrupt is asserted as well. After the hardware reports that an event time was latched, the software should read the latched time in the selected AUXSTMP registers. Software should read first the Low register and only then the High register. Reading the high register clears the relevant TSAUC.*AUTT*x field and releases the registers to sample a new event.

The software device driver may initiate a sampling of the current time by setting one of the TSAUXC.*SAMP\_AUT*x fields. When one of these bits is written the hardware The SYSTIM registers (low and high) are latched to the selected AUXSTMP registers (low and high) and the selected *AUTT0* or *AUTT1* flags are set in the TSAUXC register. Once the device driver reads the selected AUXSTMP registers as described above, the hardware clears the relevant TSAUXC.*AUTT*x field and releases the registers to sample a new event.

## 7.7.5 Time Sync Interrupts

Time Sync related interrupts can be generated by programming the TSICR and TSIM registers. The TSICR register logs the interrupt cause and the TSIM register enables masking specific TSICR bits. Occurrence of a Time Sync interrupt sets the ICR.TIME\_SYNC interrupt bit.

## 7.7.6 PTP Packet Structure

The time sync implementation supports both the 1588 V1 and V2 PTP frame formats. The V1 structure can come only as UDP payload over IPv4 while the V2 can come over L2 with its Ethertype or as a UDP payload over IPv4 or IPv6. The 802.1AS uses only the layer 2 V2 format. Note that PTP frame structure over UDP is not supported in the X550 for IP tunneling packets.

| Offset in Bytes | V1 Fields         | V2 Fields                      |                    |
|-----------------|-------------------|--------------------------------|--------------------|
| Bits            | 7 6 5 4 3 2 1 0   | 7 6 5 4 3 2 1 0                |                    |
| 0               | <b>versionPTP</b> | transportSpecific <sup>1</sup> | <b>messageType</b> |
| 1               |                   | Reserved                       | <b>versionPTP</b>  |
| 2               | versionNetwork    | messageLength                  |                    |
| 3               |                   |                                |                    |

| Offset in Bytes | V1 Fields                       | V2 Fields             |
|-----------------|---------------------------------|-----------------------|

| 29              |                                 |                       |
| 30              | <b>sequenceId</b>               | <b>sequenceId</b>     |
| 31              |                                 |                       |
| 32              | <b>control</b>                  | control               |
| 33              | reserved                        | logMessagePeriod      |
| 34              | falgs                           | n/a                   |
| 35              |                                 |                       |

1. Should all be zero.

**Note:** Only the fields with the bold italic format colored red are of interest to hardware.

|               |                 |               |             |
|---------------|-----------------|---------------|-------------|
| Ethernet (L2) | VLAN (Optional) | PTP Ethertype | PTP message |
| Ethernet (L2) | IP (L3)         | UDP           | PTP message |

When a PTP packet is recognized (by Ethertype or UDP port address) on the Rx side, the version should be checked if it is V1, then the control field at offset 32 should be compared to message field in the RXMTRL register described in [Section 8.2.2.21.2](#). Otherwise, the byte at offset 0 should be used for comparison to the rest of the needed field are at the same location and size for both V1 and V2.

| Enumeration            | Value |
|------------------------|-------|
| PTP_SYNC_MESSAGE       | 0     |
| PTP_DELAY_REQ_MESSAGE  | 1     |
| PTP_FOLLOWUP_MESSAGE   | 2     |
| PTP_DELAY_RESP_MESSAGE | 3     |
| PTP_MANAGEMENT_MESSAGE | 4     |
| reserved               | 5-255 |

| MessageId                       | Message Type | Value (hex) |
|---------------------------------|--------------|-------------|
| PTP_SYNC_MESSAGE                | Event        | 0           |
| PTP_DELAY_REQ_MESSAGE           | Event        | 1           |
| PTP_PATH_DELAY_REQ_MESSAGE      | Event        | 2           |
| PTP_PATH_DELAY_RESP_MESSAGE     | Event        | 3           |
| Unused                          |              | 4-7         |
| PTP_FOLLOWUP_MESSAGE            | General      | 8           |
| PTP_DELAY_RESP_MESSAGE          | General      | 9           |
| PTP_PATH_DELAY_FOLLOWUP_MESSAGE | General      | A           |
| PTP_ANNOUNCE_MESSAGE            | General      | B           |
| PTP_SIGNALLING_MESSAGE          | General      | C           |
| PTP_MANAGEMENT_MESSAGE          | General      | D           |
| Unused                          |              | E-F         |

If V2 mode is configured in TSAUXC register ([Section 8.2.2.21.13](#)), time stamp should be taken on PTP\_PATH\_DELAY\_REQ\_MESSAGE and PTP\_PATH\_DELAY\_RESP\_MESSAGE for any value in the message field in the RXMTRL register described at [Section 8.2.2.21.2](#).

**Note:** A PTP over UDP packet encapsulated in a VXLAN or NVGRE tunnel is still identified as a PTP packet.

## 7.7.6.1 Time Sync Packets Identification Configuration

Table 7-61 summarize the setting needed to identify Time Sync packets.

**Table 7-61. Enabling Receive Timestamp**

| Functionality                                         | Register   | Field                                       | Setting Options                                                                                                                                                                                                                                                                                                             |
|-------------------------------------------------------|------------|---------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Enable receive timestamp in register                  | TSYNCRXCTL | En                                          | En = 1b (must be set in all the following options).                                                                                                                                                                                                                                                                         |
| Sampled V1 Control value                              | RXMTRL     | CTRLT                                       | The <i>CTRLT</i> defines the recognized V1 <i>Control</i> field. This field must be defined if V1 packets recognition is required.<br>0x0 = PTP_SYNC_MESSAGE                                                                                                                                                                |
| Sampled V2 MessageType value                          | RXMTRL     | MSGT                                        | The <i>MSGT</i> defines the recognized V2 <i>MessageType</i> field. This field must be defined if V2 packets recognition is required.<br>0x0 = Sync                                                                                                                                                                         |
| Enable all packets for timestamp                      | TSYNCRXCTL | Type                                        | Type equals to 100b enables sampling all packets. Useful only when posting the timestamp to the packet buffer in host memory, enabled per queue by the <i>SRRCTL[n].Timestamp</i> .                                                                                                                                         |
| Enable L2 1588 packets for timestamp sampling         | TSYNCRXCTL | Type                                        | Type equals to 000b or 010b enable V2 packets with <i>MessageType</i> equals to <i>MSGT</i><br>Type equals to 101b enable all V2 packets with <i>Message</i> Type bit 3 zero (means any event packets)                                                                                                                      |
|                                                       | ETQF[n]    | EType Filter enable<br>IEEE_1588_TIME_STAMP | The EType on one of the enabled ETQF registers (Filter enable is '1') should be set to the 1588 EtherType (equals to 0x88F7) and <i>IEEE_1588_TIME_STAMP</i> field should be set.                                                                                                                                           |
| Enable 1588 packets over UDP for timestamp sampling   | TSYNCRXCTL | Type                                        | Type equals to 001b enables V1 packets with <i>Control</i> field equals to <i>CTRLT</i> parameter<br>Type equals to 010b enables V2 packets with <i>MessageType</i> fields equals to <i>MSGT</i> parameter<br>Type equals to 101b enables all V2 packets with <i>MessageType</i> bit 3 zero (which means any event packets) |
|                                                       | RXMTRL     | UDPT                                        | Defines the UDP port to use for V1 detection                                                                                                                                                                                                                                                                                |
| Define specific receive queue for the L2 1588 packets | ETQF[n]    | Rx Queue<br>Queue Enable                    | Setting the "Queue Enable" on the same ETQF register as above, the receive queue is defined by the <i>Rx Queue</i> field.                                                                                                                                                                                                   |

## 7.8 Virtualization

### 7.8.1 Overview

I/O virtualization is a mechanism that can be used to share I/O resources among several consumers. For example, in a virtual system, multiple operating systems are loaded and each operates as though the entire system's resources were at its disposal. However, for the limited number of I/O devices, this presents a problem because each operating system might be in a separate memory domain and all the data movement and device management has to be done by a Virtual Machine Monitor (VMM). VMM access adds latency and delay to I/O accesses and degrades I/O performance. Virtualized devices are designed to reduce the burden of the VMM by making certain functions of an I/O device shared among multiple guest operating systems or a Virtual Machine (VM), thereby allowing each VM direct access to the I/O device.

The X550 supports two modes of operations of virtualized environments:

1. Direct assignment of part of the port resources to different guest operating systems using the PCI SIG SR IOV standard. Also known as native mode or pass-through mode. This mode is referenced as **IOV mode** throughout this section.
2. Central management of the networking resources by an IOVM or by the VMM. Also known as software switch acceleration mode. This mode is referred to as **VMDq2 mode in this section**.

The virtualization offloads capabilities provided by the X550 apart from the replication of functions defined in the PCI SIG IOV specification are part of **VMDq2**.

A hybrid model, where part of the VMs are assigned a dedicated share of the port and the rest are serviced by an IOVM is also supported. However, in this case the offloads provided to the software switch might be more limited. This model can be used when parts of the VMs run operating systems for which VF drivers are available and thus can benefit from an IOV and others that run older operating systems for which VF drivers are not available and are serviced by an IOVM. In this case, the IOVM is assigned one VF and receives all the packets with Ethernet MAC Addresses of the VMs behind it.

The following section describes the support the X550 provides for these modes.

This section assumes a single-root implementation of IOV and no support for multi-root.

#### 7.8.1.1 Direct Assignment Model

The direct assignment support in the X550 is built according to the following model of the software environment.

It is assumed that one of the software drivers sharing the port hardware behaves as a master driver (**Physical Function** or **PF** driver). This driver is responsible for the initialization and the handling of the common resources of the port. All the other drivers (**Virtual Function** drivers or **VF** drivers) might read part of the status of the common parts but cannot change them. The PF driver might run either in the VMM or in some service operating system. It might be part of an IOVM or part of a dedicated service operating system.

In addition, part of the non time-critical tasks are also handled by the PF driver. For example, access to CSR through the I/O space or access to the configuration space are available only through the master interface. Time-critical CSR space like control of the Tx and Rx queue or interrupt handling is replicated per VF, and directly accessible by the VF driver.

**Note:** In some systems with a thick hypervisor, the service operating system might be an integral part of the VMM. For these systems, each reference to the service operating system in the sections that follow refer to the VMM.

#### 7.8.1.1.1 Rationale

The direct assignment model enables each of the VMs to receive and transmit packets with minimum of overhead. Non time-critical operations such as initialization and error handling can be done via the PF driver. In addition, it is important that the VMs can operate independently with minimal disturbance. It is also preferable that the VM interface to hardware should be as close as possible to the native interface in non-virtualized systems to minimize the software development effort.

The main time critical operations that require direct handling by the VM are:

- Maintenance of the data buffers and descriptor rings in host memory. To support this, the DMA accesses of the queues associated to a VM should be identified as such on the PCIe using a different requester ID.
- Handling of the hardware ring (tail bump and head updates)
- Interrupts handling

The capabilities needed to provide independence between VMs are:

- Per-VM reset and enable capabilities
- Tx rate control
- Allocating separate CSR space per VM. This CSR space is organized as close as possible to the regular CSR space to enable sharing of the base driver code.

**Note:** The rate control and VF enable capabilities are controlled by the PF.

#### 7.8.1.2 System Overview

The following drawings show the various elements involved in the I/O process in a virtualized system. [Figure 7-38](#) shows the flow in software VMDq2 mode and [Figure 7-39](#) shows the flow in IOV mode.

This section assumes that in IOV mode, the driver on the guest operating system is aware that it operates in a virtual system (para-virtualized) and there is a channel between each of the VM drivers and the PF driver allowing message passing such as configuration request or interrupt messages. This channel can use the mailbox system implemented in the X550 or any other means provided by the VMM vendor.

**Figure 7-38. System Configuration for VMDq2 Mode**

Figure 7-39. System Configuration for IOV Mode

## 7.8.2 PCI-SIG SR-IOV Support

### 7.8.2.1 SR-IOV Concepts

SR-IOV defines the following entities in relation to I/O virtualization:

- **Virtual Image (VI)** — Part of the I/O resources are assigned to a VM.
- **I/O Virtual Intermediary (IOVI) or I/O Virtual Machine (IOVM)** — A special VM that owns the physical device and is responsible for the configuration of the physical device.
- **Physical function (PF)** — A function representing a physical instance — One port for the X550. The PF driver is responsible for the configuration and management of the shared resources in the function.
- **Virtual Function (VF)** — A part of a PF assigned to a VI.

### 7.8.2.2 Configuration Space Replication

The SR-IOV specification defines a reduced configuration space for the virtual functions. Most of the PCIe configuration of the VFs comes from the PF.

This section describes the expected handling of the different parts of the configuration space for virtual functions. It deals only with the parts relevant to the X550.

Details of the configuration space for virtual functions can be found in [Section 9.3](#).

#### 7.8.2.2.1 Legacy PCI Configuration Space

The legacy configuration space is allocated to the PF only and emulated for the VFs. A separate set of BARs and one bus master enable bit is allocated in the SR-IOV capability structure in the PF and is used to define the address space used by the entire set of VFs.

All the legacy error reporting bits are emulated for the VF. See [Section 7.8.2.4](#) for details.

#### 7.8.2.2.2 Memory BARs Assignment

The SR-IOV specification defines a fixed stride for all the VF BARs, so that each VF can be allocated part of the memory BARs at a fixed stride from a basic set of BARs. In this method, only two decoders per replicated BAR per PF are required and the BARs reflected to the VF are emulated by the VMM.

The only BARs that are useful for the VFs are BAR0 and BAR3, so only those are replicated. [Table 7-62](#) lists the existing BARs and the stride used for the VFs:

**Table 7-62. BARs in the X550 (64-bit BARs)**

| BAR  | Type | Usage     | Requested Size per VF (=Stride)                                                                   |
|------|------|-----------|---------------------------------------------------------------------------------------------------|
| 0, 1 | Mem  | CSR space | Maximum (16 KB, page size). For page size see <a href="#">Section 9.2.4.4.8</a> for more details. |
| 2    | n/a  | Not used  | N/A                                                                                               |
| 3, 4 | Mem  | MSI-X     | Maximum (16 KB, page size).                                                                       |
| 5    | n/a  | Not used  | N/A                                                                                               |

BAR0 of the VFs are a sparse version of the original PF BAR and include only the register relevant to the VF. For more details see [Section 7.8.2.7](#).

Figure 7-40 shows the different BARs in an IOV-enabled system:

**Figure 7-40. BARs in an IOV-enabled System**

### 7.8.2.2.3 PCIe Capability Structure

The PCIe capability structure is shared between the PF and the VFs. The only relevant bits that are replicated are:

- Transaction pending.
- Function Level Reset (FLR). See [Section 7.8.2.3](#) for details.

### 7.8.2.2.4 MSI and MSI-X Capabilities

Both MSI and MSI-X are implemented in the X550. MSI-X vectors can be assigned per VF. MSI is not supported for the VFs.

See [Table 9-16](#) for more details of the MSI-X and PBA tables implementation.

### 7.8.2.2.5 VPD Capability

VPD is implemented only once and is accessible only from the PF.

### 7.8.2.2.6 Power Management Capability

The X550 does not support power management per VF. The power management registers exist for each VF, but only the D0 power state is supported.

### 7.8.2.2.7 Serial ID

Serial ID capability is not exposed in VFs.

### 7.8.2.2.8 Error Reporting Capabilities (Advanced and Legacy)

All the bits in this capability structure are implemented only for the PF. Note that the VMs see an emulated version of this capability structure. See [Section 7.8.2.4](#) for details.

### 7.8.2.3 FLR Capability

The *FLR* bit is required per VF. Setting of this bit resets only a part of the logic dedicated to the specific VF and does not influence the shared part of the port. This reset should disable the queues, disable interrupts and the stop receive and transmit process per VF.

Setting the PF *FLR* bit resets the entire function.

### 7.8.2.4 Error Reporting

Error reporting includes legacy error reporting and Advanced Error Reporting (AER) or role-based capability.

The legacy error management includes the following functions:

- **Error capabilities enablement** — These are set by the PF for all the VFs. Narrower error reporting for a given VM can be achieved by filtering of the errors by the VMM. This includes:
  - SERR# Enable
  - Parity Error Response
  - Correctable Reporting Enable
  - Non-Fatal Reporting Enable
  - Fatal Reporting Enable
  - UR Reporting Enable
- **Error status in the configuration space** — These should be set separately for each VF. This includes:
  - Master Data Parity Error
  - Signaled Target Abort
  - Received Target Abort
  - Master Abort
  - SERR# Asserted
  - Detected Parity Error
  - Correctable Error Detected
  - Non-Fatal Error Detected
  - Unsupported Request Detected

AER capability includes the following functions:

- **Error capabilities enablement** — The *Error Mask*, and *Severity* bits are set by the PF for all the VFs. Narrower error reporting for a given VM can be achieved by filtering of the errors by the VMM. These includes:
  - Uncorrectable Error Mask Register
  - Uncorrectable Error Severity Register
  - Correctable Error Mask Register
  - ECRC Generation Enable
  - ECRC Check Enable
- **Non-Function Specific Errors Status in the configuration space**
  - Non-Function Specific Errors are logged in the PF
  - Error logged in one register only
  - VI avoids touching all VFs to clear device level errors
  - The following errors are not function specific
    - All Physical Layer errors
    - All Link Layer errors
    - ECRC Fail
    - UR, when caused by no function claiming a TLP
    - Receiver Overflow
    - Flow Control Protocol Error
    - Malformed TLP
    - Unexpected Completion
- **Function Specific Errors Status in the configuration space**
  - Allows Per-VF error detection and logging
  - Help with fault isolation
  - The following errors are function specific
    - Poisoned TLP received
    - Completion Timeout
    - Completer Abort
    - UR, when caused by a function that claims a TLP
    - ACS Violation
- **Error logging** — Each VF has it's own header log.
- **Error messages** — To ease the detection of the source of the error, the error messages should be emitted using the requester ID of the VF in which the error occurred.

## 7.8.2.5 Alternative Routing ID (ARI) and IOV Capability Structures

To allow more than eight functions per end point without requesting an internal switch, as usually needed in virtualization scenarios, the PCI-SIG defines the ARI capability structure. This is a new capability that enables an interpretation of the *Device* and *Function* fields as a single identification of a function within the bus. In addition, a new structure used to support the IOV capabilities reporting and control is defined. Both structures are described in sections [Section 9.2.4.3](#) and [Section 9.2.4.4](#). Refer to the following section for details on the Requester ID (RID) allocation to VFs.

## 7.8.2.6 RID Allocation

RID allocation of the VF is done using the *Offset* field in the IOV structure. This field should be replicated per VF and is used to do the enumeration of the VFs.

Each PF includes an offset to the first associated VF. This pointer is a relative offset to the Bus/Device/Function (BDF) of the first VF. The *Offset* field is added to PF's requester ID to determine the requester ID of the next VF. An additional field in the IOV capability structure describes the distance between two consecutive VF's requester IDs.

### 7.8.2.6.1 Bus Device Function Layout

#### 7.8.2.6.1.1 ARI Mode

ARI allows interpretation of the device ID part of the RID as part of the function ID inside a device. Thus, a single device can span up to 256 functions. To ease the decoding, the least significant bit of the function number points to the physical port number. The *Next* bits indicate the VF number. [Table 7-63](#) lists the VF RIDs.

The layout of RID's used by the X550 is reported to the operating system via the PCIe IOV capability structure. See [Section 9.2.4.4.6](#).

**Table 7-63. RID per VF — ARI Mode**

| Port | VF# | B,D,F          | Binary      | Notes                              |
|------|-----|----------------|-------------|------------------------------------|
| 0    | PF  | B,0,0          | B,00000,000 | PF                                 |
| 1    | PF  | B,0,1          | B,00000,001 | PF                                 |
| 0    | 1   | <b>B</b> ,16,0 | B,10000,000 | Offset to first VF from PF is 128. |
| 1    | 1   | <b>B</b> ,16,1 | B,10000,001 |                                    |
| 0    | 2   | <b>B</b> ,16,2 | B,10000,010 |                                    |
| 1    | 2   | <b>B</b> ,16,3 | B,10000,011 |                                    |
| 0    | 3   | <b>B</b> ,16,4 | B,10000,100 |                                    |
| 1    | 3   | <b>B</b> ,16,5 | B,10000,101 |                                    |
| ...  |     |                |             |                                    |
| 0    | 64  | <b>B</b> ,31,6 | B,11111,110 |                                    |
| 1    | 64  | <b>B</b> ,31,7 | B,11111,111 | Last                               |

### 7.8.2.6.1.2 Non-ARI Mode

When ARI is disabled, non-zero devices in the first bus cannot be used, thus a second bus is needed to provide enough RIDs. In this mode, the RID layout is as follows:

**Table 7-64. RID per VF — Non-ARI Mode**

| Port | VF# | B,D,F            | Binary        | Notes                              |
|------|-----|------------------|---------------|------------------------------------|
| 0    | PF  | B,0,0            | B,00000,000   | PF                                 |
| 1    | PF  | B,0,1            | B,00000,001   | PF                                 |
| 0    | 0   | <b>B+1</b> ,16,0 | B+1,10000,000 | Offset to first VF from PF is 384. |
| 1    | 0   | <b>B+1</b> ,16,1 | B+1,10000,001 |                                    |
| 0    | 1   | <b>B+1</b> ,16,2 | B+1,10000,010 |                                    |
| 1    | 1   | <b>B+1</b> ,16,3 | B+1,10000,011 |                                    |
| 0    | 2   | <b>B+1</b> ,16,4 | B+1,10000,100 |                                    |
| 1    | 2   | <b>B+1</b> ,16,5 | B+1,10000,101 |                                    |
| ...  |     |                  |               |                                    |
| 0    | 63  | <b>B+1</b> ,31,6 | B+1,11111,110 |                                    |
| 1    | 63  | <b>B+1</b> ,31,7 | B+1,11111,111 | Last                               |

**Note:** When the device ID of a physical function changes (because of LAN disable or LAN function select settings), the VF device IDs changes accordingly.

## 7.8.2.7 Hardware Resources Assignment

The main resources to allocate per VM are queues and interrupts. The assignment is static. If a VM requires more resources, it might be allocated to more than one VF. In this case, each VF gets a specific Ethernet MAC Address/VLAN tag to enable forwarding of incoming traffic. The two VFs are then teamed in software.

### 7.8.2.7.1 PF Resources

A possible use of the PF is for a configuration setting without transmit and receive capabilities. In this case, it is not allocated to any queues but is allocated to one MSI-X vector.

The PF has access to all the resources of all VMs, but it is not expected to make use of resources allocated to active VFs.

### 7.8.2.7.2 Assignment of Queues to VF

See [Section 7.2.1.2.1](#) for allocating Tx queues.

See [Section 7.1.3.2](#) for allocating Rx queues.

[Table 7-65](#) lists the Tx and Rx queues to VF allocation.

**Table 7-65. Queue to VF Allocation**

| VF  | Queues in 16 VMs Mode | Queues in 32 VMs Mode | Queues in 64 VMs Mode |
|-----|-----------------------|-----------------------|-----------------------|
| 0   | 0-7                   | 0-3                   | 0-1                   |
| 1   | 8-15                  | 4-7                   | 2-3                   |
| ... | ...                   | ...                   | ...                   |
| 15  | 120-127               | ...                   | ...                   |
| ... |                       | ...                   | ...                   |
| 31  |                       | 124-127               | ...                   |
| ... |                       |                       | ...                   |
| 63  |                       |                       | 126-127               |

### 7.8.2.7.3 Assignment of MSI-X Vector to VF

See [Section 7.3.4.3](#) for allocating MSI-X vectors in IOV mode.

### 7.8.2.8 CSR Organization

CSRs can be divided into three types:

- Global Configuration registers that should be accessible only to the PF — For example, link control and LED control. These types of registers also include all of the debug features such as the mapping of the packet buffers and is responsible for most of the CSR area requested by the X550. This includes per VF configuration parameters that can be set by the PF without performance impact.
- Per-VF parameters — For example, per VF reset, interrupt enable, etc. Multiple instances of these parameters are used only in an IOV system and only one instance is needed for non IOV systems.
- Per-queue parameters that should be replicated per queue — For example, head, tail, Rx buffer size, TPH tag, etc. These parameters are used by both a VF in an IOV system and by the PF in a non-IOV mode.

To support IOV without distributing the current drivers operation in legacy mode, the following method is used:

- The PF instance of BAR0 continues to contain the legacy and control registers. It is accessible only to the PF. The BAR enables access to all the resources including the VF queues and other VF parameters. However, it is expected that the PF driver does not access these queues in IOV mode.
- The VF instances of BAR0 provide control on the VF specific registers. These BARs have the same mapping as the original BAR0 with the following exceptions:
  - Fields related to the shared resources are reserved.
  - The queues assigned to a VF are mapped at the same location as the first same number of queues of the PF.
- Assuming some backward compatibility is needed for IOV drivers, The PF/VF parameters block should contain a partial register set as described in VF Device Registers section.

## 7.8.2.9 SR IOV Control

To control the IOV operation, the physical driver is provided with a set of registers. These include:

- The mailbox mechanism described in the next section.
- The switch and filtering control registers described in [Section 7.8.3.9](#).
- PFVFLREC register indicating that a VFLR reset occurred in one of the VFs (bitmap).

### 7.8.2.9.1 VF-to-PF Mailbox

The VF drivers and the PF driver require some means of communication between them. This channel can be used for the PF driver to send status updates to the VFs (such as link change, memory parity error, etc.) or for the VF to send requests to the PF (add to VLAN).

Such a channel can be implemented in software, but requires enablement by the VMM vendors. To avoid the need for such an enablement, the X550 provides such a channel that enables direct communication between the two drivers.

The channel consists of a mailbox. Each driver can then receive an indication (either poll or interrupt) when the other side wrote a message.

Assuming a maximum message size of 64 bytes (one cache line), a memory of 64 bytes x 64 VMs = 4 KB is provided per port. The RAM is organized as follows:

**Table 7-66. Mailbox Memory**

| RAM Address          | Function    | PF BAR 0 Mapping <sup>1</sup> | VF BAR 0 Mapping <sup>2</sup> |
|----------------------|-------------|-------------------------------|-------------------------------|
| 0 — 63               | VF0 <-> PF  | 0 — 63                        | VF0 + MBO                     |
| 64 — 127             | VF1 <-> PF  | 64 — 127                      | VF1 + MBO                     |
| ....                 |             |                               |                               |
| (4 KB-64) — (4 KB-1) | VF63 <-> PF | (4 KB-64) — (4 KB-1)          | VF63 + MBO                    |

1. Relative to mailbox offset.

2. MBO = mailbox offset in VF CSR space.

In addition for each VF, the VFMailbox and PFMailbox registers are defined to coordinate the transmission of the messages. These registers contain a semaphore mechanism to enable coordination of the mailbox usage.

The PF driver can decide which VFs are allowed to interrupt the PF to indicate a mailbox message using the PFMBIMR mask register.

The following flows describe the usage of the mailbox:

**Table 7-67. PF-to-VF Messaging Flow**

| Step | PF Driver                                                                          | Hardware                                    | VF #n driver |
|------|------------------------------------------------------------------------------------|---------------------------------------------|--------------|
| 1    | Set PFMAILBOX[n].PFU.                                                              |                                             |              |
| 2    |                                                                                    | Set PFU bit if PFMAILBOX[n].VFU is cleared. |              |
| 3    | Read PFMAILBOX[n] and check that PFU bit was set. Otherwise wait and go to Step 1. |                                             |              |
| 4    | Write message to relevant location in VFMBMEM.                                     |                                             |              |

**Table 7-67. PF-to-VF Messaging Flow (Continued)**

| Step | PF Driver                                                    | Hardware                        | VF #n driver                   |
|------|--------------------------------------------------------------|---------------------------------|--------------------------------|
| 5    | Set the PFMAILBOX[n].STS bit and wait for ACK <sup>1</sup> . |                                 |                                |
| 6    |                                                              | Indicate an interrupt to VF #n. |                                |
| 7    |                                                              |                                 | Read the message from VFMBMEM. |
| 8    |                                                              |                                 | Set the VFMAILBOX[n].ACK bit.  |
| 9    |                                                              | Indicate an interrupt to PF.    |                                |
| 10   | Clear PFMAILBOX[n].PFU.                                      |                                 |                                |

1. The PF might implement a timeout mechanism to detect non-responsive VFs.

**Table 7-68. VF-to-PF Messaging Flow**

| Step | PF Driver                                             | Hardware                                    | VF #n Driver                                                                       |
|------|-------------------------------------------------------|---------------------------------------------|------------------------------------------------------------------------------------|
| 1    |                                                       |                                             | Set VFMAILBOX.VFU.                                                                 |
| 2    |                                                       | Set VFU bit if VFMAILBOX[n].PFU is cleared. |                                                                                    |
| 3    |                                                       |                                             | Read VFMAILBOX[n] and check that VFU bit was set. Otherwise wait and go to Step 1. |
| 4    |                                                       |                                             | Write message to relevant location in VFMBMEM.                                     |
| 5    |                                                       |                                             | Set the VFMAILBOX[n].REQ bit.                                                      |
| 6    |                                                       | Indicate an interrupt to PF.                |                                                                                    |
| 7    | Read PFMBICR to detect which VF caused the interrupt. |                                             |                                                                                    |
| 8    | Read the adequate message from VFMBMEM.               |                                             |                                                                                    |
| 9    | Set the PFMAILBOX[n].ACK bit.                         |                                             |                                                                                    |
| 10   |                                                       | Indicate an interrupt to VF #n.             |                                                                                    |
| 11   |                                                       |                                             | Clear VFMAILBOX[n].VFU.                                                            |

The content of the message is hardware independent and is determined by software.

The messages currently assumed by this specification are:

- Registration to VLAN/multicast packet/broadcast packets — A VF can request to be part of a given VLAN or to get some multicast/broadcast traffic.
- Reception of large packet — Each VF should notify the PF driver what is the largest packet size allowed in receive.
- Get global statistics — A VF can request information from the PF driver on the global statistics.
- Filter allocation request — A VF can request allocation of a filter for queuing/immediate interrupt support.
- Global interrupt indication.
- Indication of errors.

## **7.8.2.10 DMA**

### **7.8.2.10.1 RID**

Each VF is allocated a RID. Each DMA request should use the RID of the VM that requested it. See [Section 7.8.2.6](#) for details.

### **7.8.2.10.2 Sharing of the DMA Resources**

The outstanding requests and completion credits are shared between all the VFs. The tags attached to read requests are assigned the same way as in a non-virtualized setting, although in VF systems tags can be re-used for different RIDs.

### **7.8.2.10.3 TPH**

The TPH enable is common to all the devices (all PFs and VFs). Given a TPH enabled device, each VM might decide for each queue, on which type of traffic (data, headers, Tx descriptors, Rx descriptors) the TPH should be asserted and what is the CPU ID assigned to this queue.

**Note:** There are no plans to virtualize TPH in the IOH. Thus, the physical CPU ID should be used in the programming of the *CPUID* field.

## **7.8.2.11 Timers**

### **7.8.2.11.1 TCP Timer**

The TCP timer is available only to the PF. It might indicate an interrupt to the VFs via the mailbox mechanism.

### **7.8.2.11.2 IEEE 1588**

IEEE 1588 is a per-link function and thus is controlled by the PF driver. The VMs have access to the real time clock register.

### **7.8.2.11.3 Free Running Timer**

The free running timer is a PF driver resource the VMs can access. This register is read only to all VFs and is reset only by the PCI reset.

## **7.8.2.12 Power Management and Wake-Up**

Power management is a PF resource and is not supported per VF.

### 7.8.2.13 Link Control

The link is a shared resource and as such is controllable only by the PF. This includes interface settings, speed and duplex settings, flow control settings, etc. The flow control packets are sent with the station Ethernet MAC Address stored in the NVM. The watermarks of the flow control process and the time-out value are also controllable by the PF only. In a DCB environment, the parameters of the per TC flow control are also part of the PF responsibilities.

Double VLAN is a network setting and as such should be common to all VFs.

#### 7.8.2.13.1 Special Filtering Options

Pass bad packets is a debug feature. As such, pass bad packets is available only to the PF. Bad packets are passed according to the same filtering rules of the regular packets.

**Note:** Pass bad packets might cause guest operating systems to get unexpected packets. As a result, it should be used only for debug purposes of the entire system.

Receiving long packets is enabled separately per Rx queue in the RXDCTL registers. As this impacts the flow control thresholds, the PF should be made aware of the decision of all the VMs. Because of this, the setup of TSO packets is centralized by the PF and each VF might request this setting.

## 7.8.3 Packet Switching

### 7.8.3.1 Assumptions

The following assumptions are made:

- The required bandwidth for the VM-to-VM loopback traffic is low. That is, the PCIe bandwidth is not congested by the combination of the VM-to-VM and the regular incoming traffic. This case is handled but not optimized for. Unless specified otherwise, Tx and Rx packets should not be dropped or lost due to congestion caused by loopback traffic.
- If the buffer allocated for the VM-to-VM loopback traffic is full, it is acceptable to back pressure the transmit traffic of the same TC. This means that the outgoing traffic might be blocked if the loopback traffic is congested.
- The decision on local traffic is done only according to the Ethernet DA address and the VLAN tag. There is no filtering according to other parameters (IP, L4, etc.). The switch has no learning capabilities. In case of double VLAN mode, the inner VLAN is used for the switching functionality.
- The forwarding decisions are based on the receive filtering programming.
- No packet switching between TCs.
- Coexistence with TimeSync: time stamp is not sampled for any VM-to-VM loopback traffic.
- Coexistence with Double VLAN: When double VLAN is enabled by `DMATXCTL.GDV` and it is expected to transmit untagged packets by software, transmit to receive packet switching should not be enabled.

### 7.8.3.2 Pool Selection

Pool selection is described in the following sections. A packet might be forwarded to a single pool or replicated to multiple pools. Multicast and broadcast packets are cases of replication, as is mirroring.

The following capabilities determine the destination pools of each packet:

- 128 Ethernet MAC Address filters (RAH/RAL registers) for both unicast and multicast filtering. These are shared with L2 filtering. For example, the same Ethernet MAC Addresses are used to determine if a packet is received by the switch and to determine the forwarding destination. In “E-tag pool select” mode RAL registers bits [13:0] are used for E-tag filtering {GRP, E-CID\_base} and pool selection.
- 64 shared VLAN filters (PFVLVF and PFVLVFB registers) — Each VM can be made a member of each VLAN.
- Hash filtering of unicast and multicast addresses (if the direct filters previously mentioned are not sufficient).
- Forwarding of broadcast packets to multiple pools.
- Forwarding by Ethertype.
- Mirroring by pool, VLAN, or link.

Receive pool/queue allocation refer to [Section 7.1.3.2](#).

### 7.8.3.3 Rx Packets Switching

Rx packet switching is the second of three stages that determine the destination of a received packet. The three stages are defined in [Section 7.1.3](#).

As far as switching is concerned, it does not matter whether the X550’s virtual environment operates in IOV mode or in VMDq2 mode.

When operating in replication mode, broadcast and multicast packets can be forwarded to more than one pool, and is replicated to more than one Rx queue. Replication is enabled by the *Rpl\_En* bit in the PFVTCTL register.

**Note:** For the following algorithms packets with no E-tag in *PFVTCTL.POOLING\_MODE* = 01b (E-tag mode), or all packets in *PFVTCTL.POOLING\_MODE* = 00b (MAC mode) are defined as packets with no external tags.

#### 7.8.3.3.1 Replication Mode Enabled

When replication mode is enabled, each broadcast/multicast packet can go to more than one pool. Finding the pool list of any packet is provided in the following steps:

1. **Exact unicast or multicast match** — If there is a match in one of the exact filters (RAL/RAH), for unicast or multicast packets, use the MAC Pool Select Array (MPSAR[n]) bits as a candidate for the pool list. Note that MPSAR[n] must not enable more than one pool for unicast RAL/RAH filters. The compared field differs according to the filtering mode (*PFVTCTL.POOLING\_MODE*):
  - a. If *POOLING\_MODE* = 00b (MAC mode) or for packets with no external tags, the Destination MAC Address is compared to {RAH[15:0], RAL[31:0]} for all the registers for which *RAH.ADTYPE* = 0 (MAC)

- b. If *POOLING\_MODE* = 01b (E-tag mode) and the packet has an E-tag, the E-tag E-PID (as extracted from offset 47:34, starting from the Ethertype, in the tag identified by the ETAG\_ETYPE register) is compared to RAL[13:0] for all the registers for which RAH.ADTYPE = 1 (E-tag)
2. **PFVFRE** — If any bit in the PFVFRE register is cleared, clear the respective bit in the pool list.
3. **Broadcast** — If the packet is a broadcast packet with no external tag, add pools for which their PFVML2FLT.BAM bit (*Broadcast Accept Mode*) is set.
4. **Unicast hash** — If the packet is a unicast packet with no external tag, and the prior steps yielded no pools, check it against the Unicast Hash Table (*PFUTA*). If there is a match, add pools for which their PFVML2FLT.ROPE bit (*Accept Unicast Hash*) is set.
5. **Multicast hash** — If the packet is a multicast packet with no external tag and the prior steps yielded no pools, check it against the Multicast Hash Table (MTA). If there is a match, add pools for which their PFVML2FLT.ROMPE bit (*Receive Multicast Packet Enable*) is set.
6. **Multicast promiscuous** — If the packet is a multicast packet with no external tag, take the candidate list from prior steps and add pools for which their PFVML2FLT.MPE bit (*Multicast Promiscuous Enable*) is set.
7. **Unicast Promiscuous** — If the packet is a unicast packet with no external tag, take the candidate list from prior steps and add pools for which their PFVML2FLT.UPE bit (*Unicast Promiscuous Enable*) is set.
8. **VLAN groups** — This step is relevant only when VLAN filtering is enabled by the VLNCTRL.VFE bit.
  - a. Tagged packets: enable only pools in the packet's VLAN group as defined by the VLAN filters — PFVLVF[n] and their pool list — PFVLVFB[n] or pools for which the PFVML2FLT.VPE (VLAN Promiscuous Enable) is set.
  - b. Untagged packets: enable only pools with their PFVML2FLT.AUPE bit set.
  - c. If there is no match, the pool list should be empty.
- Note:** In a VLAN network, un-tagged packets are not expected. Such packets received by the switch should be dropped, unless their destination is a virtual port set to receive these packets. The setting is done through the PFVML2FLT.AUPE bit. It is assumed that VMs for which this bit is set are members of a default VLAN and thus only MAC queuing is done on these packets.
9. **Default Pool** — If the pool list is empty at this stage and the PFVTCTL.DIS\_DEF\_POOL bit is cleared, set the default pool bit in the target pool list (from PFVTCTL.DEF\_PL).
10. **Ethertype filters** — If one of the Ethertype filters (ETQF) is matched by the packet and pooling action is requested and the *Pool Enable* bit in the ETQF is set, the pool list is set to the pool pointed to by the filter.
11. **Filter Local Packets (source address pruning)** - The pruning operation depends on the filtering mode (PFVTCTL.POOLING\_MODE):
  - a. If *POOLING\_MODE* = 00b (MAC mode) or for packets with no external tag, the Source MAC Address is compared to {RAH[15:0], RAL[31:0]} for all the registers for which RAH.ADTYPE = 0 (MAC).
  - b. If *POOLING\_MODE* = 01b (E-tag mode) and the packet has an E-tag, {00,E-tag ingress-E-CID\_base} (as extracted from offset 31:20, starting from the Ethertype, in the tag identified by the ETAG\_ETYPE register) is compared to RAL[13:0] for all the registers for which RAH.ADTYPE = 1 (E-tag).

If there is a match to one of the RAL[n]/RAH[n] clear all the pools that are set in both the matching MPSAR[n] and the PFFLP from the pool list. This prunes multicast packets from getting back to the sender in VEPA mode.

12. **PFVFRE** — If any bit in the PFVFRE register is cleared, clear the respective bit in the pool list. The PFVFRE register blocks reception by a VF while the PF configures its registers.
13. **Mirroring** — Each of the four mirroring rules adds its destination pool (PFMRCTL.MP) to the pool list if the following applies:
  - a. **Pool mirroring** — PFMRCTL.VPME is set and one of the bits in the pool list matches one of the bits in the PFMRVM register.
  - b. **VLAN port mirroring** — PFMRCTL.VLME is set and the index of the VLAN of the packet in the PFVLVF table matches one of the bits in the PFMRVLAN register.
  - c. **Uplink port mirroring** — PFMRCTL.UPME is set, the pool list is not empty.
14. **PFVFRE** — If any bit in the PFVFRE register is cleared, clear the respective bit in the pool list. The PFVFRE register blocks reception by a VF while the PF configures its registers. Note that this stage appears twice to handle mirroring cases.

### 7.8.3.3.2 Replication Mode Disabled

When replication mode is disabled, software should take care of multicast and broadcast packets and check which of the VMs should get them. In this mode, the pool list of any packet always contains one pool only according to the following steps:

1. **Exact unicast or multicast match** — The compared field differs according to the filtering mode (PFVTCTL.POOLING\_MODE):
  - a. If *POOLING\_MODE* = 00b (MAC mode) or for packets with no external tags, the Destination MAC Address is compared to {RAH[15:0], RAL[31:0]} for all the registers for which RAH.ADTYPE = 0 (MAC)
  - b. If *POOLING\_MODE* = 01b (E-tag mode) and the packet has an E-tag, the E-tag E-PID (as extracted from offset 47:34, starting from the Ethertype, in the tag identified by the ETAG\_ETYPE register) is compared to RAL[13:0] for all the registers for which RAH.ADTYPE = 1 (E-tag)If the compared field matches one of the exact filters (RAL/RAH), use the MAC Pool Select Array (MPSAR[n]) bits as a candidate for the pool list. Note that MPSAR[n] must not enable more than one pool for unicast RAL/RAH filters.
2. **PFVFRE** — If any bit in the PFVFRE register is cleared, clear the respective bit in the pool list.
3. **Unicast hash** — If the packet is a unicast packet with no external tag, and the prior steps yielded no pools, check it against the Unicast Hash Table (PFUTA). If there is a match, add the pool for which their PFVML2FLT.ROPE (*Accept Unicast Hash*) bit is set. Refer to the software limitations described after [Step 8](#).
4. **VLAN groups** — This step is relevant only when VLAN filtering is enabled by the VLNCTRL.VFE bit.
  - a. Tagged packets: enable only pools in the packet's VLAN group as defined by the VLAN filters — PFVLVF[n] and their pool list — PFVLVFB[n] or pools for which the PFVML2FLT.VPE (VLAN Promiscuous Enable) is set.
  - b. Untagged packets: enable only pools with their PFVML2FLT.AUPE bit set.
  - c. If there is no match, the pool list should be empty.
5. **Default Pool** — If the pool list is empty at this stage and the PFVTCTL.DIS\_DEF\_POOL bit is cleared, set the default pool bit in the target pool list (from PFVTCTL.DEF\_PL).

6. **Multicast or Broadcast** — If the packet is a multicast or broadcast packet with no external tag and was not forwarded in [Step 1](#) and [Step 2](#), set the default pool bit in the pool list (from PFVCTL.DEF\_PL).
7. **Ethertype filters** — If one of the Ethertype filters (ETQF) is matched by the packet and queuing action is requested and the *Pool Enable* bit in the ETQF is set, the pool list is set to the pool pointed by the filter.
8. **PFVFRE** — If any bit in the PFVFRE register is cleared, clear the respective bit in the pool list. The PFVFRE register blocks reception by a VF while the PF configures its registers.

The following software limitations apply when replication is disabled:

- Software must not set more than one bit in the bitmaps of the exact filters. Note that multiple bits can be set in an RAH register as long as it's guaranteed that the packet is sent to only one queue by other means (such as VLAN).
- Software must not set per-VM promiscuous bits (multicast or broadcast).
- Software must not set the *ROPE* bit in more than one PFVML2FLT register.
- Software should not activate mirroring.
- Software should not filter out local packets by setting PFFLP bits

#### 7.8.3.4 Tx Packets Switching

Tx switching is used only in a virtualized environment to serve VM-to-VM traffic. Packets that are destined to one or more local VMs are directed back (loopback) to the Rx packet buffers. Enabling Tx switching is done by setting the PFDTXGSWC.LBE bit. Tx to Rx switching always avoids packet drop as if flow control is enabled. Therefore, the software must set the FCRTTH[n].RTH fields regardless if flow control is activated on the X550.

Tx switching rules are very similar to Rx switching in a virtualized environment, with the following exceptions:

- If a target pool is not found, the default pool is used only for broadcast and multicast packets.
- A unicast packet that matches an exact filter is not sent to the LAN.
- Broadcast and multicast packets are always sent to the external LAN.
- A packet might not be sent back to the originating pool (even if the destination address is equal to the source address) unless loopback is enabled for that pool by the PFVMTXSW[n] register.

The detailed flow for pool selection as well as the rules that apply to loopback traffic is as follows:

- Loopback is disabled when the network link is disconnected. It is expected (but not required) that system software (including VMs) does not post packets for transmission when the link is disconnected.
- Loopback is disabled when the *RXEN (Receive Enable)* bit is cleared.
- Loopback packets are identified by the *LB* bit in the receive descriptor.

**Notes:** When Tx switching is enabled, the host must avoid sending packets longer than 9.5 KB.

Tx Switching should be enabled only if PFVCTL.POOLING\_MODE = 00b (MAC mode).

### 7.8.3.4.1 Replication Mode Enabled

When replication mode is enabled, the pool list for any packet is determined according to the following steps:

1. **Exact unicast or multicast match** — If there is a match in one of the exact filters (RAL/RAH), for unicast or multicast packets, take the MPSAR[n] bits as a candidate for the pool list. Note that MPSAR[n] must not enable more than one pool for unicast RAL/RAH filters.
2. **Ether-type filters** — If one of the enabled (ETQF.TX\_ANTISPOOF) Transmit Ether-type filters (ETQF.ETYPE) is matched by the packet and the appropriate Pool loopback/anti-spoof bit in the PFVFSPOOF is set (PFVFSPOOF.ETHERTYPELB/PFVFSPOOF.ETHERTYPEAS), the pool list is set to the pool pointed to by the ETQS matching register (loopback) or the packet is dropped (anti-spoof). All the subsequent steps after [Step 3](#) are skipped.
 

**Note:** Loopback on ETQF match is possible even if the general loopback enable bit (PFDTXGSWC.LBE) is clear.
3. **PFVFRE** — If any bit in the PFVFRE register is cleared, clear the respective bit in the pool list.
4. **Broadcast** — If the packet is a broadcast packet, add pools for which their PFVML2FLT.BAM bit (*Broadcast Accept Mode*) is set.
5. **Unicast hash** — If the packet is a unicast packet, and the prior steps yielded no pools, check it against the Unicast Hash Table (PFUTA). If there is a match, add pools for which their PFVML2FLT.ROPE bit (*Accept Unicast Hash*) is set.
6. **Multicast hash** — If the packet is a multicast packet and the prior steps yielded no pools, check it against the Multicast Hash Table (MTA). If there is a match, add pools for which their PFVML2FLT.ROMPE bit (*Receive Multicast Packet Enable*) is set.
7. **Unicast Promiscuous** - If the packet is a unicast packet, take the candidate list from prior steps and add pools for which their PFVML2FLT.UPE bit (*Unicast Promiscuous Enable*) is set.
8. **Multicast Promiscuous** — If the packet is a multicast packet, take the candidate list from prior steps and add pools for which their PFVML2FLT.MPE bit (*Multicast Promiscuous Enable*) is set.
9. **Filter source pool** — The pool from which the packet was sent is removed from the pool list unless the PFVMTXSW.LLE bit is set.
10. **VLAN groups** — This step is relevant only when VLAN filtering is enabled by the VLNCTRL.VFE bit.
  - a. Tagged packets: enable only pools in the packet's VLAN group as defined by the VLAN filters — PFVLVF[n] and their pool list — PFVLVFB[n] or pools for which the PFVML2FLT.VPE (*VLAN Promiscuous Enable*) is set.
  - b. Untagged packets: enable only pools with their PFVML2FLT.AUPE bit set.
  - c. If there is no match, the pool list should be empty.
11. **Forwarding to the network** — Packets are forwarded to the network in the following cases:
  - a. All broadcast and multicast packets.
  - b. Unicast packets that do not match any exact filter. A match of an exact filter that also points to a pool disabled via PFVFRE is not considered a match.
12. **PFVFRE** — If any bit in the PFVFRE register is cleared, clear the respective bit in the pool list (pre mirroring step).

13. **Mirroring** — Each of the following three mirroring rules adds its destination pool (PFMRCTL.MP) to the pool list if the following applies:
  - a. **Pool mirroring** — PFMRCTL.VPME is set and one of the bits in the pool list matches one of the bits in the PFMRVM register.
  - b. **VLAN port mirroring** — PFMRCTL.VLME is set and the index of the VLAN of the packet in the PFVLVF table matches one of the bits in the PFMRVLAN register.
  - c. **Downlink port mirroring** — PFMRCTL.DPME is set and the packet is sent to the network.
14. **PFVFRE** — If any bit in the PFVFRE register is cleared, clear the respective bit in the pool list (post mirroring step).

#### 7.8.3.4.2 Replication Mode Disabled

When replication mode is disabled, software should take care of multicast and broadcast packets and check which of the VMs should get them. In this mode the pool list for any packet always contains one pool only according to the following steps:

1. **Exact unicast or multicast match** — If the packet DA matches one of the exact filters (RAL/RAH), take the MPSAR[n] bits as a candidate for the pool list. Note that MPSAR[n] must not enable more than one pool for unicast RAL/RAH filters.
2. **Ether-type filters** - if one of the enabled (ETQF.TX\_ANTISPOOF) Transmit Ether-type filters (ETQF.ETYPE) is matched by the packet and the appropriate Poll loopback/anti-spoof bit in the PFVFSPOOF is set (PFVFSPOOF.ETHERTYPELB/PFVFSPOOF.ETHERTYPEAS), the pool list is set to the pool pointed to by the ETQS matching register (loopback) or the packet is dropped (anti-spoof). All the subsequent steps after [Step 3](#) are skipped.

**Note:** Loopback on Ethertype match is possible even if the general loopback enable bit (PFDTXGSWC.LBE) is clear.

3. **PFVFRE** — If any bit in the PFVFRE register is cleared, clear the respective bit in the pool list.
4. **Unicast hash** — If the packet is a unicast packet, and the prior steps yielded no pools, check it against the Unicast Hash Table (PFUTA). If there is a match, add the pool for which their PFVML2FLT.ROPE bit (*Accept Unicast Hash*) is set. Refer to the software limitations that follow.
5. **VLAN groups** — This step is relevant only when VLAN filtering is enabled by the VLNCTRL.VFE bit.
  - a. Tagged packets: enable only pools in the packet's VLAN group as defined by the VLAN filters — PFVLVF[n] and their pool list — PFVLVFB[n] or pools for which the PFVML2FLT.VPE (*VLAN Promiscuous Enable*) is set.
  - b. Untagged packets: enable only pools with their PFVML2FLT.AUPE bit set.
  - c. If there is no match, the pool list should be empty.
6. **Multicast or Broadcast** — If the packet is a multicast or broadcast packet and was not forwarded in [Step 1](#) and [Step 2](#), set the default pool bit in the pool list (from PFVTCTL.DEF\_PL).
7. **Filter source pool** — The pool from which the packet was sent is removed from the pool list unless the PFVMTXSW.LLE bit is set.
8. **Forwarding to the Network** — Packets are forwarded to the network in the following cases:
  - a. All broadcast and multicast packets.
  - b. Unicast packets that do not match any exact filter. A match of an exact filter that also points to a pool disabled via PFVFRE is not considered a match.
9. **PFVFRE** — If any bit in the PFVFRE register is cleared, clear the respective bit in the pool list.

The following software limitations apply when replication is disabled:

1. It is software's responsibility not to set more than one bit in the bitmaps of the exact filters. Note that multiple bits can be set in an RAH register as long as it is guaranteed that the packet is sent to only one queue by other means (such as VLAN)
2. Software must not set per-VM promiscuous bits (multicast or broadcast).
3. Software must not set the *ROPE* bit in more than one PFVML2FLT register.
4. Software should not activate mirroring.

### 7.8.3.5 Mirroring Support

The X550 supports four separate mirroring rules, each associated with a destination pool (mirroring can be done in up to four pools). Each rule is programmed with one of the four mirroring types:

- **Pool Mirroring** — Reflects all the packets received to a pool from the network.
- **Uplink Port Mirroring** — Reflects all the traffic received from the network that reached any pool.
- **Downlink Port Mirroring** — Reflects all the traffic transmitted to the network.
- **VLAN Mirroring** — Reflects all the traffic received from the network in a set of given VLANs (either from the network or from local VMs).

**Note:** Reflecting all the traffic received by any of the pools (either from the network or from local VMs) is supported by enabling mirroring of all pools.

**Note:** To get all traffic irrespective of the filtering rules, the mirroring pool should be set to promiscuous mode and promiscuous VLAN mode.

**Note:** Mirroring and replication on FCoE traffic is not supported on receive if the ETQF filters define FCoE packets and on transmit if the packets are indicated as FCoE (by setting the *FCoE* bit in the *TUCMD* field in the Transmit Context Descriptor).

Mirroring modes are controlled by a set of rule control registers:

- **PFMRCTL** — Controls the rules to be applied and the destination port.
- **PFMRVLAN** — Controls the VLAN ports as listed in the PFVLVF table taking part in the VLAN mirror rule.
- **PFMRVM** — Controls the pools taking part in the pool mirror rule.

### 7.8.3.6 Offloads

The general rule is that offloads are executed as configured for the pool and queue associated with the receive packet. Some special cases:

- If a packet is directed to a single pool, offloads are determined by the pool and queue for that packet.
- If a packet is replicated to more than one pool, each copy of the packet is offloaded according to the configuration of its pool and queue.
- If replication is disabled, offloads are determined by the unique destination of the packet.

The following subsections describe exceptions to the previously described special cases.

### 7.8.3.6.1 Local Traffic Offload

The following capabilities are not supported on the loopback path:

- The RSS and VLAN strip offload capabilities are only supported if the *CC* bit in the transmit descriptor of the packet is set and if it is a tunnel packet, the *TUNNEL. OUTERIPCS* is set also. The reason is that when these bits are not set, software does not provide the necessary offload offsets with the Tx packet.
- Receive Side Coalescing (RSC) is not supported.
- FCoE offloads are not supported.

### 7.8.3.6.2 Rx Traffic Offload

- CRC offload is a global policy. CRC strip is enabled or disabled for all received packets.

## 7.8.3.7 Rate Control Features

### 7.8.3.7.1 Congestion Control

Tx packets going through the local switch are stored in the Rx packet buffer, similar to packets received from the network. Tx to Rx switching always avoids packet drop as if flow control is enabled. Therefore, the software must set the *FCRTH[n].RTH* fields regardless if flow control is activated on the X550.

The X550 guarantees that one TC flow is not affected by congestion in another TC.

Receive and local traffic are provided with the same priority and performance expectations. Packets from the two sources are merged in the Rx packet buffers, which can in general support both streams at full bandwidth. Any congestion further in the pipeline (such as lack of PCIe bandwidth) evenly affects Rx and local traffic.

### 7.8.3.7.2 Tx Queue Arbitration and Rate Control

To guarantee each pool with adequate bandwidth, a per-pool bandwidth control mechanism is added to the X550. Each Tx pool gets a percentage of the transmit bandwidth and is guaranteed it can transmit within its allocation. This arbitration is combined with the TC arbitration. See additional details on DCB Tx capabilities in [Section 7.6.2.1](#).

### 7.8.3.7.3 Receive Priority

As the switch might decide to loopback packets from the transmit path to the receive path, in case the receive path is full, the transmit path might be blocked (including the traffic to the LAN). The X550 guarantees that packets are not dropped because of that and that one traffic class flow is not affected by congestion in another traffic class. The PF driver might decide to program the X550 to drop packets from receive queues without available descriptors.

To keep the congestion effect locality, receive traffic from the LAN have higher priority than loop back traffic. This way large loopback traffic does not impact the network.

### 7.8.3.8 Small Packets Padding

In Virtualized systems, the driver receiving the packet in the VM might not be aware of all the hardware offloads applied to the packet. Thus, in case of stripping actions by the hardware (VLAN strip), it might receive packets which are smaller than a legal packet. The X550 provides an option to pad small packets in such cases so that all packets have a legal size. This option can be enabled only if the CRC is stripped. In these cases, all small packets are padded to 60 bytes (legal packet - 4 bytes CRC). The padding is done with zero data. This function is enabled via the `RDRXCTL.PSP` bit.

Packet padding is done after tag extractions and do not take into account if tags are exposed in the Rx descriptor status.

**Notes:** FCoE DDP packets are not padded.

The packet length reported in the descriptor reflects the packet length before padding.

If a timestamp is added, it is part of the padding data.

### 7.8.3.9 Switch Control

The PF driver has some control of the switch logic. The following registers are available to the PF for this purpose:

- **PFVTCTL (PF Virtual Control Register)**

- **RPL\_EN (Replication Enable)** — Enables replication of multicast and broadcast packets — both in incoming and local traffic. If this bit is cleared, Tx multicast and broadcast packets are sent only to the network and Rx multicast and broadcast packets are sent to the default pool.
- **DEF\_PL (Default Pool)** — Defines the target pool for packets that passed L2 filtering but did not pass any of the pool filters. This field is invalid when the `DIS_DEF_POOL` bit is set.
- **DIS\_DEF\_POOL (Disable Default Pool)** — Disables acceptance of packets that failed all pool filters.

- **PFVFRE (PF VF Receive Enable)** — Enables/disables reception of packets from the link to a specific VF. Used during initialization of the VF. See [Section 4.2.2.2](#) for more details.

- **PFDTXGSWC (PF DMA Tx General Switch Control)**

- **LBE (Loopback Enable)** — VMDQ loopback enables switching of Tx traffic to the Rx path for VM-to-VM communication.

- **PFVFSPOOF (PFVF Anti-Spoof Control)**

- **MACAS (MAC Anti-Spoof Enable)** — Enables filtering of Tx packet for anti-spoof.

- **PFVMTXSW (PF VM Tx Switch Loopback Enable)**

- **LLE (Local Loopback Enable)** — Local Loopback Enable defines whether to allow loopback of a packet from a certain pool into itself.

- **PFQDE (PF Queue Drop Enable Register)** — A register defining global policy for drop enable functionality when no descriptors are available. It lets the PF override the per-queue `SRCTL[n].DROP_EN` setting. PFQDE should be used in SR-IOV mode as described in [Section 4.6.11.3.1](#).

- **PFVML2FLT (PF VM L2Control Register)**

- **ROMPE (Receive Overflow Multicast Packets)** — Accept multicast hash. Defines whether a pool accepts packets that match the multicast MTA table.

- **ROPE (Receive MAC Filters Overflow)** — Accept unicast hash. Defines whether a pool accepts packets that match the unicast PFUTA table.
- **BAM (Broadcast Accept)** — Defines whether a pool accepts broadcast packets.
- **MPE (Multicast Promiscuous Enable)** — Defines whether or pool accepts all multicast packets.
- **AUPE (Accept Untagged Packets Enable)** — Defines whether a pool accepts untagged VLAN packets.
- **Mirror Control** — See [Section 7.8.3.5](#).
- **PFVFTE (PF VF Transmit Enable)** — Enables/disables transmission of packets to the link to a specific VF. Used during initialization of the VF. See [Section 4.2.2.2](#) for more details.
- **PFVLVF/PFVLVFB (PF VM VLAN Pool Filter/Bitmap)** — VLAN queuing table. A set of 64 VLAN entries with an associated bitmap, one bit per pool. Bits are set for each pool that participates in this VLAN.
- **PFUTA (PF Unicast Table Array)** — A 4 Kb array that covers all combinations of 12 bits from the MAC destination address. A received unicast packet that misses the MAC filters is compared against the PFUTA. If the relevant bit in the PFUTA is set, the packet is routed to all pools for which the *ROPE* bit is set.
- **MTA (Multicast Table Array)** — A 4 Kb array that covers all combinations of 12 bits from the MAC destination address. A received multicast packet that misses the MAC filters is compared against the MTA. If the relevant bit in the MTA is set, the packet is routed to all pools for which the *ROMPE* bit is set.

In addition, the rate-control mechanism is programmed as described in [Section 7.6.2.1](#).

## 7.8.4 Security Features

The X550 allows some security checks on the inbound and outbound traffic of the switch.

### 7.8.4.1 Inbound Security

Each incoming packet (either from the LAN or from a local VM) is filtered according to the VLAN tag so that packets from one VLAN cannot be received by pools that are not members of that VLAN.

### 7.8.4.2 Outbound Security

#### 7.8.4.2.1 MAC Anti-Spoofing

Each pool is associated with one or more Ethernet MAC Addresses on the receive path. The association is determined through the MPSAR registers. The MAC anti-spoofing capability insures that a VM always uses a source Ethernet MAC Address on the transmit path that is part of the set of Ethernet MAC Addresses defined on the Rx path. A packet with a non-matching SA is dropped, preventing spoofing of the Ethernet MAC Address. This feature is enabled in the *PFVFSPOOF.MACAS* field, and can be enabled per Tx pool.

**Note:** Anti-spoofing is not available for VMs that hide behind other VMs whose Ethernet MAC Addresses are not part of the RAH/RAL Ethernet MAC Address registers. In this case, anti-spoofing should be done by software switching, handling these VMs.

#### 7.8.4.2.2 VLAN Anti-Spoofing

Each pool is associated with one or more VLAN tags on the receive path. The association is determined through the PFVLVF and PFVLVFB registers. The VLAN anti-spoofing capability insures that a VM always uses a VLAN tag on the transmit path that is part of the set of VLAN tags defined on the Rx path. A packet with a non-matching VLAN tag is dropped, preventing spoofing of the VLAN tag. This feature is enabled in the PFVFSPOOF.VLANAS field, and can be enabled per Tx pool.

**Notes:** If VLAN anti-spoofing is enabled, MAC anti-spoofing must be enabled as well.

When double VLAN is enabled by DMATXCTL.GDV and it is expected to transmit untagged packets by software, VLAN anti-spoofing should not be enabled.

Un-tagged packets are not checked by VLAN anti-spoofing.

#### 7.8.4.2.3 VLAN Tag Validation

In PCI-SIG IOV scenarios the driver might be malicious, and thus might fake a VLAN tag. The X550 provides the ability to force a specific VLAN value for a VM. The possible behaviors are controlled by the PFVMVIR[n] registers as follows:

- **Use descriptor value** — To be used in case of a trusted VM that can decide which VLAN to send. This option should also be used in case one VM is member of multiple VLANs.
- **Always insert default VLAN** — This mode should be used for non-trusted or non-VLAN aware VMs. In this case, any VLAN insertion command from the VM is ignored. If a packet is received with a VLAN, the packet should be dropped.
- **Never insert VLAN** — This mode should be used in a non-VLAN network. In this case, any VLAN insertion command from the VM is ignored. If a packet is received with a VLAN, the packet should be dropped.

**Notes:** The VLAN insertion settings should be done before any of the queues of the VM are enabled.

When double VLAN is enabled by DMATXCTL.GDV and it is expected to transmit untagged packets by software, VLAN validation should not be enabled.

#### 7.8.4.2.4 E-tag Insertion

In addition to the VLAN insertion described above, the device can add an E-tag to the packets sent by a VF. The PFVMVIR[n].TAGA bit defines if a tag should be added. If this bit is set, the added tag is as follows:

- TAGA = 00b (MAC mode) or 11b (Reserved): Insert no tag.
- TAGA = 01b (E-tag mode): An E-tag is added as follows:  
`{TAG_ETYPE.ETAG_ETHERTYPE[15:0], PFVMTIR.PORT_TAG_ID[31:0], 0x0000}`.

**Notes:** The E-tag insertion settings should be done before any of the queues of the VM are enabled.

#### 7.8.4.2.5 Ether-type Anti-Spoofing/Pruning

Each pool can be set to drop packets associated with one or more (up to 8) Ether-types on the transmit path. The Ether-types are defined using the ETQF registers. The Ether-type pruning (anti-spoof) capability ensures that a VM does not send out LLDP/ECP control frames to external switches. The Ether-type loopback capability enables the loopback of link layer packets to a pre defined pool destination.

Ether-type pruning (anti-spoof) feature is enabled in the `PFVFSPOOF.ETHERTYPEAS` field, and can be enabled per transmit pool. Ether-type loopback feature is enabled in the `PFVFSPOOF.ETHERTYPELB` field, and can be enabled per transmit pool.

### 7.8.4.3 Malicious Driver Detection

The hardware can be programmed to take some action as a result of some misbehavior of a VM. These actions might hint to the fact that some VM is malicious and the VMM should remedy the situation. To inform the VMM of this fact, The Mailbox bit (`EICR.MAILBOX` bit) may be set to indicate the occurrence of such behavior. The `LMVM_RX` and `LMVM_TX` register contains information on which queue (`LMVM_TX.LAST_Q` or `LMVM_RX.LAST_Q`) and port (`LMVM_TX.MAL_PF` and `LMVM_RX.MAL_PF`) the malicious behavior was detected. The `LVMMC_TX` and `LVMMC_RX` registers contain information on the type of error detected and are clear by read.

Malicious driver behavior detection is enabled by setting the `DMATXCTL.MDP_EN` and `RDRXCTL.MDP_EN` bits to 1. This capability should be enabled before queues are exposed to non trusted virtual machines.

On detection of a malicious driver event the X550 stops activity of the offending queue, and sets the bit matching the offending queue in `WQBR_RX` and `WQBR_TX` registers. If `DMATXCTL.MBINTEN` or `RDRXCTL.MBINTEN` are set, the X550 generates an interrupt for transmit or receive errors respectively by asserting the `EICR.MAILBOX` bit. Cause of Malicious driver activation is reported in the `LVMMC_TX` and `LVMMC_RX` registers. To re-activate offending queue, driver should release it by setting the matching bit in `WQBR_RX` or `WQBR_TX` register.

The `WQBR_RX` and `WQBR_TX` registers keeps track of all the queues on which a malicious activity was detected and can be used by the driver to track multiple events.

After the queue is disabled the initialization flow defined in [Section 4.6.7.1](#) for receive queues and in [Section 4.6.8.1](#) for transmit queues should be applied.

#### 7.8.4.3.1 Queue Context Validation

The X550 checks that the queue context submitted when a queue is enabled is valid. It also prevents change to static configuration while the queue is enabled. These checks are done both for receive and transmit queues. The table below describes the checks done on the queue context:

| Check type                               | Description                                                                                                                                                                                                                                                | Bit in LVMMC_TX/RX  | Action                  |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|-------------------------|
| Receive queue context validity           | Check that: <ul style="list-style-type: none"> <li>RDLEN &gt; 0</li> <li>SRRCTL.BSIZEPACKET &gt; 0</li> <li>SRRCTL.BSIZEHEADER &gt; 0 if DESCTYP requires header split</li> <li>SRRCTL.BSIZEHEADER &lt;= 1024</li> <li>SRRCTL.DESCTYPE is valid</li> </ul> | INVALID_RXQ_CONTEXT | Prevent Enable of queue |
| Receive queue context change on the fly  | Attempt to write RDBAL, RDBAH, RDLEN, or SRRCTL while queue is enabled                                                                                                                                                                                     |                     | Disable queue.          |
| Transmit queue context validity          | Check that: <ul style="list-style-type: none"> <li>TDLEN &gt; 0</li> </ul>                                                                                                                                                                                 | INVALID_TXQ_CONTEXT | Prevent Enable of queue |
| Transmit queue context change on the fly | Attempt to write TDBAL, TDBAH, TDLEN, TDWBAL, or TDWBAH while queue is enabled                                                                                                                                                                             |                     | Disable queue.          |

**Note:** Queue zero is enabled by default. Thus, if malicious driver protection is enabled, to change Queue zero configuration, the queue should be disabled.

### 7.8.4.3.2 Transmit Descriptor Validity Checks

The table below describes the checks are done by the X550 to define if a transmit packet descriptor is valid. All the checks are done on the descriptors. The checks on the packet header are described in the previous sections.

**Table 7-69. Malicious Driver - TX Descriptor Checks**

| Check type                                  | Description                                                                                                                   | Bit in LVMMC_TX   | Action                                 |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|-------------------|----------------------------------------|
| Mac Header size                             | Checks that the MAC header size in the context descriptor is at least 14 (or 18 in case of offloaded packet and double VLAN). | MAC_HEADER        | Drop Packet and stop offending queue   |
| IPv4 Header                                 | If a checksum or TSO offload is required, checks that the IPv4 header size in the context descriptor is at least 20.          | IPv4_HEADER       | Drop Packet and stop offending queue   |
| IPv6 Header                                 | If a TSO offload is required, checks that the IPv6 header size in the context descriptor is at least 40.                      | IPv6_HEADER       | Drop Packet and stop offending queue   |
| Wrong MAC_IP                                | Check that the MAC+ IP (+ OUTERIP + TUNNEL) header size is not bigger than the packet size.                                   | WRONG_MAC_IP      | Drop Packet and stop offending queue   |
| TCP header size                             | If a TCP TSO offload is required, checks that the TCP header size in the context descriptor is at least 20.                   | TCP_LSO           | Drop Packet and stop offending queue   |
| UDP header size                             | If a UDP TSO offload is required, checks that the TCP header size in the context descriptor is at least 8.                    | UDP_LSO           | Drop Packet and stop offending queue   |
| SCTP data size                              | If a SCTP checksum offload is required, checks that the SCTP L4 packet size (including header and data) is at least 12.       | STCP_CS           | Drop Packet and stop offending queue   |
| Packet too big                              | In case of a single send, check that the packet is not larger than 15.5KBytes.                                                | SIZE              | Drop Packet and stop offending queue   |
| Packet too small                            | Check that the total length of the packet transmitted, not including FCS is at least 13 bytes.                                | N/A               | Silently drop packet.                  |
| Illegal offload request.                    | Check that TSO is no requested for SCTP or that a checksum offload is not requested for IPv6 packets.                         | OFF_ILL           | Drop Packet and stop offending queue   |
| Illegal IPsec offload request by VF         | Check that a VF had not requested IPsec offload                                                                               | IPSEC_OFFLOAD     | Drop Packet and stop offending queue   |
| Illegal FCoE offload request by VF          | Check that a VF had not requested FCoE offload                                                                                | FCOE_OFFLOAD      | Drop Packet and stop offending queue   |
| SCTP alignment                              | If an SCTP CRC offload is requested, check that the data size is 4 byte aligned.                                              | SCTP_ALIGNED      | Drop Packet and stop offending queue   |
| Zero MSS                                    | Check that the MSS size is larger than zero.                                                                                  | ZERO_MSS          | Drop Packet and stop offending queue   |
| Context in middle of packet                 | Check that a context descriptor is not sent in the middle of a packet.                                                        | CONTEXT_IN_PACKET | Drop Packet and stop offending queue   |
| Number of large send header buffers         | Check that the Large send header is contained in at most 4 buffers.                                                           | LSO_MORE_THAN_4   | Drop Packet and stop offending queue   |
| Buffers size and length match - Single Send | For single send, check that the total of all buffers size and the packet length match.                                        | OOS_SSO           | Drop Packet and stop offending queue   |
| Buffers size and length match - Large Send  | For LSO, check that the total of all buffers size and the packet length match.                                                | OOS_LSO           | Drop Packet and stop offending queue   |
| LSO wrong header size                       | For LSO, check that the size of the header fetched actually match the expected header size.                                   | N/A               | Silently drop packet. Counted in SSVPC |
| UDP data size                               | If a UDP checksum offload is required, checks that the UDP L4 packet size in the context descriptor is at least 8.            | SSO_UDP           | Drop Packet and stop offending queue   |

**Table 7-69. Malicious Driver - TX Descriptor Checks (Continued)**

| Check type                  | Description                                                                                                         | Bit in LVMMC_TX | Action                               |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------|-----------------|--------------------------------------|
| TCP data size               | If a TCP checksum offload is required, checks that the TCP L4 packet size in the context descriptor is at least 20. | SSO_TCP         | Drop Packet and stop offending queue |
| Descriptor Type             | Check that only descriptor types 2 (context) or 3 (advanced data descriptor) are used.                              | DESC_TYPE       | Drop Packet and stop offending queue |
| CC bit not set when needed  | CC (Check Context) bit in descriptor is not set in virtualization mode.                                             |                 | Drop Packet and stop offending queue |
| Null packet check           | Check that a Null packet has the EOP bit set.                                                                       | WRONG_NULL      | Drop Packet and stop offending queue |
| Packet without EOP          | Check that a only entire packets are provided by the driver                                                         | NO_EOP          | Drop Packet and stop offending queue |
| Burst of contexts           | Check that less than 4 Contiguous context descriptor are sent by the driver.                                        | CONTEXT_BURST   | Drop Packet and stop offending queue |
| Legacy Descriptor in SR-IOV | Legacy descriptor used when SR-IOV is enabled.                                                                      | LEGACY_DESC_IOV | Drop Packet and stop offending queue |

### 7.8.4.3.3 Reactive Malicious Behavior Detection

The table below describes the checks are done by the X550 to detect a malicious behavior, even if the packet seems valid.

**Table 7-70. Reactive Malicious Checks**

| Check type                                       | Description                                                                                                                                    | Bit in LVMMC_TX/RX | Action                                                                |
|--------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|-----------------------------------------------------------------------|
| Malicious VF memory access                       | A PCIe DMA access initiated by a VF ended with Unsupported Request (UR) or Completer Abort (CA). This check is done for both Tx and Rx queues. | INV_MACC           | Drop Packet and stop offending queue                                  |
| DMA access outside of active memory <sup>1</sup> | A Queue attempt to read memory outside of the active memory range of the system. See <a href="#">Section 3.1.5.7</a> for details.              | INV_MACC           | Drop PCIe read transaction. Stop queue that requested the transaction |
|                                                  | A Queue attempt to write memory outside of the active memory range of the system. See <a href="#">Section 3.1.5.7</a> for details.             | N/A                | Silently drop PCIe write transaction.                                 |
| VLAN not expected in packet                      | A packet where VLAN should be added by device is in Tx descriptor. See <a href="#">Section 7.8.4.2.3</a>                                       | VLAN_IERR          | Drop Packet                                                           |
| Anti-spoof checks                                | See <a href="#">Section 7.8.4.2.1</a> and <a href="#">Section 7.8.4.2.2</a> and <a href="#">Section 7.8.4.2.5</a> for details                  | MAC_VLAN_SPOOF     | Drop Packets.                                                         |

1. A PCIe error interrupt can be asserted when such a transaction is dropped. See [Section 3.1.5](#) for details.

## 7.8.5 Virtualization of Hardware

This section describes additional features used in both IOV and VMDq2 modes.

### 7.8.5.1 Per-Pool Statistics

Part of the statistics are by definition shared and cannot be allocated to a specific VM. For example, CRC error count cannot be allocated to a specific VM, as the destination of such a packet is not known if the CRC is wrong.

All the non-specific statistics are handled by the PF driver in the same way it is done in non-virtualized systems. A VM might request a statistic from the PF driver but might not access it directly.

The conceptual model used to gather statistics in a virtualization context is that each queue pool is considered as a virtual link and the Ethernet link is considered as the uplink of the switch. Thus, any packet sent by a pool is counted in the Tx statistics, even if it was forwarded to another pool internally or was dropped by the MAC for some reason. In the same way, a replicated packet is counted in each of the pools receiving it.

The following statistics are provided per pool:

- Good packet received count
- Good packet transmitted count
- Good octets received count
- Good octets transmitted count
- Multicast packets received count

**Note:** All the per VF statistics are read only and wrap around after reaching their maximum value.

## 7.9 Tunneling Support

The X550 supports the VXLAN and NVGRE tunneling packet formats. As part of this support the following features are supported:

- LSO and transmit checksum offloads for tunneled packets as described in [Section 7.2.4](#) and [Section 7.2.5](#).
- RSS forwarding based on inner L3/L4 header as described in [Section 7.1.3.7](#)
- Flow director forwarding based on Tenant ID, inner MAC and inner VLAN as described in [Section 7.1.3.6](#)
- New indications in the receive descriptor with information on the tunnel headers and on the outer header checksum as described in [Section 7.1.5.2](#)
- New packet split modes based on the tunnel header or outer L2 header as described in [Section A.2.5](#)

## 7.10 Receive Side Coalescing (RSC)

The X550 can merge multiple received frames from the same TCP/IP connection (referred to as flow in this section) into a single structure. The X550 does this by coalescing the incoming frames into a single or multiple buffers (descriptors) that share a single accumulated header. This feature is called RSC. Note that the term Large Receive is used to describe a packet construct generated by RSC.

The X550 digests received packets and categorizes them by their TCP/IP connections (flows). For each flow, hardware coalesces the packets as shown in Figure 7-41 and Figure 7-42 (the colored parameters are explained in the RSC context table and receive descriptor sections). The X550 can handle up to 32 concurrent flows per LAN port at any given time. Each flow handled by RSC offload has an associated context. The X550 opens and closes the RSC contexts autonomously with no need for any software intervention. Software needs only to enable RSC in the selected receive queues.

**Note:** When RSC is enabled, advanced receive descriptors should be used and CRC strip should be enabled.

Figure 7-41 shows a top level flow diagram that is used for RSC functionality. The following sections provide a detailed explanation of this flow as well as the memory structures and device settings that support the RSC functionality.

**Figure 7-41. RSC Functionality (No Header Split)**

**Figure 7-42. RSC Functionality (No Header Split)**

**Note:** Software might abort reception to any queue at any time. For example: VFLR or queue disable. Following these settings, hardware aborts further DMA(s) and descriptor completions. Specifically, active RSC(s) in the specific queue(s) are not completed. In such cases there could be completed packets and RSC(s) hidden from software by prior incomplete RSC(s).

**Figure 7-43. RSC Event Flow**

## 7.10.1 Packet Candidacy for RSC

Incoming packets can be good candidates for RSC offload when the following conditions are met. If any of the these conditions are not met, and assuming the queue is configured as required in [Section 4.6.7.2](#) the received packet is processed in the legacy (non-coalescing) scheme.

- RSC is enabled in the destination receive queue by the `RSCCTL.RSCEN`. In this case, software must set the `SRRCTL.DESCTYPE` field in the relevant queues to advanced descriptor modes.
- RSC is further enabled by the `RSCINT.RSCEN` for the receive queues associated to the interrupts defined by the `RSCINT` registers.
- The `SRRCTL[n].BSIZEHEADER` (header buffer size) must be larger than the packet header (even if header split is not enabled). A minimum size of 128 bytes for the header buffer addresses this requirement.
- The received packet has no MAC errors and no TCP/IP checksum errors. MAC errors are:
  - CRC error.
  - Undersize frame received.
  - Oversize frame received.
  - Error control byte received in mid-packet.
  - Illegal code byte received in mid-packet.
- If the *Length* field in the IP header does not cover the entire packet (as the case for padding bytes), the received packet is not a candidate for RSC.
- The packet type is TCP/IPv4 (non-SNAP) with optional VLAN header(s). RSC is not supported for IPv6 packets.
- The packet is not an NVGRE or VXLAN packet.
- IP header does not carry any option headers.
- See [Section 4.6.7.2](#) for the required configuration to enable or disable NFS coalescing.
- The TCP segment is not fragmented.
- The following TCP flags are inactive: FIN, SYN, RST, URG, ECE, CWR, NS and the other three reserved TCP flags (see TCP Flags mapping in [Table 7-72](#)).
- The *ECT* and *CE* bits in the *TOS* field in the IP header are not equal to 11b (see the flags in [Table 7-73](#)).
- Packets with PSH TCP flag are coalesced but also close the large receive.
- The packet does not carry any TCP option headers.
- RSC is not supported for a switched packet transmitted from a local VM.
- When a Rx packet is replicated or mirrored, it can be coalesced only on the Rx queue that belongs to the source VM.
- Note that there are no limitations on the maximum packet length including jumbo packets.
- If there is already an active RSC for the matched flow, a few additional conditions should be met as listed in [Section 7.10.4](#).

The supported packet format is as follows:

**Table 7-71. Packet Fields**

| Size            | Packet Fields                                                                                                                            |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------|
| 6 bytes         | Destination Ethernet MAC Address.                                                                                                        |
| 6 bytes         | Source Ethernet MAC Address.                                                                                                             |
| [4/6/8 bytes]   | Optional External Tag (VLAN or E-tag).                                                                                                   |
| [4 bytes]       | Optional VLAN.                                                                                                                           |
| 2 bytes         | Ethernet type field equals 0x0800 (MS byte first on the wire).                                                                           |
| 20 bytes        | IPv4 header with no options.                                                                                                             |
| 20 bytes        | Basic TCP header (no options — refer to the rows that follow).                                                                           |
| [10 bytes]      | Optional TCP time stamp header:<br>1 byte Kind 0x08<br>1 byte Length 0x0A<br>4 bytes TS value variable<br>4 bytes TS echo reply variable |

## 7.10.2 Flow Identification and RSC Context Matching

TCP/IP packet's flow is identified by its four tuples: Source/Destination IP Addresses and Source/Destination TCP port numbers. These tuples are compared against the *Flow Identification* fields stored in the active RSC contexts (listed in [Table 7-75](#)). Comparison is done in two phases:

- Hash compare — Hardware computes a hash value of the four tuples for each flow. The hash value is stored in the RSC context table. It is used for silicon optimization of the compare logic. The hash value of the incoming packet is compared against the hash values of all RSC contexts. No match between the two hash values means that there is no valid context of the same flow.
- Perfect Match — Hardware checks the four tuples of the RSC context that passed the first step with the received frame.
  - A match between the two means that an active RSC context is found.
  - Mismatch between the two indicates a hash collision, which causes a completion of the collided RSC.
- In any case of context mismatch, a new context might be opened as described in [Chapter 7.10.3](#).
- If the packet's flow matches an active RSC context, the packet might be appended to the existing RSC as described in [Chapter 7.10.4](#).

**Table 7-75. RSC Context**

| Size                                   | Name       | Description                                                                                                                                                                                                    |
|----------------------------------------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Flow Identification<sup>1</sup></b> |            |                                                                                                                                                                                                                |
| 1 bit                                  | CVALID     | Context valid indication. Set to 1b by hardware when a new context is defined. Cleared to 0b when RSC completes.                                                                                               |
| 1 byte                                 | CHASH      | Context hash value (logic XOR of all bytes of the four tuples).                                                                                                                                                |
| 16 bytes                               | IPDADDR    | IP destination address (set to zero for inactive context).                                                                                                                                                     |
| 16 bytes                               | IPSADDR    | IP source address (set to zero for inactive context).                                                                                                                                                          |
| 1 bit                                  | IP4TYPE    | Defines IP version type (set to 1b for IPv4).                                                                                                                                                                  |
| 2 bytes                                | TCPDPORT   | TCP destination port.                                                                                                                                                                                          |
| 2 bytes                                | TCPSPORT   | TCP source port.                                                                                                                                                                                               |
| 37 bytes                               |            | Total.                                                                                                                                                                                                         |
| <b>RSC Header<sup>2</sup></b>          |            |                                                                                                                                                                                                                |
| 2 bytes                                | RSCIPLN    | Total <i>Length</i> field in the IP header defines the size of the IP datagram (IP header and IP payload) in bytes. Dynamic parameter updated by each received packet.                                         |
| 5 bits                                 | IPOFF      | The word offset of the IP header within the packet that is transferred to the DMA unit.                                                                                                                        |
| 1 bit                                  | RSCTS      | TCP time stamp header presence indication.                                                                                                                                                                     |
| 1 bit                                  | RSCACK     | ACK bit in the TCP header is a dynamic parameter taken from the last coalesced packet.                                                                                                                         |
| 1 bit                                  | RSCACKTYPE | ACK packet type indication (ACK bit is set while packet does not has TCP payload).                                                                                                                             |
| 1 bit                                  | RSCPSH     | PSH bit in the TCP Header is a dynamic parameter which is a logic OR function of the <i>PSH</i> bits in all packets within the Large Receive                                                                   |
| 2 bits                                 | CE, ECT    | ECN bits in the IP.TOS header: <i>CE</i> and <i>ECT</i> .                                                                                                                                                      |
| 4 bytes                                | RSCSEQ     | Non-RSCACKTYPE case: Expected sequence number in the TCP header of the next packet.<br>RSCACKTYPE case: The ACK sequence number in the last good packet.<br>Dynamic parameter updated by each received packet. |

**Table 7-75. RSC Context (Continued)**

| Size                  | Name    | Description                                                                                                                                                                                                                          |
|-----------------------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8 bytes               |         | Total.                                                                                                                                                                                                                               |
| <b>DMA Parameters</b> |         |                                                                                                                                                                                                                                      |
| 7 bits                | RXQUEUE | Receive queue index. This parameter is set by the first packet in the RSC and expected to be the same for all packets in the RSC.                                                                                                    |
| 4 bits                | RSCDESC | Remaining descriptors of this context. The device initialized RSCDESC by the <i>MAXDESC</i> field in the RSCCTL register of the associated receive queue.                                                                            |
| 4 bits                | RSCCNT  | Count the number of packets that are started in the current descriptor. The counter starts at 0x1 for each new descriptor. RSCCNT stops incrementing when it reaches 0xF.                                                            |
| 8 bytes               | HPTR    | Header buffer pointer defines the address in host memory of the large receive header (see <a href="#">Section 7.10.5.2</a> ).                                                                                                        |
| 2 bytes               | DATDESC | Data descriptor is the active descriptor index. Initialized by the first packet in the RSC to the first descriptor. It is updated to the active descriptor at a packet DMA completion.                                               |
| 2 bytes               | DATOFF  | Offset within the data buffer. The data of the first packet in a large receive is the same as the legacy (non-coalescing) definition. Following a DMA completion, it points to the beginning of the data portion of the next packet. |
| 13 bytes              |         | Total.                                                                                                                                                                                                                               |

1. These parameters are extracted from the first packet that opens (activate) the context.
2. All parameters are set by the first packet that opens the context while some are dynamic.

## 7.10.3 Processing New RSC

Defining the RSC context parameters activates a new large receive. If a received packet does not match any active RSC context, the packet starts (opens) a new one. If there is no free context, the oldest active large receive is closed and its evicted context is used for the new large receive.

### 7.10.3.1 RSC Context Setting

The X550 extracts the flow identification and RSC header parameters from the packet that opens the context (the first packet in a large receive that activates an RSC context). The context parameters can be divided into categories: flow identification; RSC header and DMA parameters.

## 7.10.4 Processing Active RSC

Received packets that belong to an active RSC can be added to the large receive if all the following conditions are met:

- The L2 header size equals the size of previous packets in the RSC as recorded in the internal IPOFF parameter in the RSC context table.
- The packet header length as reported in the *HDR\_LEN* field is assumed to be the same as the first packet in the RSC (not checked by hardware).
- The *ACK* flag in the TCP header is equal to the *RSCACK* bit in the RSC context (The value of the *ACK* flag should be constant in all the coalesced packets).
- The packet type remains the same as indicated by the *RSCACKTYPE* bit in the RSC context. Packet type can be either pure ACK packet (with no TCP payload) or other.

- For non-RSCACKTYPE (packet with TCP payload), the sequence number in the TCP header matches the expected value in the RSC context (RSCSEQ).
- For RSCACKTYPE, the Acknowledgment number in the TCP header is greater than the RSCSEQ number in the RSC context. Note that the X550 does not coalesce duplicated ACK nor ACK packets that only updates the TCP window.
- ECN handling: The value of the *CE* and *ECT* bits in the IP.TOS field remains the same as the RSC context and different than 11b.
- The target receive queue matches the RXQUEUE in the RSC context.
- The packet does not include a TCP time stamp header unless it was included on the first packet that started the large receive (indicated by the RSCTS). Note that if the packet includes other option headers than time stamp, NOP or End of option header, the packet is not processed by RSC flow at all.
- The packet fits within the RSC buffer(s).
- If the received packet does not meet any of the above conditions, the matched active large receive is closed. Then hardware opens a new large receive by that packet. Note that since the X550 closes the old large receive it is guaranteed that there is at least one free context.

**Note:** See [Section 7.1.6.2](#) for impact of Time Stamp in packet on RSC decisions.

If the received packet meets all the above conditions, the X550 appends this packet payload to the active large receive and updates the context and header as follows. The packet is then DMA'ed to the RSC buffers (as described in [Section 7.10.5](#)).

- Update the TCP PSH: The *PSH* bit in the Large Receive context gets the value of the *PSH* bit in the TCP header of the received packet.
- Update the expected sequence number for non-RSCACKTYPE: The RSCSEQ in the large receive context is increased by the value of the TCP payload size of the received packet.
- Update the expected sequence number for RSCACKTYPE: The RSCSEQ in the large receive context is updated to the value of the ACK sequence number field in the received packet.
- Update the total length: The RSCIPLN in the large receive context is increased by the value of the TCP payload size of the received packet. The value of the *Total Length* field in the IP header in the received packet gets the updated RSCIPLN. Note that in RSCACKTYPE packets the received payload size is zero.
- Acknowledgment number: If the ACK flag is set, the *Acknowledgment* number field in the header is updated.
- IP header checksum is modified to reflect the changes in the *Total Length* field as follows (note that there is no special process for RSCACKTYPE packets):

$$1's \{ (RSCIPLN - \text{Packet total length}) + 1's (\text{Packet IP header checksum}) \}$$

where:

- Packet total length is the total length value in the received packet.
- Packet IP header checksum stands for the IP header checksum field in the received packet.
- 1's operation defines a ones complement.
- Plus (+) operation is a cyclic plus while the carry out is fed as a carry in.
- TCP header checksum is left as is in the first packet in the RSC and is set to zero on any succeeding packets.

- Update the DMA parameters.
  - The RSCCNT is initialized to 0x1 on each new descriptor. It is then increased by one on each packet that starts on the same descriptor as long as it does not exceed a value of 0xF. When the RSCCNT is set to 0xF (14 packets) the RSC completes.
  - Decrement by one the Remaining Descriptors (RSCDESC) for each new descriptor.
  - Update the receive descriptor index (DATDESC) for each new descriptor.
  - Update the offset within the data buffer (DATOFF) at the end of the DMA to its valid value for the next packet.
- All other fields are kept as defined by the first packet in the large receive.

## 7.10.5 Packet DMA and Descriptor Write Back

The Figure 7-44 shows a top view of the RSC buffers using advanced receive descriptors and header split descriptors.

Figure 7-44. RSC — Header and Data Buffers

### 7.10.5.1 RSC Descriptor Indication (Write Back)

After receiving each packet, the X550 posts the packet data to the data buffers and updates the coalesced header in its buffer. Any completed descriptor is indicated (write back) by setting the fields listed in the following table. A descriptor is defined as the last one when an RSC completes. [Section 7.10.6](#) summarizes all the causes for RSC completion. Any other descriptor in the middle of the RSC is indicated (write back) when the hardware requires the next descriptor so it can report the *NEXTP* field explained in the table that follows.

| Fields on the Last Descriptors of Large Receive                                                                                                                                                 | Fields on All Descriptors Except for the Last One                       |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------|
| <b>EOP</b> : End of packet, and all other fields that are reported together with the EOP.                                                                                                       | <b>NEXTP</b> : Points to the next descriptor of the same large receive. |
| <b>DD</b> : indicates that this descriptor is completed by the hardware and can be processed by the software. The descriptor and the header of the packet may still be updated by the hardware. |                                                                         |
| <b>RSCCNT</b> : indicates the number of coalesced packets in this descriptor.                                                                                                                   |                                                                         |

### 7.10.5.2 Received Data DMA

On the first packet of a large receive, the entire packet is posted to its buffers in host memory. On any other packet, the packet's header and data are posted to host memory as detailed in [Section 7.10.5.3](#) and [Section 7.10.5.4](#).

### 7.10.5.3 RSC Header

The RSC header is stored at the beginning of the first buffer when using advanced receive descriptors, or at the header buffer of the first descriptor when using header split descriptors (it is defined by the internal HPTR parameter in the RSC context). See [Figure 7-44](#) for more details.

The packet's header is posted to host memory after it is updated by the RSC context as follows:

- **Packets with payload coalescing (RSCACKTYPE=0)** — The TCP sequence number is taken from the TCP context (it is taken from the first packet). The *Total Length* field in the IP header is taken from the RSC context (it represent the length of all coalesced packets). The IP checksum is re-calculated. The TCP checksum is set to zero.
- **ACK no payload coalescing (RSCACKTYPE=1)** — The received packet header is posted as is to host memory. Note that if the received packet includes padding bytes, these bytes are posted in the host memory as well.

### 7.10.5.4 Large Receive Data

The data of a coalesced packet is posted to its buffer by the DMA engine as follows:

- Ethernet CRC.
  - When RSC is enabled on any queue, the global CRC strip must be set (HLREG0.RXCRCSTRP=1b).
- Packet data spans on a single buffer.
  - The data of the received packet spans on a single buffer if buffer has the required space.
  - The DMA engine posts the packet data to its buffer pointed to by DATDESC descriptor at an offset indicated by the DATOFF.

- Packet data spans on multiple buffers.
  - The data of the received packet spans across multiple buffers when it is larger than a single buffer or larger than the residual size of the current buffer.
  - When a new buffer is required (new descriptor) the DMA engine writes back to the completed descriptor linking it to the new one ([Section 7.10.5.1](#) details the indicated descriptor fields).
  - Decrement the RSCDESC parameter by one and update the DATDESC for each new opened descriptor.
- DMA completion.
  - Following DMA completion, set the DATOFF to the byte offset of the next packet.
  - If the PSH TCP flag is active in the coalesced packet, the large receive is completed.
- Not enough descriptors in the receive ring buffer.
  - If the SRRCTL[n].DROP\_EN bit on the relevant queue is set, The large receive completes and the new packet is discarded.
  - Otherwise (the DROP\_EN bit is cleared), the packet waits inside the internal packet buffer until new descriptors are added (indicated by the relevant Tail register).
- Not enough descriptors due to RSCDESC exhaust.
  - If the received packet requires more descriptors than indicated by the internal RSCDESC parameter, the X550 completes the current large receive while the new packet starts a new large receive.

## 7.10.6 RSC Completion and Aging

This section summarizes all causes of large receive completion (the first three cases repeat previous sections).

- A packet of a new flow is received while there are no free RSC contexts. The X550 completes (closes) the oldest large receive (opened first). The new packet starts a new large receive using the evicted context.
- Packets with PSH TCP flags can be only the last ones in active large receive.
- The received packet cannot be added to the active large receive due to one of the following cases (indicated also in [Section 7.10.4](#)). In these cases the existing RSC completes and the received packet opens a new large receive.
  - The sequence number does not meet expected value.
  - The receive packet includes a time stamp TCP option header while there was no time stamp TCP option header in the first packet in the RSC.
  - There is not enough space in the RSC buffer(s) for the packet data. Meaning, the received packet requires a new buffer while the RSC already exhausted all permitted buffers defined by the RSCCTL[n].MAXDESC.
  - The received packet requires a new buffer while its descriptor wraps around the descriptor ring.
- When a packets is received while there are no more descriptors in the receive queue and the SRRCTL.DROP\_EN bit is set, the large receive completes and the new packet is discarded.

- EITR expiration while interrupt is enabled — RSC completion is synchronized with interrupt assertion to the host. It enables software to process the received frames since the last interrupt. See more details and EITR setting in [Section 7.3.2.1.1](#).
- EITR expiration while interrupt is disabled — The ITR counter continues to count even when its interrupt is disabled. Every time the timer expires it triggers RSC completion on the associated Rx queues.
- Low number of available descriptors — Whenever crossing the number of free Rx descriptors, the receive descriptor minimum threshold size defined in the SRRCTL[n] registers.
- Interrupt assertion by setting the EICS register has the same impact on packet reception as described in [Section 7.3.1.4.1](#).

**Note:** In some cases packets that do not meet coalescing conditions might have active RSC of the same flow. As an example: received packets with ECE or CWR TCP flags. Such packets bypass completely the RSC logic (posted as single packets), and do not cause a completion of the active RSC. The active RSC would eventually be closed by either reception of a legitimate packet that is processed by the RSC logic but would not have the expected TCP sequence number. Or, an interrupt event closes all RSC's in its Rx queue. When software processes the packets, it gets them in order even though the RSC completes after the previous packet(s) that bypassed the RSC logic.

Any interrupt closes all RSC's on the associated receive queues. Therefore, when ITR is not enabled any receive packet causes an immediate interrupt and receive coalescing should not be enabled on the associated Rx queues.

**Software Note:** Whenever an interrupt is generated all active Large Receives on the relevant queues are completed. The Large Receives are indicated to host memory before the interrupt is asserted.

## 7.11 Fibre Channel over Ethernet (FCoE)

### 7.11.1 Introduction

Fibre Channel (FC) is the predominant protocol used in Storage Area Networks (SAN). Fibre Channel over Ethernet (FCoE) is used to connect an Ethernet storage initiator and legacy FC storage targets.

The FC protocol is based on high reliability of the communication link between the initiator and the storage target. It assumes an extremely low error rate of  $10^{-12}$  and no packet drop. DCB extends Ethernet through class-based flow control in such a way that FC-like no-drop is guaranteed as required by FC. Doing so, FC protocol can be transposed to an Ethernet link by Layer 2 encapsulation that is defined by the FCoE protocol. Figure 7-45 shows a connection between an FCoE initiator and legacy FC targets.

**Figure 7-45. Connecting an FCoE Initiator to FC Targets**

Existing FC HBAs used to connect between an FC initiator and FC targets provide full offload of the FC protocol to the initiator to maximize storage performance. To compete with this market, the X550 offloads the main data path of I/O Read and Write commands to the storage target.

#### 7.11.1.1 FC Terminology

Useful background on FC framing and its Ethernet encapsulation can be found in [Section A.4](#). More comprehensive material can be found in the FIBRE CHANNEL FRAMING AND SIGNALING-2 (FC-FS-2) specification. Following are some of the most common terms used extensively in the sections that describe the FCoE functionality.

- **FC Exchange** — Complete FC read or FC write flow. It starts with a read or write request by the initiator (the host system) until it receives a completion indication from the target (the remote disk).
- **FC Sequence** — An FC exchange is composed of multiple FC sequences. An FC sequence can be single or multiple frames that are sent by the initiator or the target. Also, each FC sequence has a unique sequence ID.

- **FC Frame** — FC frames are the smallest units sent between the initiator and the target. The FC-FS-2 specification defines the maximum frame size as 2112 bytes. Each FC frame includes an FC header and optional FC payload. It also may include extended headers and FC optional headers. Extended headers other than Virtual Fabric Tagging (VFT) are not expected in an FCoE network and FC optional headers are not used in most cases as well.
- **Data Frame** — FC frames that carry read or write data.
- **FCP\_RSP Frame** — FC control frames are sent from the target to the initiator, which defines the completion of an FC read or write exchange.

## 7.11.2 FCoE Transmit Operation

Transmit FCoE offload is enabled by setting the *TUCMD.FCoE* bit in the transmit context descriptor. The X550 supports the following offload capabilities: FC CRC calculation and insertion, FC padding insertion and FC segmentation. These capabilities are described in the following sections.

### 7.11.2.1 FCoE Transmit Cross Functionality

After setting the *TUCMD.FCoE* bit, hardware digests the packet's content before it is sent to the wire. In this case, software must enable hardware offload for additional tasks as follows:

| Cross Function            | Requirements                                                                                                                                                                                                                                                 |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Ethernet CRC insertion    | Software must enable Ethernet CRC insertion by setting the <i>IFCS</i> bit in the transmit data descriptor. The Ethernet CRC covers the entire packet. Enabling FCoE offloading, hardware modifies the packet content and must also adjust the Ethernet CRC. |
| VLAN header               | It is assumed that any FCoE has a VLAN header. In the case of double VLAN mode, the packet must have the two VLAN headers.                                                                                                                                   |
| SNAP packet               | The X550 does not provide FCoE offload for FCoE frame over SNAP.                                                                                                                                                                                             |
| Traffic rate control      | FC traffic relies on a high quality link that guarantees no packet loss. It is expected that any lost traffic protocols supported by the network are enabled by the X550 as well.                                                                            |
| FC and PFC                |                                                                                                                                                                                                                                                              |
| Virtualization            | It is expected that the VMM abstract the FCoE functionality to the VM(s). FCoE setting and FCoE traffic is expected only by the VMM accessing the LAN via the PF.                                                                                            |
| TCP/IP and UDP/IP offload | FCoE traffic is L2 traffic (not over IP). Any setting of TCP/IP and UDP/IP offload capabilities are not applicable and do not impact FCoE offload functions.                                                                                                 |
| Transmit descriptors      | Software must use the advanced transmit descriptor to activate either FC CRC offload or TSO functionality.                                                                                                                                                   |

### 7.11.2.2 FC Padding Insertion

FC frames always consist of a whole number of four bytes. If user data is not composed of a whole number of four bytes, the FC frames contain padding bytes with a zero value. The length of the padding bytes can be any number between zero to three so together with the user data, the length of the FC frames has a whole number of four bytes. The length of the padding bytes is indicated by software in the *Fill Bytes* field in the FC header. This field is used by the receiving end node (target) to extract these bytes. Hardware does not use this field to identify the required length of the padding bytes. Instead, it checks the transmit buffer size indicated by the *PAYLEN* field in the transmit data descriptor. The length of the padding bytes added by hardware equals:

$$2\text{'s complement } \{ \text{two LS bits of } (\text{PAYLEN minus MACLEN}) \}.$$

where *PAYLEN* is defined in the Tx data descriptor and *MACLEN* is defined in the Tx context descriptor.

The X550 auto-pads the frame with the required zero bytes when FCoE offload is enabled (*TUCMD.FCoE* bit is set). In TSO, padding bytes are added only on the last frame since the MSS must be a whole number of four bytes.

### 7.11.2.3 SOF Placement

During a single send, the *SOF* field is taken as is from the FCoE header in the data buffer.

During TSO (both the *TUCMD.FCoE* bit in the transmit context descriptor and the *DCMD.TSE* bit in the transmit data descriptor are set), the *SOF* field in the data buffer is replaced by hardware according to the values of the *SOF* and *ORIS* bits in the transmit context descriptor. In this case the value of the *SOF* field in the data buffer is ignored (for future expansion software should set it to zero). The SOF codes that are inserted to the transmitted packets are stored in the TSOFF register. The TSOFF register contains four SOF codes named as SOF0...SOF3 that are supported by the transmit FCoE offload. By default these values are programmed to the following values: SOF0 = SOFi2; SOF1 = SOFi3; SOF2 = SOFn2; SOF3 = SOFn3. The SOF flag and *Orientation Start* (ORIS) bit in the *FCoEF* field in the transmit context descriptor define an index value. This index is used to extract the SOF code that is inserted to the packet as listed in the [Table 7-76](#). The *ORIS* bit defines if the TSO starts an FC sequence or if the first frame on the FC sequence is already sent.

**Table 7-76. SOF Codes in TSO**

| <b>SOF Bit in the Context Descriptor</b> | <b>ORIS Bit in the Context Descriptor</b> | <b>SOF Code in the First Frame</b> | <b>SOF Code in Other Frames</b> | <b>SOF Code in a Single Packet</b> |
|------------------------------------------|-------------------------------------------|------------------------------------|---------------------------------|------------------------------------|
| 1 (Class 3)                              | 1 (sequence start)                        | SOF1 (SOFi3)                       | SOF3 (SOFn3)                    | SOF1 (SOFi3)                       |
| 1 (Class 3)                              | 0 (not a sequence start)                  | SOF3 (SOFn3)                       | SOF3 (SOFn3)                    | SOF3 (SOFn3)                       |
| 0 (Class 2)                              | 1 (sequence start)                        | SOF0 (SOFi2)                       | SOF2 (SOFn2)                    | SOF0 (SOFi2)                       |
| 0 (Class 2)                              | 0 (not a sequence)                        | SOF2 (SOFn2)                       | SOF2 (SOFn2)                    | SOF2 (SOFn2)                       |

## 7.11.2.4 EOF Insertion

The X550 automatically inserts the *End of Frame* field when the *TUCMD.FCoE* bit in the transmit context descriptor is set.

The *EOF* and *ORIE* fields define the *EOF* that is inserted by hardware. In a single packet send, the *EOF* field is defined completely by the *EOF* setting while in TSO mode, the *EOF* field is defined by the *EOF* and the *ORIE* bits as listed in [Table 7-77](#).

**Table 7-77. EOF Codes in TSO**

| EOF Bits in the Context Descriptor | ORIE Bit in the Context Descriptor | Last Frame of a TSO or TSO in single frame | Other frames of TSO |
|------------------------------------|------------------------------------|--------------------------------------------|---------------------|
| 00 (EOFn)                          | 0 (not a sequence end)             | EOF0 (EOFn)                                | EOF0 (EOFn)         |
|                                    | 1 (sequence end)                   | EOF1 (EOFt)                                | EOF0 (EOFn)         |
| Other                              | X                                  | N/A                                        | N/A                 |

## 7.11.2.5 FC CRC Insertion

FC CRC calculation is one of the most CPU intensive tasks in large transactions. The X550 offloads the FC CRC calculation when the *FCoE* bit is set in the *TUCMD* field within the transmit context descriptor. The X550 calculates and adds the FC CRC before packet transmission but after the required FC padding bytes are already added.

The CRC polynomial used by the FC protocol is the same one as used in FDDI and Ethernet as shown in the following equation. While CRC bytes are transmitted in big endian byte ordering (MS byte first on the wire):

$$X_{32}+X_{26}+X_{23}+X_{22}+X_{16}+X_{12}+X_{11}+X_{10}+X_8+X_7+X_5+X_4+X_2+X+1.$$

The size of FCoE payload on which FC CRC is calculated is indicated in the context and data descriptors as follows. [Figure 7-46](#) specifies the FCoE frame and the relevant parameters to CRC calculation.

**Figure 7-46. FCoE Frame and Relevant Transmit Descriptor Parameters**

### FC CRC Calculation Beginning

FC CRC calculation starts after the FCoE header. It equals to byte offset of *MACLEN* + 4, while the *MACLEN* field in the transmit context descriptor is the byte offset of the last Dword in the FCoE header that contains the SOF flag.

### FC CRC Calculation End

FC CRC calculation ends at the end of the FC Payload LEN shown in [Figure 7-46](#) (eight bytes before the Ethernet CRC).

### 7.11.2.6 Host Data Buffers Content for a Single Packet Send

Table 7-78 lists the data prepared by software when transmit FCoE offload is enabled (the *FCoE* bit in the *TUCMD* field is set in the transmit context descriptor).

**Table 7-78. Transmit FCoE Packet Data Provided by Software (for *TUCMD.FCoE* = 1)**

| Ethernet MAC Addresses | VLAN Header | FCoE Header | FC Frame (provided by software) |           |                     |                          |
|------------------------|-------------|-------------|---------------------------------|-----------|---------------------|--------------------------|
|                        |             |             | [opt.] FC Extended Headers      | FC Header | FC Option Header(s) | [Opt.] Data & FC Padding |

Listed below are fields in the transmitted FCoE frame that are not included in the data buffers (in host memory) as shown in Table 7-78.

- **VLAN Header** — The VLAN header could be part of the data buffer or in the transmit descriptor depending on *VLE* bit in the *CMD* field in the transmit descriptor.
- **EOF** — The EOF is defined by the *EOF* fields and *ORIE* bit in the context descriptor (more details in Section 7.2.3.2.3).
- **FC-CRC** — The X550 calculates and inserts the FC CRC bytes.
- **FC-Padding** — The X550 calculates the padding length and inserts these bytes as required (all zeros).
- **Ethernet CRC** — Insertion should be enabled by the *IFCS* bit in transmit data descriptor.

### 7.11.2.7 FC TSO

FCoE segmentation enables the FCoE software to initiate a transmission of multiple FCoE packets up to a complete FC sequence with a single header in host memory (single instruction). It is activated by using the advanced Tx context descriptor (DTYP equals 0010b) and setting both the *TUCMD.FCoE* in the context descriptor and setting the *DCMD.TSE* bit in the transmit data descriptor. The X550 splits the transmitted content to multiple packets as defined by the *MSS* field in the Tx context descriptor.

#### TSO Parameters

- The frame header includes the Ethernet MAC Addresses, VLAN Tag, FCoE header, and the FC header. The header size is defined by the *HEADLEN* and *MACLEN* in the context descriptor as illustrated in Figure 7-46.
- The *SOF* and *EOF* fields are defined by the *SOF*, *ORIS*, *EOF* and *ORIE* fields in the context descriptor as described in Section 7.11.2.3 and Section 7.11.2.4.
- *MSS* – the maximum segment size in the context descriptor that define the FC data (payload) size on each packet other than the last frame which can be smaller.

### 7.11.2.7.1 Host Data Buffers Content for TSO Offload

Figure 7-47 shows the data in host memory when FCoE TSO is activated. The TSO header is repeated on all frames of the TSO. The header includes static and dynamic fields that are modified by hardware from packet-to-packet. The payload size is reflected in all frames.

Figure 7-47. FCoE TSO Provided by the FCoE Driver

#### FCoE Header

The FCoE packet header must not span more than two buffers. For best bus use it is recommended that the header be located in a single buffer (the first one).

- Ethernet MAC Addresses are the source and destination Ethernet MAC Addresses
- VLAN tag can be provided by the driver as part of the packet header or as part of the data descriptor.
- FCoE header (shown in Figure 7-47) includes the FCoE Ethernet type, FCoE Version and SOF flag. Software should leave the *SOF* fields as zero while hardware inserts it according to the *SOF* and *ORIS* bits in the Tx context descriptor.
- FC (basic) header as shown in Section A.4.2.3.

#### FCoE TSO — Payload

- FC option headers as described in Section A.4.2.5.
- FC data to be segmented
- The payload may or may not include the optional FC padding bytes. Hardware adds any required padding bytes not included in the data buffers according to the *PAYLEN* field in the data descriptor.

Modified fields between consecutive frames within TSO.

**SOF** The SOF flags are defined by the *SOF* bit and *ORIS* bit in the context descriptor (more details in Section 7.11.2.3)

**F\_CTL** Table 7-79 lists those fields in the *F\_CTL* that are modified between consecutive frames of a TSO (see Section A.4.2.3 for a complete description of the *F\_CTL* field). If a TSO is transmitted by a single packet all *F\_CTL* fields are taken from the data buffer (as if it is the last frame in the TSO).

Table 7-79. F\_CTL Codes in TSO

| F_CTL Bits                        | Last Frame in TSO when the <i>ORIE</i> Bit in the Tx Context Descriptor is Set                                                                        | Any Other Frame                                                                                                                         |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| Fill Bytes (1:0)                  | Taken from the F_CTL(1:0) in the data buffer. It defines the length of the FC padding required to make the FC data a complete multiply of four bytes. | 00b if not last frame on TSO or taken from the F_CTL(1:0) in the data buffer if last frame in TSO (even if <i>ORIE</i> bit is not set). |
| Continue Sequence Condition (7:6) | Taken from the F_CTL(7:6) in the data buffer. The continue sequence condition is meaningful only if F_CTL(19) is set and F_CTL(16) is cleared.        | 00b                                                                                                                                     |
| Sequence Initiative (16)          | Taken from the F_CTL(16) in the data buffer. The sequence initiative is meaningful only if F_CTL(19) is also set.                                     | 0b                                                                                                                                      |
| End Sequence (19)                 | Taken from the F_CTL(19) in the data buffer. The end sequence should be set to 1b by software only if the frame is the last one of a sequence.        | 0b                                                                                                                                      |

**DF\_CTL**

Table 7-80 lists those fields in the *DF\_CTL* that can be modified between consecutive frames of a TSO. Note that the *ESP Header Presence* bit is not listed in this table. When *ESP Header* is present, software must not use a TSO that spans across multiple packets. If a TSO is transmitted by a single packet all *DF\_CTL* fields are taken from the data buffer (as if it is the first frame in the TSO).

Table 7-80. DF\_CTL Codes in TSO

| DF_CTL Fields                     | 1st Frame in TSO when <i>ORIS</i> Bit in the Tx Context Descriptor is Set | Any Other Frame |
|-----------------------------------|---------------------------------------------------------------------------|-----------------|
| Device Header Indication (1:0)    | Taken from the data buffer.                                               | 00b             |
| Association Header Indication (4) | Taken from the data buffer.                                               | 0b              |
| Network Header Indication (5)     | Taken from the data buffer.                                               | 0b              |

**SEQ\_CNT**

*SEQ\_CNT* in the first frame is taken from the *SEQ\_CNT* field in the FC header in the data buffers. On any other frame, the value of *SEQ\_CNT* is increased by one from its value in the previous frame. The *SEQ\_CNT* wrap-to-zero after reaching a value of 65,535.

**PARAM**

The *PARAM* field in the first frame is taken from the *PARAM* field in the FC header in the data buffers. If the *FCoEF.PARINC* bit is set in the transmit context descriptor, the value of the *PARAM* becomes dynamic. In that case, the *PARAM* is increased by hardware by the *MSS* value on each frame. Software should set the *FCoEF.PARINC* bit when the *PARAM* field indicates the data offset (*Relative Offset Present* bit in the *F\_CTL* field is set).

**FC\_CRC**

Calculated and inserted on each frame as described in [Section 7.11.2.5](#).

**FC\_Padding**

Calculated the number of required padding bytes and inserted them on the last frame as described in [Section 7.11.2.2](#).

**EOF**

The EOF flags are defined by the *EOF* field and the *ORIE* bit in the context descriptor (more details in [Section 7.11.2.4](#)).

## 7.11.3 FCoE Receive Operation

The X550 can offload the following tasks from the CPU while processing FCoE receive traffic: FC CRC check, receive coalescing and Direct Data placement (DDP). These offload options are described in the sections that follow.

DDP functionality is not provided for control packets or data packets that do not meet DDP criteria (described later in the sections that follow). In those cases, hardware posts the packets to the legacy Rx queues as is (header and trailer are not stripped including SOF, EOF, FC padding and FC CRC bytes). When DDP functionality is enabled, only the FC payload is posted to the user buffers. If the packet's header should be indicated to the legacy Rx queues, all bytes starting at the destination Ethernet MAC Address until the FC header and optionally FC header(s) inclusive are posted to the legacy buffer.

### 7.11.3.1 FCoE Receive Cross Functionality

FCoE receive offload capabilities coexist with other functions in the X550 are listed as follows:

**Table 7-81. FCoE Receive Cross Functionality**

| Cross Function                              | Requirements                                                                                                                                                                                                                                                                                 |
|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Ethernet CRC check                          | There is no enforcement on save bad frames policy. In the case of save bad frames, packets with bad Ethernet CRC are posted to the legacy receive queue even if DDP is enabled. FC payload of bad packets are never posted directly to the user buffers.                                     |
| Ethernet padding extraction                 | There is no enforcement on the Ethernet padding extraction. When DDP is enabled, hardware posts the FC payload to the user buffers. When DDP is not enabled the entire packets are posted to the legacy receive queues with or without the Ethernet padding according to the device setting. |
| VLAN header                                 | It is assumed that any FCoE has a VLAN header. In the case of double VLAN mode, the packet must have the two VLAN headers.                                                                                                                                                                   |
| SNAP packet                                 | The X550 does not provide FCoE offload for FCoE frame over SNAP.                                                                                                                                                                                                                             |
| FC and PFC                                  | FC traffic relies on a high-quality link that guarantees no packet loss. It is expected that any lost traffic protocols supported by the network is enabled by the X550 as well.                                                                                                             |
| Virtualization                              | It is expected that VM(s) generate FC write requests to the VMM. FCoE setting and FCoE traffic is expected only by the VMM accessing the physical function.                                                                                                                                  |
| TCP/IP and UDP/IP offload                   | FCoE traffic is L2 traffic (not over IP). Any setting of TCP/IP and UDP/IP offload capabilities are not applicable and do not impact FCoE offload functions.                                                                                                                                 |
| Jumbo frames                                | Maximum expected clear text FC frame size is 2140 bytes (FC header + FC payload + FC CRC). Adding optional FC crypto, plus FCoE encapsulation, packet might exceed the 2200 bytes. To enable FCoE traffic, jumbo packet reception should be enabled.                                         |
| Receive descriptors in the legacy Rx queues | When FC CRC offload or DDP functionality are enabled, software must use the advanced descriptors in the associated legacy Rx queues (SRRCTL.DESCTYPE = 001b). The legacy Rx buffers must be larger than the maximum expected packet size so any Rx packets span on a single buffer.          |

### 7.11.3.2 FC Receive CRC Offload

FC CRC calculation is one of the most CPU intensive tasks in TSO transactions. The X550 offloads the receive FC CRC integrity check while trashing the CRC bytes and FC padding bytes.

The X550 recognizes FCoE frames in the receive data path by their FCoE Ethernet type and the FCoE version in the FCoE header. The Ethernet type that hardware associates with FCoE is defined in the ETQF register by setting the *FCoE* bit with a specific Ethernet type value. The supported FCoE versions by the Rx offload logic are defined by `FCRXCTRL.FCOEVER`. FCoE packets that do not match the previously described Ethernet type and FCoE versions are ignored by the Rx FCoE logic.

The X550 reconstructs the FC CRC while processing the incoming bytes and compares it against the received FC CRC. The frame is considered a good FC packet if the previous comparison matches and it is considered as a bad FC packet otherwise.

The FC CRC integrity check is meaningful only if all the following conditions are met:

- The received frame contains a correct Ethernet CRC

The length of the FC padding bytes that hardware trashes are defined in the *Fill Bytes* field in the FC frame control (F\_CTL). The *Fill Bytes* field can have any value between zero to three that makes the FC frame a whole number of Dwords. It is expected that the *Fill Bytes* field would be zero except for last data frames within a sequence.

**Figure 7-48. Relevant FCoE and FC Fields for CRC Receive Offload**

### 7.11.3.3 Large FC Receive

Large FC receive includes two types of offloads. The X550 can save a data copy by posting the received FC payload directly to the kernel storage cache or the user application space (in the remainder of the document there is no difference between the two cases and it is named as user buffers). When the packet's payload are posted directly to the user buffers their headers can be posted to the legacy receive queues. The X550 saves CPU cycles by reducing the data copy and also minimize CPU processing by posting only the packet's headers that are required for software.

Figure 7-49 shows the mapping of received FCoE frames to the legacy Rx queue and the user buffers. Figure 7-50 shows a top level overview of the large FC receive flow. The remaining sections detail the large FC receive functionality as follows:

- Enabling large FC receive — [Section 7.11.3.3.1](#)
- FC read exchange flow — [Section 7.11.3.3.2](#)
- FC write exchange flow — [Section 7.11.3.3.3](#)
- FCoE receive filtering (Frame types and rules) — [Section 7.11.3.3.5](#), [Section 7.11.3.3.10](#) and [Section 7.11.3.3.12](#)
- User descriptors — [Section 7.11.3.3.9](#)

- Header posting to the legacy receive queues and FC exceptions — [Section 7.11.3.3.13](#) and [Section 7.11.3.3.14](#)
- Interrupts — [Section 7.11.3.3.15](#)

**Figure 7-49. Large FC Reception to User Buffers and Legacy Rx Queue**

Figure 7-50. FCoE Large Receive Flow Diagram

### 7.11.3.3.1 Enabling Large FC Receive

Large FC receive offload is enabled per each outstanding read or write exchange by programming the FCoE context table with the flow parameters. Setting the FC context for read or write exchange is done at run time. It is expected that a read context is programmed before the read request is initiated to the remote target and write context is programmed before the target sends the ready indication to the initiator. Unless the FC context is invalidated, software must not modify it in the middle of a transaction (see [Section 7.11.3.3.5](#) for details on context invalidation). For more details on FCoE initialization flow see [Section 4.6.9](#).

### 7.11.3.3.2 FC Read Exchange Flow

Figure 7-51 shows an example of an FC (class 3) read request. This flow is detailed in this section.

1. The software checks if the read request can use large FC receive offload depending on FC context resources and some criteria as listed in [Section 7.11.3.3.5](#). [Section 7.11.3.3.12](#) describes a proposed software flow to manage the FC contexts.
2. If the previous conditions are not met, software can still initiate the FC read request according the flow described in [Figure 7-51](#) while the received frames are posted to the legacy receive queues.

- If the previous conditions are met, software locks the relevant user buffers (the target buffers for the FC read request) and program the FC context table. It then initiates the FC read request according the flow shown in [Figure 7-51](#). The payload of the received frames is posted directly to the user buffers. Some of the packet's headers (only the required ones) are posted to the legacy receive queues. The FC header in the packet's header contains the *OX\_ID* field. This field indicates to software its context and its user buffer list. During nominal operation, all packets' headers except packets with FC optional headers are trashed by the hardware minimizing software overhead.
3. The target sends the FCP\_RSP frame type indicating the completion of the read exchange. As a response, the hardware invalidates the FC read context (if it was used) and indicates the number of bytes posted directly to the user buffers in the receive descriptor (see [Section 7.11.3.3.13](#)). Software indicates the read completion to the application.

**Figure 7-51. Example for FC Class 3 Read Exchange Flow**

### 7.11.3.3.3 FC Write Exchange Flow

[Figure 7-52](#) shows an example of an FC (class 3) write request (on which the Seq\_CNT starts from zero on each new sequence). This flow is detailed in the sections that follow.

1. The host (originator) sends an FC write request to the target (responder).
2. Software in the target checks if the write request can use large FC receive offload depending on FC context resources and some criteria as listed in [Section 7.11.3.3.5](#).
3. If the previous conditions are met, software can use DDP for this FC write exchange.
4. The target software locks the relevant user buffers (the target buffers for the FC write request) and program the FC context table. It then initiates the FC ready indication to the host.
5. As a response, the host sends the data frames to be written to the target. The frames are received in the target. If DDP is used, the FC payload is posted directly to the user buffers while “most” (see additional details below) packet's headers are trashed minimizing software overhead.
6. The host marks the last data frame it was requested to send by setting the *Sequence Initiative* bit in the *F\_CTL* field.

7. The target identifies the last data frame and invalidates the DDP context. As indicated above, during nominal operation, “most” packet’s headers are trashed. Only headers that have meaningful content are posted to host memory as: Headers of packets with FC optional headers and the header of the last packet in a sequence with active sequence initiative bit are posted to the legacy receive queues. The hardware indicates the number of bytes posted directly to the user buffers in the receive descriptor (see [Section 7.11.3.3.13](#)). Note that the FC header contains the *RX\_ID* field that can be used by software to identifies its associated DDP context and user buffer list.
8. The target may repeat [Step 4](#), which is followed by [Step 5](#) until the entire requested data is transferred.
9. The target sends the FCP\_RSP frame indicating to the initiator the completion of the write exchange.

**Figure 7-52. Example for FC Class 3 Write Exchange Flow**

#### 7.11.3.3.4 EOF and SOF Flags identification

As part of the DDP functionality, hardware identifies the SOF and EOF flags in the received packets. The flags identification is based on a setting of the RSOFF and REOFF registers. These registers are identical to the TSOFF and TEOFF registers and should be programmed by software to the same values.

#### 7.11.3.3.5 FCoE Receive Filtering

Received FCoE frames are associated to one of the legacy receive queues according to the scheme described in [Section 7.1.3](#). When the legacy receive queue is enabled, large FC receive functionality is enabled as well if a matched FC receive context is defined. The data is posted to the user buffers that are pointed to by the FC receive context. Some of the headers of these frames that are required for the data processing are posted to the legacy receive queue (see [Section 7.11.3.3.13](#)).

FCoE frames that carry FC class 3 or class 2 data can be posted to large receive buffers if they meet the following conditions:

- The FC context table contains valid context that matches the exchange ID in the received frame. Hardware checks the RX\_ID for write data packets sent by the initiator. These packets are identified by the *Exchange Context* bit in the F\_CTL header equals zero (originator of exchange). Hardware checks the OX\_ID for read response data packets sent by the target. These packets are identified by the *Exchange Context* bit in the F\_CTL header equals one (responder of exchange).
- The FC frame source address match the source MAC Address field in the in the same valid exchange ID context.
- Frames are identified as FCoE frame type according to the Ethernet type in the FCoE header. The Ethernet type that hardware associates with FCoE is defined in the ETQF registers by setting the *FCoE* bit with a specific Ethernet type value.
- The FC frame carry class 2 or class 3 content as defined by the SOF flag. The SOF in the FCoE header equals SOFi2 or SOFn2 or SOFi3 or SOFn3.
- The FCoE version in the received frame is equal or lower than FCRXCTRL.FCOEVER.
- The frame contains data content (with data payload) as defined in the *Routing Control* field (R\_CTL) in the FC header:
  - R\_CTL.Information (least significant four bits) equals 0x1 (solicited data).
  - R\_CTL.Routing (most significant four bits) equals 0x0 (device data).
  - Frames that do not contain device data are not posted to the user buffers. Still these frames are compared against the expected SEQ\_ID and SEQ\_CNT in the FC context and update these parameters as described in [Section 7.11.3.3.5](#).
- The FC frame does not include ESP header (bit 6 in the DF\_CTL field within the FC header is cleared). Frames that include ESP option headers are posted to the legacy receive queue. For good use of hardware resources, software should not program the large FC receive context table with flows that carry an ESP header.
- The FC frame does not include FC extended headers. For good use of hardware resources, software should not program the large FC receive context table with flows that carry extended headers.
- The first packet received to a new context is identified as the first FC frame in the exchange. This packet is expected to have the SOFi2 or SOFi3 codes. The SEQ\_ID on the first packet may have any value.
- The frame is received in order as defined in [Section 7.11.3.3.7](#) and does not carry any exception errors as defined in [Section 7.11.3.3.14](#).
- The first frame on each FC sequence is identified by the SOFi2 or SOFi3 codes in the SOF field in the FCoE header. It is expected that the SEQ\_ID is changed for any new sequence.
- The last frame on each FC sequence is identified by an active *End Sequence* flag in the F\_CTL field in the FC header. It is expected to receive the EOFt code in the EOF field; however, hardware does not check this rule.

Other frames (that do not meet the previous conditions) are posted to the legacy receive queues according to the generic Rx filtering rules.

### 7.11.3.3.6 DDP Context

Hardware can provide DDP offload for up to 2048 concurrent outstanding FC read or write exchanges. Each exchange has an associated FC context in hardware. Contexts are identified by the exchange ID (OX\_ID for FC read and RX\_ID for FC write). The exchange ID is a 16-bit field so that a system could theoretically generate up to 64 K concurrent outstanding FC read requests and 64 K concurrent outstanding FC write requests. Hardware contains 2048 contexts for the 2048 concurrent outstanding exchanges. Using exchange ID values between 0 to 2047, software can benefit from the DDP offload. Each entry in the DDP table can be used to offload either a read exchange (as the initiator) or a write exchange (as the target).

Mapping an exchange to a DDP context is done by the exchange ID. The 11 LS bits of the exchange ID is the DDP context Index. In addition, read DDP context is defined by the 11 LS bits of the OX\_ID and write DDP context is defined by the 11 LS bits of the RX\_ID. Therefore, if a specific OX\_ID is offloaded by read DDP, the same number of RX\_ID can't be offloaded by write DDP at the same time.

The FC context is a set of parameters used to identify a frame and its user buffers in host memory. The context parameters are split into two categories (according to the internal hardware implementation): DMA context (FCPTRL, FCPTRH, FCBUFF and FCDMARW registers) and filter context (FCFLT, FCPARAM, SMAC, FCD\_ID, and FCFLTRW registers) as listed in [Table 7-82](#) and shown in [Figure 7-53](#).

Software should program both the DMA context and filter context making the context usable. During reception, hardware updates some of the parameters if the packet matches all criteria detailed in [Section 7.11.3.3.5](#). Initialization values and the updated ones are listed in this section.

**Table 7-82. Large FC Context Table**

| Exchange ID | DMA Context<br>(FCPTRL, FCPTRH, FCBUFF, FCDMARW) |                       | Filter Context<br>(FCFLT, FCFLTRW, FCBUFF) |                                                               |
|-------------|--------------------------------------------------|-----------------------|--------------------------------------------|---------------------------------------------------------------|
|             | DMA Flags                                        | User Descriptor       | Filter Flags                               | In Order Reception                                            |
| 0           | Valid, First, Last, Count                        | Size, Offset, Pointer | Valid, First                               | Seq_ID, Seq_CNT, PARAM, SMAC <sup>1</sup> , D_ID <sup>2</sup> |
| 1           | Valid, First, Last, Count                        | Size, Offset, Pointer | Valid, First                               | Seq_ID, Seq_CNT, PARAM, SMAC <sup>1</sup> , D_ID <sup>2</sup> |

1. If FCRXCTRL.SMAC\_EN is set

2. If FCRXCTRL.DID\_EN is set

**Note:** The WRCONTX field differentiating read and write exchanges is not part of the filter. Thus software should not request a DDP offload of a read flow if a write flow with the same Exchange ID may be received and vice versa.

Table 7-83. FCoE DMA and Filter Contexts

| Field                          | Width (Bits) | Description                                                                                                                                                                                                                                                                                                                                                                                                                          | Initialization Value                  | Updates by Hardware                                                                                                           |
|--------------------------------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| DMA Context Valid <sup>1</sup> | 1            | DMA context is valid.                                                                                                                                                                                                                                                                                                                                                                                                                | 1                                     | Cleared when context is invalidated. See <a href="#">Section 7.11.3.3.10</a> and <a href="#">Section 7.11.3.3.11</a>          |
| Filter Context Valid           | 1            | Filter Context is valid.                                                                                                                                                                                                                                                                                                                                                                                                             | 1                                     |                                                                                                                               |
| Filter First                   | 1            | The first received frame that matches an active context in the filter unit is marked by the filter. This marking is used by the DMA unit as an indication that reception to this context has been started. The DMA context does not accept packets from the filter unit unless it received successfully the packet that was marked as the first one (see the section on exception handling in <a href="#">Section 7.11.3.3.14</a> ). | 0                                     | Hardware sets this bit when the filter unit recognizes the first packet that matches a valid context.                         |
| DMA First                      | 1            |                                                                                                                                                                                                                                                                                                                                                                                                                                      | 0                                     | Hardware sets this bit when the DMA unit received packet that matches a valid context and marked as first by the filter unit. |
| DMA Last                       | 1            |                                                                                                                                                                                                                                                                                                                                                                                                                                      | 0                                     | Hardware sets this bit when the DMA unit received packet that matches a valid context and marked as last by the filter unit.  |
| Buffer Count                   | 8            | Defines the number of remaining user buffers in the list. A value of 0x00 means 1024 buffers                                                                                                                                                                                                                                                                                                                                         | Number of the allocated user buffers. | During reception, hardware decrements the buffer count as each of them completes.                                             |
| Buffer Size                    | 2            | Defines the user buffer size used in this context.<br>00b = 4 KB<br>01b = 8 KB<br>10b = 16 KB<br>11b = 64 KB.<br>All buffers except the first one and the last one are full size. The address of all buffers is aligned to the buffer size in the context. The first buffer can start at a non-zero offset. The size of the last buffer can be smaller than the buffer size as defined by the last buffer size parameter.            | Buffer Size                           | Static Parameter                                                                                                              |
| User Buffer Offset             | 16           | Byte offset within the current buffer to which the next packet should be posted.                                                                                                                                                                                                                                                                                                                                                     | Beginning of the first buffer.        | Next received packet offset.                                                                                                  |

Table 7-83. FCoE DMA and Filter Contexts (Continued)

| Field                 | Width (Bits) | Description                                                                                                                                                                                                                                                                                                                                                                                       | Initialization Value                                                                                               | Updates by Hardware                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Last User Buffer Size | 16           | Size of the last user buffer in byte units.                                                                                                                                                                                                                                                                                                                                                       | Last user buffer size.                                                                                             | Static Parameter                                                                                                                                                                                                                                                                                                                                                                                                                     |
| User Descriptor PTR   | 8            | The user buffers are indicated by a list of pointers named as user descriptors (see <a href="#">Section 7.11.3.3.9</a> for a description of the user descriptors). The user descriptor PTR in the FC context is a pointer to the user descriptor list.                                                                                                                                            | Beginning of the user descriptor list.                                                                             | Hardware increments the user descriptor PTR by eight (the size of the user descriptor) when it completes a buffer and requires the next one.                                                                                                                                                                                                                                                                                         |
| SEQ_ID                | 8            | The sequence ID identifies the received sequence number. An FC read or write exchange can be composed of multiple sequences depending on the target implementation. The SEQ_ID has a different value for each sequence and does not necessarily increment sequentially. Hardware uses the SEQ_CNT and SEC_ID for checking in-order reception as described in <a href="#">Section 7.11.3.3.7</a> . | 0                                                                                                                  | Hardware updates the SEQ_ID in the context table according to the value of the SEQ_ID in the incoming frame.                                                                                                                                                                                                                                                                                                                         |
| SEQ_CNT               | 16           | SEQ_CNT is an index of the expected FC frames within a sequence or within the entire exchange. Hardware uses the SEQ_CNT and SEC_ID for checking in-order reception as described in <a href="#">Section 7.11.3.3.7</a> .                                                                                                                                                                          | Read context: 0<br>Write context: SEQ_CNT + 1 of the last packet of the same exchange received from the initiator. | For each in-order reception, hardware sets SEQ_CNT in the context to the value of the received SEQ_CNT + 1.                                                                                                                                                                                                                                                                                                                          |
| PARAM                 | 32           | The PARAM field in the FC header may indicate the data offset within the FC IO exchange. It is indicated as an offset by the <i>Relative Offset Present</i> bit in the <i>F_CTL</i> field in the FC header. In this case, the PARAM field indicates the expected value of the next received packet.                                                                                               | Read context: 0<br>Write context: the expected received value                                                      | Hardware increments the PARAM by the size of the FC payload if it is used as an offset. The FC payload size equals the packet size minus the length of its header and trailer. While the header for this purpose includes all bytes starting at the Ethernet destination address up to and including the basic FC header, the trailer includes the FC CRC, FC padding, EOF including the three reserved bytes, and the Ethernet CRC. |
| SMAC                  | 48           | Source MAC Address of the FCoE sender. Used to match the source MAC Address of the incoming FCoE packets. The comparison of the SMAC field is enabled by the FCRXCTRL.SMAC_EN bit                                                                                                                                                                                                                 | Source MAC                                                                                                         | Static Parameter                                                                                                                                                                                                                                                                                                                                                                                                                     |
| D_ID                  | 24           | The D_ID field is configured with the FC Destination Identification address of the FCoE receiver and is used to match D_ID value of the incoming FCoE packets. The comparison of the D_ID field is enabled by the FCRXCTRL.DID_EN bit                                                                                                                                                             | D_ID                                                                                                               | Static Parameter                                                                                                                                                                                                                                                                                                                                                                                                                     |
| WRCONTX               | 1            | Write DDP Context. This bit should be set to 1 for write exchange context aimed for target (responder) usage. This bit should be set to 0 for read exchange context aimed for initiator (originator) usage.                                                                                                                                                                                       | WRCONTX                                                                                                            | Static Parameter                                                                                                                                                                                                                                                                                                                                                                                                                     |

1. During programming time, software should enable first the DMA context. When software disables a context it should invalidate first the filter context. See more details on context invalidation in [Section 7.11.3.3.10](#).

### 7.11.3.3.7 In Order Reception Checking

Hardware checks in-order reception by *SEQ\_ID*, *SEQ\_CNT* and *PARAM* fields. These parameters should meet the expected values (as follows) to pass in-order reception's criteria.

- **PARAM** — When the *PARAM* field is used as an offset (as indicated by the *Relative Offset Present* bit in the *F\_CTL* field in the FC header), the *PARAM* field in the received packet should be the same as the *PARAM* field in the FC context. Software should initialize this parameter to the expected received value (equals to zero in read exchanges).
- **SEQ\_ID, SEQ\_CNT** — *SEQ\_ID* identifies the FC sequence and *SEQ\_CNT* is the FC frame index within the entire exchange or within the sequence (according to specific vendor preference). *SEQ\_CNT* in the received packet could be either the same as the *SEQ\_CNT* in the FC context or it could start from zero for new *SEQ\_ID*, which is different than the *SEQ\_ID* in the context. Software should initialize *SEQ\_CNT* to the expected received value (equals zero in read exchanges). *SEQ\_ID* on the first packet is always assumed to be a new value even if by chance it equals to the initial value in the context.

### 7.11.3.3.8 Accessing the Large FC Receive Context

The X550 supports a large number of FC contexts while each context contains about 16 bytes. To save consumed memory space, the FC context is accessed by indirect mapping. This section describes how the DMA and filter contexts are accessed. The DMA context is consist of the *FCPTL*, *FCPTRH* and *FCBUFF* registers while read and write accesses are controlled by the *FCDMARW* register. The filter context is consist of the *FCFLT* register while read and write accesses are controlled by the *FCFLTRW* register.

- **Indirect DMA Context Programming** — Software should program the *FCPTL*, *FCPTRH* and *FCBUFF* registers by the required setting. It then programs the *FCDMARW* register with the following content:
  - *FCOESEL* should be set by the required context index (*OX\_ID* or *RX\_ID* values)
  - The *WE* bit is set to 1b for write access while the *RE* bit is set to 0b. *LASTSIZE* should be set to the relevant value for the context
- **Indirect DMA Context Read** — Software should program the *FCDMARW* register as follows and then read the context on the *FCPTL*, *FCPTRH*, *FCBUFF* and *FCDMARW* registers
  - *FCOESEL* should be set by the required context index (*OX\_ID* or *RX\_ID* values).
  - *RE* bit should be set to 1b for read access while *WE*, and *LASTSIZE* fields are set to 0b. *LASTSIZE* should be set to 0b. It is ignored by hardware when the *RE* bit is set to 1b. When reading *FCDMARW* the *LASTSIZE* field reflects the context content.

The FC context may handle up to 1024 user buffers in a DDP request.

- **Direct DMA Context Access** — Software can access the FCoE DMA context directly for reading or programming through the *FCDDC* registers, each 4 consecutive DWs represent a separate FCoE Context:
  - DW[4\*n]: *FCPTL*[n]
  - DW[4\*n+1]: *FCPTRH*[n]
  - DW[4\*n+2]: *FCBUFF*[n]
  - DW[4\*n+3]: *FCDMARW*[n]

- **Indirect Filter Context Programming** — Software should program the FCFLT register by the required setting. It then programs the FCFLTRW register with the following content:
  - FCOESEL should be set by the required context index (OX\_ID or RX\_ID values).
  - WE bit is set to 1b for a write access while RE bit is set to 0b.
- **Direct Filter Context Access** — Software can access the FCoE Filter Context directly for reading or programming through the FCDFC, FCDFCD registers. FCDFCD has a DW per context while FCDFC is structured such that each 4 consecutive DWs represent a separate FCoE context:
  - FCDFC:
    - DW[4\*n]: FCFLT[n]
    - DW[4\*n+1]: FCPARAM[n]
    - DW[4\*n+2]: FCSMAC[n]
    - DW[4\*n+3]: FCFLTRW[n]
  - FCDFCD:
    - DW[n]: FC D\_ID
- **Indirect Filter Context Read** — Software should program the FCFLTRW register as follows and then read the context on the FCFLT register:
  - FCOESEL should be set by the required context index (OX\_ID or RX\_ID values).
  - RE bit should be set to 1b for a read access while WE bit is set to 0b.

Software should access the FCoE context either through the direct access type or indirect access type. Software mixing the access type accesses results in un-defined outcome.

#### 7.11.3.3.9 User Descriptor Structure and User Descriptor List

The buffers in host memory could be either user application memory or storage cache named as user buffers. In both cases the buffers must be locked (against software) and converted to physical memory up front.

The user descriptor list is a contiguous list of pointers to the user buffers. The buffers are aligned to their size as defined in the FC context. The first buffer can start a non-zero offset as the software defines it in the FC context. All other buffers start at a zero offset. The last buffer can be smaller than the full size as defined in the FC context.

**Table 7-84. FC User Descriptor**

|                                                                                                                                                                                                    |   |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---|
| 63                                                                                                                                                                                                 | 0 |
| User buffer address defined in byte units. N LS bits must be set to zero while N equals 12 for a 4 KB buffer size, 13 for 8 KB buffer size, 14 for 16 KB buffer size and 16 for 64 KB buffer size. |   |

### 7.11.3.3.10 Invalidating FC Read Context

During nominal activity, hardware invalidates autonomously the FC contexts. The target indicates a completion of an FC read by sending the FCP\_RSP frame. Hardware identifies the FCP\_RSP frame and invalidates the FC context that matches the OX\_ID in the incoming frame. The FCP\_RSP frame is posted to the legacy Rx queues with appropriate status indication. Hardware identifies the FCP\_RSP frame by the following criteria:

- The frame is identified as FCoE frame by its Ethernet type
- R\_CTL.Information (least significant four bits) equals 0x7 (command status)
- R\_CTL.Routing (most significant four bits) equals 0x0 (device data)

Context that is invalidated autonomously by hardware is indicated by setting the *FCSTAT* field in the receive descriptor to 10b. When software gets this indication it can unlock the user buffers instantly and re-use the context for a new FC exchange.

In some erroneous cases software might invalidate a context before a read exchange completes (such as a time out event). In such cases, software should clear the *Filter Context Valid* bit and then the *DMA Context Valid* bit. Hardware invalidates the context at a packet's boundaries. Therefore, after software clears the *DMA Context Valid* bit, software should either poll it until it is granted (cleared) by hardware or optionally software could wait ~100 µs (guaranteed time for any associated DMA cycles to complete). In addition, software should also ensure that the receive packet buffer does not contain any residual packets of the same flow. See [Section 4.6.7.1.1](#) for the required software flow. Only then the software can unlock the user buffers and re-use the context for a new FC exchange.

**Note:** While *RXCTRL.RXEN* is in the disabled state, frames from the DDP filter logic may be dropped silently by the device. Therefore, prior to clearing *RXCTRL.RXEN* bit, any outstanding or active DDP context should be invalidated and those associated DDP I/O read requests retried.

### 7.11.3.3.11 Invalidating FC Write Context

During nominal activity, hardware invalidates autonomously the FC contexts. The initiator indicates a completion of a granted portion of an FC write by sending a data frame with active sequence initiative flag. After receiving this type of frame, hardware invalidates the matched FC context. The header of this frame is posted to the legacy Rx queues with appropriate status indication. Hardware identifies this frame by the following criteria:

- The frame is identified as FCoE frame by its Ethernet type
- R\_CTL — Information (least significant four bits) equals 0x1 (solicited data).
- R\_CTL — Routing (most significant four bits) equals 0x0 (device data).
- F\_CTL — Sequence initiative equals 1b indicating transfer initiative to the target.
- F\_CTL — End sequence equals 1b, indicating last frame in a sequence.

Context that is invalidated autonomously by hardware is indicated by setting the *FCSTAT* field in the receive descriptor to 10b. When software gets this indication, it can unlock the user buffers instantly and re-use the context for a new FC exchange. If the FC write is not complete, software can re-use the same context for the completion of the exchange. It can also define a new user buffer list and indicate it to hardware by programming the DMA context. It then can enable the filter context by setting the *Re-Validation* bit the *WE* bit and the *FCOESEL* field in the *FCFLTRW* register.

Software can also invalidate a context in case of a time out event or other reasons. Software invalidation flow is described in [Section 7.11.3.3.10](#).

### 7.11.3.3.12 OX\_ID and RX\_ID Pool Management

As previously indicated, hardware enables Large FC receive offload for up to 2048 concurrent outstanding read or write requests. In some cases more than 2048 concurrent outstanding requests are generated by the FCoE stack. Therefore, software might need to manage two separate queues for the requests: one queue for those FC requested supported by the large FC receive offload and another one for those requests that do not gain the large FC receive offload. Software should claim an entry in the context table, and its associated OX\_ID or RX\_ID for the duration of the read or write requests, respectively. Once a request completes and its context is invalidated, software can re-use its context entry for a new request.

Table 7-85 defines an example for an OX\_ID list that can be used for new FC read requests managed by software at initialization time and during run time. Similarly, this table could be helpful for write requests and their RX\_ID or shared pool for both read and write requests.

**Table 7-85. Software OX\_ID Table**

| Init State of the OX_ID Table | Run-Time Events                                                  | Updated State of the OX_ID Table | Run-Time Events                                                                                               | Updated State of the OX_ID Table | Run-Time Events                                                                                                                                                                                                                                                          | Updated State of the OX_ID Table |
|-------------------------------|------------------------------------------------------------------|----------------------------------|---------------------------------------------------------------------------------------------------------------|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------|
| 0                             | Software is using 50 OX_ID values supported by large FC receive. | 50                               | The following FC read requests are completed (and released by software) in the following order: 44, 21, 9, 0. | 50                               | Software is using additional 50 OX_ID values supported by large FC receive. The following FC read requests are completed (and released by software) in the following order: 75, 10, 38. Ordering between software requests and releases does not matter in this example. | 100                              |
| 1                             |                                                                  | 51                               |                                                                                                               | 51                               |                                                                                                                                                                                                                                                                          | 101                              |

**Note:** Software is aware of which read requests can be offloaded by the large FC receive and use OX\_IDs in the hardware range (0 to 2047) only for those ones.

### 7.11.3.3.13 Packets and Headers Indication in the Legacy Receive Queue

The following packets or packet's headers are posted to the legacy receive queues:

- All FCoE frames that are not offloaded by the DDP logic
- Any packet with exception errors as described in [Section 7.11.3.3.14](#)
- Headers of packets posted to the user buffers by the DDP logic that contain meaningful data (as detailed in [Section 7.11.3.3.2](#) and [Section 7.11.3.3.3](#))

There are a few new fields in the receive descriptor dedicated to FCoE described in [Section 7.1.5.2.2](#):

- **Packet Type** — FCoE packets are identified by their Ethernet type that is programmed in the ETQF registers.
- **FCoE\_PARAM** — Reflects the value of the *PARAM* field in the DDP context.

- **FCSTAT** — FCoE DDP context indication.
- **FCERR** — FCoE Error indication. DDP offload is provided only when no errors are found.
- **FCEOFs and FCEOFe** — Status indication on the *EOF* and *SOF* flags in the Rx packet.

### 7.11.3.3.14 Exception Handling

Table 7-86 lists the exception errors related to FC receive functionality. Packets with any of the following exception errors are posted to the legacy receive queues with no DDP unless specified differently. In these cases, the exception error is indicated in the *Extended Error* field in the receive descriptor. The exceptions are listed in priority order in the table with highest priority first. Other than the EOF exception, any high priority exception hides all other ones with a lower priority.

**Table 7-86. Exception Error Table**

| Event Description                                                                                                              | Actions and Indications                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Unsupported FCoE version (Rx Version > FCRXCTRL.FCOEVER)                                                                       | The packet is identified as an FCoE packet type. DDP context parameters are left intact. Speculative CRC check is done. The packet is posted to legacy Rx queue (unless CRC is incorrect and FCRXCTRL.SAVBAD is not set). If the packet matches the FCoE redirection table, the packet is posted to Rx queue index defined by its OX_ID.<br>RDESC.STATUS.FCSTAT = 00b.<br>RDESC.ERRORS.FCERR = 100b. |
| Rx packet with ESP option header.                                                                                              | If it matches the DDP context, auto invalidate the filter context while keeping the parameters intact. Note that this exception is not expected since software should not enable a context to an exchange that uses ESP encapsulation.<br>RDESC.STATUS.FCSTAT = 00b / 01b / 10b.<br>RDESC.ERRORS.FCERR = 000b.                                                                                       |
| Received EOFa or EOFni or any unrecognized EOF or SOF flags.                                                                   | If it matches the DDP context, auto invalidate the filter context while keeping the parameters intact.<br>RDESC.STATUS.FCSTAT = 00b / 01b / 10b.<br>RDESC.ERRORS.FCERR = 010b (even if no DDP match).<br>RDESC.ERRORS.FCEOFe = 1b.<br>RDESC.STATUS.FCEOFs = 1b.                                                                                                                                      |
| Received non-zero abort sequence condition in FC read exchange.                                                                | If it matches the DDP context, auto invalidate the filter context while keeping the parameters intact.<br>RDESC.STATUS.FCSTAT = 00b / 01b / 10b.<br>RDESC.ERRORS.FCERR = 010b (even if no DDP match).                                                                                                                                                                                                |
| Out of order reception of packet that matches a DDP context <sup>1</sup> .                                                     | Auto invalidate the filter context while keeping the parameters intact.<br>RDESC.STATUS.FCSTAT = 01b.<br>RDESC.ERRORS.FCERR = 100b.                                                                                                                                                                                                                                                                  |
| Received unexpected EOF / SOF:<br>1) New sequence ID and SOF is not SOFi.<br>2) Last packet in a sequence and EOF is not EOFt. | No DDP while filter context is updated (if matched and other parameters are in order).<br>RDESC.STATUS.FCSTAT = 00b / 01b / 10b.<br>RDESC.ERRORS.FCERR = 000b.<br>RDESC.ERRORS.FCEOFe = 1b.<br>RDESC.STATUS.FCEOFs = 0b.                                                                                                                                                                             |
| The DMA unit gets FCoE packets while it missed the packet that was marked as first by the filter unit <sup>2</sup> .           | Filter context parameters are updated while DMA context parameters are left intact.<br>RDESC.STATUS.FCSTAT = 01b / 10b / 11b.<br>RDESC.ERRORS.FCERR = 011b or 101b.                                                                                                                                                                                                                                  |
| Last user buffer is exhausted (not enough space for the FC payload).                                                           | The filter context is updated while DMA context is auto invalidated.<br>RDESC.STATUS.FCSTAT = 01b / 10b / 11b.<br>RDESC.ERRORS.FCERR = 101b.                                                                                                                                                                                                                                                         |

**Table 7-86. Exception Error Table (Continued)**

| Event Description                                                                                                                      | Actions and Indications                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Legacy receive queue is not enabled or no legacy receive descriptor.                                                                   | The entire packet is dropped. Auto invalidates the DMA context while the filter context remains active and continues to be updated regularly. Once legacy descriptors become valid again, packets are posted to the legacy queues with the following indication.<br>RDESC.STATUS.FCSTAT = 01b / 10b / 11b.<br>RDESC.ERRORS.FCERR = 101b.                                                                                                    |
| Packet missed (lost) by the Rx packet buffer. Normally a case when flow control is not enabled or flow control does not work properly. | The entire packet is dropped (by the Rx packet buffer). Auto invalidate the DMA context while the filter context remains active and continues to be updated regularly. Once the Rx packet buffer gets free, further Rx packets are posted to the legacy queues with the following indication.<br>RDESC.STATUS.FCSTAT = 01b / 10b / 11b.<br>RDESC.ERRORS.FCERR = 110b.<br>Note that software might ignore this error when FCSTAT equals 00b. |

1. Out of order might be one of the following cases. SEQ\_CNT does not meet expected value. The *PARAM* field in the Rx packet does not match the DDP context. SEQ\_ID keeps the same value as the previous packet in a new sequence identified by the presence of SOFi code in the *SOF* field. The SOFi is not found in the first FC frame in a context.
2. Lost sync between Filter and DMA contexts could be a result of context invalidation by software together with misbehaved target that sends packet with no host request.

### 7.11.3.3.15 FC Exchange Completion Interrupt

One of the performance indicators of an initiator is measured by the number of I/O operations per second it can generate. The number of FC exchanges per second is affected mainly by the CPU overhead associated with the FC exchange processing and software latencies. The number of concurrent outstanding FC exchanges supported by large FC receive is limited by hardware resources. Reducing the latency associated with processing completions increases the number of FC exchanges per second that the system supports.

## 7.12 Reliability

### 7.12.1 Memory Integrity Protection

All X550 internal memories are protected against soft errors. Most of them are covered by ECC that correct single error per memory line and detect double errors per memory line. Few of the smaller memories are covered by parity protection that detects a single error per memory line.

Single errors in memories with ECC protection are named also as correctable errors. Such errors are silently corrected. Two errors in memories with ECC protection or single error in memories with parity protection are also named as un-correctable errors. Un-correctable errors are considered as fatal errors. If an un-correctable error is detected in Tx packet data, the packet is transmitted with a CRC error. If un-correctable error is detected in Rx packet data, the packet is reported to the host (or manageability) with a CRC error. If an un-correctable error is detected anywhere else, the X550 halts the traffic and sets the ECC error interrupt. Software is then required to initiate a complete initialization cycle to resume normal operation.

### 7.12.2 PCIe Error Handling

For PCIe error events and error reporting see [Section 3.1.5](#).

## 7.13 IPsec Support

### 7.13.1 Overview

This section defines the hardware requirements for the IPsec offload ability included in the X550. IPsec offload is the ability to handle (in hardware) a certain amount of the total number of IPsec flows, while the remaining are still handled by the operating system. It is the operating system's responsibility to submit to hardware the most loaded flows, to take maximum benefits of the IPsec offload in terms of CPU utilization savings. Establishing IPsec Security Associations between peers is outside the scope of this document, since it is handled by the operating system. In general, the requirements on the driver or on the operating system for enabling IPsec offload are not detailed here.

When an IPsec flow is handled in software, since the packet might be encrypted and the integrity check field already valid, and as IPv4 options might be present in the packet together with IPsec headers, the X550 processes it like it does for any other unsupported Layer4 protocol, and without performing on it any layer4 offload.

Refer to [Section 4.6.13](#), for security offload enablement.

### 7.13.2 Hardware Features List

#### 7.13.2.1 Main Features

- Offload IPsec for up to 1024 Security Associations (SA) for each of Tx and Rx:
  - On-chip storage for both Tx and Rx SA tables.
  - Tx SA index is conveyed to hardware via Tx context descriptor.
  - Deterministic Rx SA lookup according to a search key made of SPI, destination IP Address, and IP version type (IPv6 or IPv4).
- IPsec protocols:
  - IP Authentication Header (AH) protocol for authentication.
  - IP Encapsulating Security Payload (ESP) for authentication only.
  - IP ESP for both authentication and encryption, only if using the same key for both.
- Crypto engines:
  - For AH or ESP authentication only: AES-128-GMAC (128-bit key).
  - For ESP encryption and authentication: AES-128-GCM (128-bit key).
- IPsec encapsulation mode: Transport mode, with tunnel mode only in receive.
  - In Tx, packets are provided by software already encapsulated with a valid IPsec header, and:
    - for AH with blank ICV inside.
    - for ESP single send, with a valid ESP trailer and ESP ICV (blank ICV).
    - for ESP large send, without ESP trailer and without ESP ICV.

- In Rx, packets are provided to software encapsulated with their IPsec header and for ESP with the ESP trailer and ESP ICV.
  - where up to 255 bytes of incoming ESP padding is supported, for peers that prefer hiding the packet length.
- IP versions:
  - IPv4 packets that do not include any IP option.
  - IPv6 packets that do not include any extension header (other than AH/ESP extension header).
- Rx status reported to software via Rx descriptor:
  - Packet type: AH/ESP (in the *SECSTAT* field).
  - IPsec offload done (SA match), in the *IPSSA* field.
- One Rx error reported to software via Rx descriptor in the following precedence order: no error, invalid IPsec protocol, packet length error, authentication failed (*SECERR* field).

### 7.13.2.2 Cross Features

- When IPsec offload is enabled, Ethernet CRC must be enabled as well by setting both *TXCRCEN* and *RXCRCSTRP* bits in the *HLREG0* register
- Segmentation: Full coexistence (TCP/UDP packets only).
  - Increment IPsec Sequence Number (SN) and Initialization Vector (IV) on each additional segment.
- Checksum offload: Full coexistence (Tx and Rx)
  - IP header checksum.
  - TCP/UDP checksum.
- IP fragmentation: No IPsec offload done on IP fragments.
- RSS: Full coexistence, hash on the same fields used without IPsec (either 4-tuples or 2-tuples).
- Virtualization:
  - Full coexistence in VMDq mode.
  - in IOV mode, all IPsec registers are owned by the VMM/PF. For example, IPsec can be used for VMotion traffic.
  - No coexistence with VM-to-VM switch, IPsec packets handled in hardware are not looped back by the X550 to another VM. Tx IPsec packets destined to a local VM must be handled in software and looped back via the software switch. However, an anti-spoofing check is performed on any IPsec packet.
- DCB: Full coexistence.
  - Priority flow control, with special care to respect timing considerations.
  - Bandwidth allocation scheme enforced on IPsec packets since 802.1p field is always sent in clear text.
- FCoE: No interaction as FCoE packets are not IP packets.
- RSC: No coexistence.
- Flow director, L3/L4 5-tuple filters, TCP SYN Filter: Full coexistence.

- Jumbo frames: When the `SECTXCTRL.STORE_FORWARD` bit is set (as required for IPsec offload), the maximum supported jumbo packet size is 9.5 KB. This limitation is valid for all packets regardless if they are offloaded by hardware or carry IPsec encapsulation altogether.
- 802.1x: No interaction.
- TimeSync:
  - TimeSync IEEE 1588v1 UDP packets must not be encapsulated as IPsec packets.
  - No interaction with TimeSync 1588v2 Layer2 packets.
- Layer2 encapsulation modes:
  - IPsec offload is not supported for flows with SNAP header.
  - IPsec offload coexists with double VLAN encapsulations.
- Tunneled IPsec packets in receive: IPsec offload supported, but no other Layer4 offload performed.
- NFS and any other Layer5 Rx filter: NFS or Layer5 packets encapsulated over ESP (whether IPsec is offloaded in hardware or not) and over a Layer4 protocol other than TCP are not parsed, nor recognized.
- SCTP Rx offload: Partial coexistence with SCTP CRC32 offload for IPsec-AH packets only.
- SCTP Tx offload: Full coexistence with SCTP CRC32 offload for both IPsec-AH and IPsec-ESP packets.
- Manageability traffic: IPsec offload ability is controlled exclusively by the host, and thus manageability traffic could use IPsec offload only if it is coordinated/configured with/by the host. For IPsec flows handled by software:
  - If manageability and host entities share some IP Address(es), manageability should coordinate any use of IPsec protocol with the host. Note it should be true for previous devices that do not offer IPsec offload.
  - If manageability and host entities have totally separate IP Addresses, manageability can use IPsec protocol (as long as it is handled by the manageability controller software)
- Header split:
  - Supported for SAs handled in hardware, IP boundary split includes the IPsec header.
  - For SAs handled in software, no header split done.
- OS2BMC:
  - As OS2BMC flows that use IPsec can not be offloaded by X550, the driver should make sure it does not accept offload requests for flows to the BMC. To support this, a BMC that uses IPsec should update the `BMCIP` and `BMCIPVAL` registers with the value of the IP Address used by the BMC. After each update, an `EICR.MNG` event is set to indicate to the driver it should read an updated value of the BMC IP Address.
  - Any IPsec offload request, whose destination IP Address matches the BMC IP Address, should be rejected.

### 7.13.3 Software/Hardware Demarcation

The followings items are not supported by hardware but might be supported by operating system/driver:

- Multicast SAs.
- IPsec protocols:
  - Both AH and ESP protocols on the same SA or packet.
  - ESP for encryption only.
  - ESP for authentication and ESP for encryption, each of them using different keys and/or different crypto engines.
- Crypto engines:
  - AES-256, SHA-1, AES-128-CBC, or any other crypto algorithm.
- Tx IPsec packets encapsulated in tunnel mode
- Extended Sequence Number (ESN)
- IP versions:
  - IPv4 packets that include IP option.
  - IPv6 packets that include extension headers other than the AH/ESP extension headers.
- Anti-replay check and discard of incoming replayed packets.
- Discard of incoming dummy ESP packets (packets with protocol value 59).
- IPsec packets that are IP fragments.
- ESP padding content check.
- IPsec statistics.
- IPsec for flows with SNAP header.

**Note:** For SCTP and other Layer4 header types, or for tunneled packets, hardware does not care what is there when doing Rx IPsec processing. Everything after the IP/IPsec headers can be opaque to hardware (consider as IP payload). IPsec processing can be done on any packet that has a matching SA and appropriate IP options/extension headers. There is no expectation that hardware determines what is in the packet beyond the IP/IPsec headers before decrypting/authenticating the packet. The most important point is that hardware should not corrupt or drop incoming IPsec packets — in any situation. When hardware decides and starts performing IPsec offload on a packet, it should pursue the offload until the packet's end — at the price of eventually not doing other Layer3/4 offloads on it. It is always acceptable for hardware not to start doing the IPsec offload on a matched SA, if it knows it is an unsupported encapsulation. For example, one of the three cases: IPv4 option, IPv6 extensions, or SNAP.

## 7.13.4 IPsec Formats Exchanged Between Hardware and Software

This section describes the IPsec packet encapsulation formats used between software and hardware by an IPsec packet concerned with the offload in either Tx or Rx direction.

In Rx direction, the IPsec packets are delivered by hardware to software encapsulated as they were received from the line, whether IPsec offload was done or not, and when it was done, whether authentication/decrypting has succeeded or failed. Refer to the formats described in [Section A.3](#).

### 7.13.4.1 Single Send

In Tx direction, single-send IPsec packets are delivered by software to hardware already encapsulated and formatted with their valid IPsec header and trailer contents, as they should be run over the wire — except for the *ICV* field that is filled with zeros, and the ESP payload destined to be encrypted that is provided in clear text before IPsec encryption.

### 7.13.4.2 Single Send with TCP/UDP Checksum Offload

For single-send ESP packets with TCP/UDP checksum offload, the checksum computing includes the TCP/UDP header and payload before hardware encryption occurred and without the ESP trailer and ESP ICV provided by software. Software provides the length of the ESP trailer plus ESP ICV in a dedicated field of the Tx context descriptor (*IPS\_ESP\_LEN* field) to signal hardware when to stop TCP/UDP checksum computing.

Software calculates a full checksum for the IP pseudo-header as in the usual case. The protocol value used in the IP pseudo-header must be the TCP/UDP protocol value and not the AH/ESP protocol value that appears in the IP header. This full checksum of the pseudo-header is placed in the packet data buffer at the appropriate offset for the checksum calculation.

The byte offset from the start of the DMA'ed data to the first byte to be included in the TCP/UDP checksum (the start of the TCP header) is computed as in the usual case:  $MACLEN + IPLEN$ . It assumes that *IPLEN* provided by software in the Tx context descriptor is the sum of the IP header length with the IPsec header length.

**Note:** For the IPv4 header checksum offload, hardware cannot rely on the *IPLEN* field provided by software in the Tx context descriptor, but should rely on the fact that no IPv4 options are present in the packet. Consequently, for IPsec offload packets, hardware always computes IP header checksum over a fixed amount of 20 bytes.

### 7.13.4.3 TSO TCP/UDP

In Tx direction, TSO IPsec packets are delivered by software to the X550 already encapsulated and formatted with only their valid IPsec header contents — except for the *ICV* field included in AH packets headers that is filled with zeros, and to the ESP payload destined to be encrypted that is provided in clear text before any encryption. No ESP trailer or ESP ICV are appended to TSO by software. It means that hardware has to append the ESP trailer and ESP ICV on each segment by itself, and to update IP total length / IP payload length accordingly.

The next header of the ESP trailer to be appended is taken from *TUCMD.L4T* field of the Tx context descriptor.

By definition TSO requires on each segment that the IP total length / IP payload length be updated, and the IP header checksum and TCP/UDP checksum be re-computed. But for the TSO of IPsec packets, the *SN* and the *IV* fields must be increased by one in hardware on each new segment (after the first one) as well.

Software calculates a partial checksum for the IP pseudo-header as in the usual case. The protocol value used in the IP pseudo-header must be the TCP/UDP protocol value and not the AH/ESP protocol value that appears in the IP header. This partial checksum of the pseudo header is placed in the packet data buffer at the appropriate offset for the checksum calculation.

The byte offset from the start of the DMA'ed data to the first byte to be included in the TCP checksum (the start of the TCP/UDP header) is computed as in the usual case:  $MACLEN + IPLEN$ . It assumes that  $IPLEN$  provided by software in the Tx context descriptor is the sum of the IP header length with the IPsec header length.

For TSO ESP packets, the TCP/UDP checksum computing includes the TCP/UDP header and payload before hardware encryption occurred and without the ESP trailer and ESP ICV appended by hardware. The X550 thus stops TCP/UDP checksum computing after the amount of bytes given by  $L4LEN + MSS$ . It is assumed that the  $MSS$  value placed by software in the Tx context descriptor specifies the maximum TCP/UDP payload segment sent per frame, not including any IPsec header or trailer — and not including the TCP/UDP header.

**Note:** For IPv4 header checksum computing, refer to the note in [Section 7.13.4.2](#).

Shaded fields in the tables that follow correspond to fields that need to be updated per each segment.

| 1 | Security Parameter Index (SPI) |   |      |   |                |    |       |                 |                 |    |    |    |  |
| 2 | Sequence Number (SN)           |   |      |   |                |    |       |                 |                 |    |    |    |  |
| 3 | Initialization Vector (IV)     |   |      |   |                |    |       |                 |                 |    |    |    |  |
| 4 |                                |   |      |   |                |    |       |                 |                 |    |    |    |  |
| 1 | TCP/UDP Header                 |   |      |   |                |    |       |                 |                 |    |    |    |  |
|   | TCP/UDP Payload                |   |      |   |                |    |       |                 |                 |    |    |    |  |

Figure 7-54. IPv4 TSO ESP Packet Provided by Software

**Figure 7-55. IPv6 TSO ESP Packet Provided by Software**

## 7.13.5 Tx SA Table

IPsec offload is supported only via advanced transmit descriptors. See [Section 7.2.3.2.4](#) for details.

### 7.13.5.1 Tx SA Table Structure

The Tx SA table contains additional information required by the AES-128 crypto engine to authenticate and encrypt data. This information is not run over the wire together with the IPsec packets, but is exchanged between the IPsec peers' operating system during the SA establishment process. When the IKE software does a key computation it computes four extra bytes using a pseudo-random function (it generates 20 bytes instead of 16 bytes that it needs to use as a key) and the last four bytes are used as a SALT value.

The SA table in Tx is a 1024 x 20-byte table loaded by software. Each line in the table contains the following fields:

**Table 7-87. Tx SA Table**

| AES-128 KEY | AES-128 SALT |
|-------------|--------------|
| 16 bytes    | 4 bytes      |

Refer to [Section 7.13.7](#) for a description of the way these fields are used by the AES-128 crypto engine.

Each time an unrecoverable memory error occurs when accessing the Tx SA tables, an interrupt is generated and the transmit path is stopped until the host resets X550. Packets that have already started to be transmitted on the wire are sent with a wrong CRC.

Upon reset, the X550 clears the contents of the Tx SA table. Note that access to Tx SA table is not guaranteed for 10  $\mu$ s after the reset command.

### 7.13.5.2 Access to Tx SA Table

#### 7.13.5.2.1 Write Access

1. Software writes the IPSTXKEY 0...3 and/or IPSTXSALT register(s).
2. Software writes the IPSTXIDX register with the *SA\_IDX* field carrying the index of the SA entry to be written, and with the *Write* bit set (*Read* bit cleared).
3. Hardware issues a Write command into the SA table, copying the IPSTXKEY (16 bytes) and the IPSTXSALT (4 bytes) registers into the table entry pointed by the *SA\_IDX* field configured in IPSTXIDX register. It then clears the *Write* bit in IPSTXIDX register.
4. Software starts/resumes sending IPsec offload packets with the *IPsec SA\_IDX* field in the Tx context descriptor pointing to valid/invalid SA entries. A valid SA entry contains updated *KEY* and *SALT* fields currently in use by the IPsec peers.

### 7.13.5.2.2 Read Access

1. Software writes the IPSTXIDX register with the index of the SA entry to be read, and with the *Read* bit set (*Write* bit cleared).
2. Hardware issues a Read command from the SA table, copying into the registers the IPSTXKEY (16 bytes) and the IPSTXSALT (4 bytes) values from the table entry pointed by the *SA\_IDX* field configured in the IPSTXIDX register. It then clears the *Read* bit in IPSTXIDX register.
3. Software reads the IPSTXKEY 0...3 and/or IPSTXSALT register(s).

## 7.13.6 Tx Hardware Flow

### 7.13.6.1 Single Send Without TCP/UDP Checksum Offload

1. Extract IPsec offload request from the *IPSEC* bit of the *POPTS* field in the advanced Tx transmit data descriptor.
2. If IPsec offload is required for the packet (*IPSEC* bit was set), extract the *SA\_IDX*, *Encryption*, and *IPSEC\_TYPE* fields from the Tx context descriptor associated to that flow.
3. Fetch the AES-128 *KEY* and *SALT* from the Tx SA entry indexed by *SA\_IDX* and according to the *Encryption* and *IPSEC\_TYPE* bits to determine which IPsec offload to perform.
4. For AH, zero the mutable fields.
5. Compute ICV and encryption data (if required for ESP) over the appropriate fields as specified in [Section A.3](#), according to the operating rules described in [Section 7.13.7](#), and making use of the AES-128 *KEY* and *SALT* fields fetched in [Step 3](#).
6. Insert ICV at its appropriate location and replace the plaintext with the ciphertext (if required for ESP), as specified in [Section A.3](#).

### 7.13.6.2 Single Send With TCP/UDP Checksum Offload

1. Extract the IPsec offload command from the *IPSEC* bit of the *POPTS* field in the advanced Tx transmit data descriptor.
2. If IPsec offload is required for the packet (*IPSEC* bit was set), extract the *SA\_IDX*, *Encryption*, *IPSEC\_TYPE*, and *IPS\_ESP\_LEN* fields from the Tx context descriptor associated to that flow.
3. Fetch the AES-128 *KEY* and *SALT* from the Tx SA entry indexed by *SA\_IDX*, and according to the *Encryption* and *IPSEC\_TYPE* bits to determine which IPsec offload to perform.
4. Compute the byte offset from the start of the DMA'ed data to the first byte to be included in the checksum (the start of the TCP header) as specified in [Section 7.13.4.2](#).
5. Compute TCP/UDP checksum until either the last byte of the DMA data or for ESP packets, up to *IPS\_ESP\_LEN* bytes before it. As in the usual case, *implicitly* pad out the data by one zeroed byte if its length is an odd number.
6. Sum the full checksum of the IP pseudo header placed by software at its appropriate location with the TCP/UDP checksum computed in [Step 5](#). Overwrite the checksum location with the 1's complement of the sum.
7. For AH, zero the mutable fields.

8. Compute ICV and encrypt data (if required for ESP) over the appropriate fields as specified in [Section A.3](#), according to the operating rules described in [Section 7.13.7](#), and making use of the AES-128 *KEY* and *SALT* fields fetched in [Step 3](#).
9. Insert ICV at its appropriate location and replace the plaintext with the ciphertext (if required for ESP), as specified in [Section A.3](#).

### 7.13.6.3 TSO TCP/UDP

1. Extract the IPsec offload command from the *IPSEC* bit of the *POPTS* field in the advanced Tx transmit data descriptor.
2. If IPsec offload is required for the packet (*IPSEC* bit was set), extract the *SA\_IDX*, *Encryption*, and *IPSEC\_TYPE* fields from the Tx context descriptor associated to that flow.
3. Fetch the AES-128 *KEY* and *SALT* from the Tx SA entry indexed by *SA\_IDX*, and according to the *Encryption* and *IPSEC\_TYPE* bits to determine which IPsec offload to perform.
4. Fetch the packet header from system memory, up to *IPLen*+*L4Len* bytes from the start of the DMA'ed data.
5. Overwrite the TCP SN with the stored accumulated TCP SN (if it is not the first segment).
6. Fetch (next) MSS bytes (or the remaining bytes up to *PAYLEN* for the last segment) from system memory and from the segment formed by packet header and data bytes, while storing the accumulated TCP SN.
7. Compute the byte offset from the start of the DMA'ed data to the first byte to be included in the checksum (the start of the TCP header) as specified in [Section 7.13.4.3](#).
8. Compute TCP/UDP checksum until the last byte of the DMA data. As in the usual case, *implicitly* pad out the data by one zeroed byte if its length is an odd number.
9. For both IPv4 and IPv6, hardware needs to factor in the TCP/UDP length (typically *L4Len*+*MSS*) to the software-supplied pseudo header partial checksum. It then sums to obtain a full checksum of the IP pseudo header with the TCP/UDP checksum computed in [Step 7](#). Overwrite the TCP/UDP checksum location with the 1's complement of the sum.
10. Increment by one the *AH/ESP SN* and *IV* fields on every segment (except the first segment), and store the updated *SN* and *IV* fields with other temporary statuses stored for that TSO (one TSO set of statuses per Tx queue).
11. For ESP, append the ESP trailer: 0-3 padding bytes, padding length, and next header = TCP/UDP protocol value, in a way to get the 4-byte alignment as described in [Section 7.13.4.3](#).
12. Compute the IP total length / IP payload length and compute IPv4 header checksum as described in the note of [Section 7.13.4.1](#). Place the results in their appropriate location.
13. For AH, zero the mutable fields.
14. Compute ICV and encryption data (if required for ESP) over the appropriate fields as specified in [Section A.3](#), according to the operating rules described in [Section 7.13.7](#), and making use of the AES-128 *KEY* and *SALT* field fetched in [Step 3](#).
15. Insert ICV at its appropriate location and replace the plaintext with the ciphertext (if required for ESP), as specified in [Section A.3](#).
16. Go back to [Step 4](#) to process the next segment (if necessary).

## 7.13.7 AES-128 Operation in Tx

The AES-128-GCM crypto engine used for IPsec is referred throughout the document as an AES-128 black box, with 4-bit string inputs and 2-bit string outputs, as shown in Figure 7-56. Refer to the GCM specification for the internal details of the engine. The difference between IPsec modes resides in the set of inputs presented to the box.

**Figure 7-56. AES-128 Crypto Engine Box**

- **Key** — 128-bits AES-128 *KEY* field (secret key) stored for that IPsec flow in the Tx SA table:

Key = AES-128 KEY

- **Nonce** — 96-bits initialization vector used by the AES-128 engine, which is distinct for each invocation of the encryption operation for a fixed key. It is formed by the AES-128 *SALT* field stored for that IPsec flow in the Tx SA table, appended with the *Initialization Vector (IV)* field included in the IPsec packet:

Nonce = [AES-128 SALT, IV]

The nonce, also confusingly referred as IV in the GCM specification, is broken into two pieces — a fixed random part salt and increasing counter part IV, so the salt value goes with the packet as the fixed part. The purpose behind using the salt value is to prevent offline dictionary-type attacks in hashing case, to prevent predictable patterns in the hash.

- **AAD** — Additional Authentication Data input, which is authenticated data that must be left un-encrypted.
- **Plaintext** — Data to be both authenticated and encrypted.
- **Ciphertext** — Encrypted data, whose length is exactly that of the plaintext.
- **ICV** — 128-bit Integrity Check Value (referred also as authentication tag).
- **H** — is internally derived from the key.

**Note:** The square brackets in the formulas is used as a notation for concatenated fields.

### 7.13.7.1 AES-128-GCM for ESP — Both Authenticate and Encryption

AAD = [SPI, SN]

Plaintext = [TCP/UDP header, TCP/UDP payload, ESP trailer]

**Note:** Unlike other IPsec modes, in this mode, the *IV* field is used only in the nonce, and it is not included in either the plaintext or the AAD inputs.

ESP trailer does not include the *ICV* field. Refer to [Section A.3.2](#).

### 7.13.7.2 AES-128-GMAC for ESP — Authenticate Only

AAD = [SPI, SN, IV, TCP/UDP header, TCP/UDP payload, ESP trailer]

Plaintext = [] = empty string, no plaintext input in this mode

**Note:** ESP trailer does not include the *ICV* field. Refer to [Section A.3.2](#).

### 7.13.7.3 AES-128-GMAC for AH — Authenticate Only

AAD = [IP header, AH header, TCP/UDP header, TCP/UDP payload]

Plaintext = [] = empty string, no plaintext input in this mode

**Note:** Both IP header and AH header contain mutable fields that must be zeroed prior to be entered into the engine. Refer to [Section A.3.1](#). Among other fields, the AH header includes *SPI*, *SN*, and *IV* fields.

## 7.13.8 Rx Descriptors

IPsec offload is supported only via advanced receive descriptors. See [Section 7.1.5.2](#) for details.

## 7.13.9 Rx SA Tables

### 7.13.9.1 Rx SA Tables Structure

The Rx SA tables contain additional information required by the AES-128 crypto engine to authenticate and decrypt the data. This information is not run over the wire together with the IPsec packets, but is exchanged between the IPsec peers' operating system during the SA establishment process. When the IKE software does a key computation it computes four extra bytes using a pseudo-random function (it generates 20 bytes instead of 16 bytes that it needs to use as a key) and the last four bytes are used as a salt value.

SPI is allocated by the receiving operating system in a unique manner. However, in a virtualized context, guest operating systems can allocate SPI values that collide with the SPI values allocated by the VMM/PF. Consequently, the SPI search must be completed by comparing the destination IP Address with the IP Addresses of the VMM/PF, which are stored in a separate table. Guest operating systems could thus use the proposed IPsec offload as long as their SAs are configured via the VMM/PF. It is assumed that refreshing the SAs would be done once every several minutes, and would thus not overload the VMM/PF.

There are three Rx SA tables in the X550:

- IP Address table — 128 entries
- SPI table — 1K entries
- KEY table — 1K entries

They are loaded by software via indirectly addressed CSRs, as described in [Section 7.13.9.2](#).

**Table 7-88. IP Address Table**

|            |
|------------|
| IP Address |
| 16 bytes   |

**Table 7-89. SPI Table**

|         |                                          |
|---------|------------------------------------------|
| SPI     | IP Index<br>(points to IP Address table) |
| 4 bytes | 1 bytes                                  |

**Table 7-90. KEY Table**

|            |             |              |
|------------|-------------|--------------|
| IPsec Mode | AES-128 KEY | AES-128 SALT |
| 1 byte     | 16 bytes    | 4 bytes      |

The *IPsec Mode* field contains the following bits:

- VALID
- IPv6
- PROTO
- DECRYPT

It is assumed that the SPI and IP Address tables are implemented internally in CAM cells, while the KEY table uses RAM cells. When an incoming IPsec packet (which does not include option in IPv4 or another extension header in IPv6) is detected, hardware first looks up for the destination IP Address to match one of the IP Addresses stored in the IP Address table. If there is a match, the index of that IP Address match is used together with the *SPI* field extracted from the packet for a second lookup into the SPI table. If there is again a match, the index of that SPI+IP Index match is used to retrieve the SA parameters from the KEY table. The packet is finally considered to get an SA match only after inspecting the corresponding entry in the KEY table, as long as all the following conditions are met:

- *Valid* bit is set
- *IPv6* bit match with the IP version (IPv6/IPv4) of the incoming IPsec packet
- *Proto* bit match with the AH/ESP type of the incoming IPsec packet

Each time an unrecoverable memory ECC error occurs when accessing one of the Rx SA tables, an interrupt is generated and the receive path is stopped until the host resets X550.

Upon reset, the X550 clears the contents of the Rx KEY table and software is required to invalidate the entire IP Address and SPI CAM tables by clearing their contents. Access to Rx SA tables is not guaranteed for 10  $\mu$ s after the Reset command.

## 7.13.9.2 Access to Rx SA Tables

### 7.13.9.2.1 Write Access

1. Software writes the IP Address table via the IPSRXIPADDR 0...3 registers
2. Software writes the IPSRXIDX register with the following:
  - a. *Table* bits combination corresponding to the Rx SA table to be written (such as 01b for IP Address table)
  - b. *TB\_IDX* field pointing to the index to be written within the table
  - c. *Write* bit set (*Read* bit cleared)
3. Hardware issues a Write command into the Rx SA table pointed by the *Table* bits combination, copying the concerned register(s) into the entry pointed by the *TB\_IDX* field configured in the IPSRXIDX register. It then clears the *Write* bit in IPSRXIDX register.
4. Software performs steps 1 to 3 twice, first for writing the SPI table via IPSRXSPI, IPSRXIPIDX registers, and second for writing the KEY table via IPSRXKEY 0...3, IPSRXSALT, and IPSRXMOD registers.

Each time an entry in the IP Address or SPI table is not valid/in-use anymore, software is required to invalidate its content by clearing it. For the IP table, an entry must be invalidated by software each time there is no more SPI entry that points to it; while for the SPI table, software must invalidate any entry as soon as it is not valid/not used anymore.

### 7.13.9.2.2 Read Access

1. Software writes the IPSRXIDX register with the *Table* and *TB\_IDX* fields corresponding to the Rx SA table and entry to be read, and with the *Read* bit set (*Write* bit cleared).
2. Hardware issues a Read command from the Rx SA table and entry pointed by *Table* bits combination and *TB\_IDX* field, copying each field into its corresponding register. It then clears the *Read* bit in IPSRXIDX register.
3. Software reads the corresponding register(s).

**Caution:** There is an internal limitation in that only one single Rx SA table can be read accessed by software at a time. Hence, it is recommended that the entire read process, from steps 1 to 3, be repeated successively for each Rx SA table separately.

## 7.13.10 Rx Hardware Flow without TCP/UDP Checksum Offload

1. Detect an IPsec header not encapsulated over a SNAP header is present without any IPv4 option or other IPv6 extension header encapsulated before it, and determine its type AH/ESP.
2. If such an IPsec header is present (as announced by the IP protocol field for IPv4 or by the next header for IPv6), extract the SPI, destination IP Address, and IP version (IPv4 or IPv6), and use these fields for the lookups into the Rx SA tables as described in [Section 7.13.9.1](#). Also report the IPsec protocol found in the *Security* bits of the *Extended Status* field in the advanced Rx descriptor.

3. If there is a SA match for that packet, fetch the IPsec Rx mode from the SA entry, and according to the *Proto* and *Decrypt* bits determine which IPsec offload to perform. Also, set the *IPSSA* bit of the *Extended Status* field in the advanced Rx descriptor. If there was no SA match, clear the *IPSSA* bit, report no error in *Security Error* bits of the *Extended Errors* field in the advanced Rx descriptor, and stop processing the packet for IPsec.
4. If the *Proto* field recorded in the Rx SA table does not match the *IP Protocol* field (next header for IPv6) seen in the packet, report it via the *Security Error* bits of the *Extended Errors* field in the advanced Rx descriptor, and stop processing the packet for IPsec.
5. Fetch the AES-128 KEY and Salt from the matched Rx SA entry.
6. For AH, zero the mutable fields.
7. Make sure the AH/ESP header is not truncated, and for ESP, make sure the packet is 4-bytes aligned. If not, report it via the *Security error* bits of the *Extended Errors* field in the advanced Rx descriptor, but processing of the packet for IPsec might be completed (if it has already started). A truncated IPsec packet is a valid Ethernet frame (at least 64 bytes) shorter than:
  - a. ESP – at least 40 bytes following the IP header (16 [ESP header] + 4 [min. padding, pad\_len, NH] + 16 [ICV] + 4 [CRC])
  - b. AH over IPv4 – at least 40 bytes following the IP header (20 [AH header] + 16 [ICV] + 4 [CRC])
  - c. AH over IPv6 – at least 44 bytes following the IP header (20 [AH header] + 4 [ICV padding] + 16 [ICV] + 4 [CRC])
8. Compute ICV and decrypt data (if required for ESP) over the appropriate fields as specified in [Section A.3](#), according to the operating rules described in [Section 7.13.12](#), and making use of the AES-128 KEY and SALT fields fetched in [Step 5](#).
9. Compare the computed ICV with the ICV field included in the packet at its appropriate location as specified in [Section A.3](#), and report the comparison status match/fail via the *Security Error* bits of the *Extended Errors* field in the advanced Rx descriptor.

### 7.13.11 Rx Hardware Flow with TCP/UDP Checksum Offload

Perform the Rx hardware flow described in [Section 7.13.10](#) and add the following steps:

1. Start computing the checksum from the TCP/UDP header's beginning — found according to the Rx parser logic updated for IPsec formats described in [Section A.3](#). Do not perform Layer4 offloads if unsupported IPsec encapsulation is detected. For example, tunneled IPsec, IPv4 options or IPv6 extensions after the IPsec header.
2. For ESP, stop checksum computing before the beginning of the ESP trailer — found from the end of packet according to the padding length field content, and to the formats described in [Section A.3.2](#). As in the usual case, *implicitly* pad out the data by one zeroed byte if its length is an odd number.
3. Store the next header extracted from the AH header/ESP trailer into the *Packet Type* field of the advanced Rx descriptor, but use the TCP/UDP protocol value in the IP pseudo header used for the TCP/UDP checksum. Also compute the TCP/UDP packet length to be inserted in the IP pseudo header (excluding any IPsec header or trailer).
4. Compare the computed checksum value with the TCP/UDP checksum included in the packet. Report the comparison status in the *Extended Errors* field of the advanced Rx descriptor.

## 7.13.12 AES-128 Operation in Rx

The AES-128 operation in Rx is similar to the operation in Tx, while for decryption, the encrypted payload is fed into the plaintext input, and the resulted ciphertext stands for the decrypted payload. Refer to [Section 7.13.7](#) for the proper inputs to use in every IPsec mode.

### 7.13.12.1 Handling IPsec Packets in Rx

Table 7-91 lists how IPsec packets are handled according to some of their characteristics.

**Table 7-91. Summary of IPsec Packets Handling in Rx**

| IP Fragment | IPv4 Option or IPv6 Extensions or SNAP | IP Version | SA Match   | IPsec Offload in Hardware | Layer4/3 Offload in Hardware | Header Split                                            | AH/ESP Reported in Rx Desc. |
|-------------|----------------------------------------|------------|------------|---------------------------|------------------------------|---------------------------------------------------------|-----------------------------|
| Yes         | Yes                                    | v4         | Don't care | No                        | IP checksum only             | Up to IPsec header included                             | Yes                         |
| Yes         | Yes                                    | v6         | Don't care | No                        | No                           | Up to IP fragment extension included                    | No                          |
| Yes         | No                                     | v4         | Don't care | No                        | IP checksum only             | Up to IPsec header included                             | Yes                         |
| No          | Yes                                    | v4         | Don't care | No                        | IP checksum only             | No                                                      | Yes                         |
| No          | Yes                                    | v6         | Don't care | No                        | No                           | Up to first unknown or IPsec extension header, excluded | No <sup>1</sup>             |
| No          | No                                     | v4         | Yes        | Yes                       | Yes <sup>2</sup>             | Yes <sup>3</sup>                                        | Yes                         |
| No          | No                                     | v4         | No         | No                        | IP checksum only             | No                                                      | Yes                         |

## 8.0 Programming Interface

### 8.1 General

The X550's address space is mapped into four regions with PCI Base Address Registers listed in [Table 8-1](#) and explained more in [Section 9.2.2.16](#) and [Section 9.2.2.17](#).

**Table 8-1. X550 Address Regions**

| Addressable Content                                     | Mapping Style        | Region Size                    |
|---------------------------------------------------------|----------------------|--------------------------------|
| Internal registers memories and NVM (Memory BAR)        | Direct memory mapped | 128 KB + NVM Size <sup>1</sup> |
| FLASH (optional) <sup>2</sup>                           | Direct memory mapped | 2 MB - 4 MB                    |
| Expansion ROM (optional)                                | Direct memory mapped | 64 KB - 512 KB                 |
| Internal registers and memories (optional) <sup>3</sup> | I/O window mapped    | 32 bytes                       |
| MSI-X (optional)                                        | Direct memory mapped | 16 KB <sup>4</sup>             |

1. The Flash size is defined by the BARCTRL register.
2. The Flash space in the Memory CSR and Expansion ROM Base Address are mapped to different Flash memory regions. Accesses to the Memory BAR at offset 256 KB are mapped to the Flash device at offset 0x0, while accesses to the Expansion ROM at offset 0x0 are mapped to the Flash region pointed by the PXE Driver Module Pointer (read from NVM word address 0x05). See [Section 6.1](#). The Expansion ROM region has a size limited to 512 KB.
3. The internal registers and memories can be accessed through I/O space as explained in the sections that follow.
4. See [Section 9.2.2.16](#) for the MSI-X BAR offset in 32-bit and 64-bit BAR options.

#### 8.1.1 Memory-Mapped Access

##### 8.1.1.1 Memory-Mapped Access to Internal Registers and Memories

The internal registers and memories can be accessed as direct memory-mapped offsets from the Memory CSR BAR. See the following sections for detailed description of the Device registers.

In IOV mode, this area is partially duplicated per VF. All replications contain only the subset of the register set that is available for VF programming.

##### 8.1.1.2 Memory-Mapped Accesses to Flash

The external Flash can be accessed using direct memory-mapped offsets from the CSR base address register (BAR0/BAR1).

### 8.1.1.3 Memory-Mapped Access to MSI-X Tables

The MSI-X tables can be accessed as direct memory-mapped offsets from the base address register (BAR3). The MSI-X registers are described in [Section 8.2.4.1, “MSI-X Table Registers”](#).

In IOV mode, this area is duplicated per VF.

### 8.1.1.4 Memory-Mapped Access to Expansion ROM

The option ROM module located in the external Flash can also be accessed as a memory-mapped expansion ROM. Accesses to offsets starting from the Expansion ROM Base address reference the Flash, provided that access is enabled through the NVM Initialization Control Word, and if the Expansion ROM Base Address register contains a valid (non-zero) base memory address.

## 8.1.2 I/O-Mapped Access

All internal registers and memories can be accessed using I/O operations. I/O accesses are supported only if an I/O Base Address is allocated and mapped (BAR2), the BAR contains a valid (non-zero value), and I/O address decoding is enabled in the PCIe configuration.

When an I/O BAR is mapped, the I/O address range allocated opens a 32-byte window in the system I/O address map. Within this window, two I/O addressable registers are implemented: IOADDR and IODATA. The IOADDR register is used to specify a reference to an internal register or memory, and then the IODATA register is used to access it at the address specified by IOADDR:

**Table 8-2. I/O Map**

| Offset    | Abbreviation | Name                                                                                                                                                                                        | RW | Size    |
|-----------|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----|---------|
| 0x00      | IOADDR       | Internal Register, Internal Memory, or Flash Location Address.<br>0x00000-0x1FFFF – Internal registers/memories<br>0x20000-0x7FFFF – Undefined                                              | RW | 4 bytes |
| 0x04      | IODATA       | Data field for reads or writes to the internal register, internal memory, or Flash location as identified by the current value in IOADDR. All 32 bits of this register are read/write-able. | RW | 4 bytes |
| 0x08-0x1F | Reserved     | Reserved.                                                                                                                                                                                   | O  | 4 bytes |

### 8.1.2.1 IOADDR (I/O Offset 0x00; RW)

The IOADDR register must always be written as a Dword access. Writes that are less than 32 bits are ignored. Reads of any size returns a Dword of data. However, the chipset or CPU might only return a subset of that Dword.

For software programmers, the IN and OUT instructions must be used to cause I/O cycles to be used on the PCIe bus. Because writes must be to a 32-bit quantity, the source register of the OUT instruction must be EAX (the only 32-bit register supported by the OUT command). For reads, the IN instruction can have any size target register, but it is recommended that the 32-bit EAX register be used.

Bits 31 through 20 are ignored by the device and should be set to zero by the software. At hardware reset (LAN\_PWR\_GOOD) or PCI reset, this register value resets to 0x00000000. Once written, the value is retained until the next write or reset.

### 8.1.2.2 IODATA (I/O Offset 0x04; RW)

The IODATA register must always be written as a Dword access when the IOADDR register contains a value for the internal register and memories (such as 0x00000-0x1FFFC). In this case, writes that are less than 32 bits are ignored.

Writes and reads to IODATA when the IOADDR register value is in an undefined range (0x20000-0x7FFFC) should not be performed. Results cannot be determined.

**Note:** There are no special software timing requirements on accesses to IOADDR or IODATA. All accesses are immediate except when data is not readily available or acceptable. In this case, the X550 delays the results through normal bus methods (like split transaction or transaction retry).

Because a register/memory read or write takes two I/O cycles to complete, software must provide a guarantee that the two I/O cycles occur as an atomic operation. Otherwise, results can be non-deterministic from the software viewpoint.

### 8.1.2.3 Undefined I/O Offsets

I/O offsets 0x08 through 0x1F are considered to be reserved offsets with the I/O window. Dword reads from these addresses return 0xFFFF, while writes to these addresses are discarded.

## 8.1.3 Configuration Access to Internal Registers and Memories

To support legacy pre-boot 16-bit operating environments without requiring I/O address space, the X550 enables accessing CSRs via the configuration address space by mapping IOADDR and IODATA registers into the configuration address space. The register mapping in this case is listed in [Table 8-3](#).

**Table 8-3. IOADDR and IODATA in Configuration Address Space**

| Configuration Address | Abbreviation | Name                                                                                                                                                                                           | RW | Size    |
|-----------------------|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----|---------|
| 0x98                  | IOADDR       | Internal register or internal memory location address.<br>0x00000-0x1FFFF – Internal registers and memories.<br>0x20000-0x7FFFF – Undefined.                                                   | RW | 4 bytes |
| 0x9C                  | IODATA       | Data field for reads or writes to the internal register or internal memory location as identified by the current value in IOADDR. All 32 bits of this register can be read from or written to. | RW | 4 bytes |

Software writes data to an internal CSR via the configuration space in the following manner:

1. CSR address is written to the IOADDR register where:
  - Bit 31 (IOADDR.*Configuration IO Access Enable*) of the IOADDR register should be set to 1b.
  - Bits 30:0 of IOADDR should hold the actual address of the internal register or memory being written to.
2. Data to be written is written into the IODATA register.
  - The IODATA register is used as a window to the register or memory address specified by IOADDR register. As a result, the data written to the IODATA register is written into the CSR pointed to by bits 30:0 of the IOADDR register.

3. IOADDR.*Configuration IO Access Enable* is cleared to avoid unintentional CSR read operations (that might cause clear by read) by other applications scanning the configuration space.

Software reads data from an internal CSR via the configuration space in the following manner:

1. CSR address is written to the IOADDR register where:
  - Bit 31 (IOADDR.*Configuration IO Access Enable*) of the IOADDR register should be set to 1b.
  - Bits 30:0 of IOADDR should hold the actual address of the internal register or memory being read.
2. CSR value is read from the IODATA register.
  - The IODATA register is used as a window to the register or memory address specified by the IOADDR register. As a result, the data read from the IODATA register is the data of the CSR pointed to by bits 30:0 of the IOADDR register.
3. IOADDR.*Configuration IO Access Enable* is cleared to avoid un-intentional CSR read operations (that might cause clear by read) by other applications scanning the configuration space.

#### Notes:

- When functioning in a D3 state, software should not attempt to access CSRs via the IOADDR and IODATA configuration registers.
- To enable CSR access via configuration space, software should set bit 31 to 1b (IOADDR.*Configuration IO Access Enable*) in the IOADDR register. Software should clear bit 31 of the IOADDR register after completing CSR access to avoid an unintentional clear-by-read operation by another application scanning the configuration address space.
- Bit 31 of the IOADDR register (IOADDR.*Configuration IO Access Enable*) has no effect when initiating access via I/O address space.
- Configuration access to 0x9C (IODATA) without setting bit 31 of the IOADDR register (IOADDR.*Configuration Access Enable*) must not result in an unsupported request.
- I/O-mapped access and CSR access via PCIe configuration space are mutually exclusive operating modes, and therefore PCIE\_CNF.IO\_SUP NVM bit must be cleared when the PCIE\_CAPSUP.CSR\_CONF\_EN NVM bit is set, and vice versa.

## 8.1.4 Register Terminology

| Type  | Description                                                                                                                                                                              |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RC    | <b>Read Clear</b><br>A register bit with this attribute is cleared after read. Writes have no effect on the bit value.                                                                   |
| RO    | <b>Read Only</b><br>If a register is read only, writes to this register have no effect.                                                                                                  |
| ROS   | <b>Read Only Status</b><br>Writes to ROS fields has no effect. The value of the field can change due to hardware events.                                                                 |
| RSV   | <b>Reserved</b><br>Field can return any value on read access and must be set to its initialized value on write access unless specified differently in the field description.             |
| RW    | <b>Read/Write</b><br>A register with this attribute can be read and written. If written since reset, the value read reflects the value written.                                          |
| RW1C  | <b>Read/Write Clear</b><br>A register with this attribute can be read and written. However, a write of a 1b clears (sets to 0b) the corresponding bit and a write of a 0b has no effect. |
| RW/RC | <b>Read/Write and Read Clear</b>                                                                                                                                                         |
| RWS   | <b>Read Write Set</b><br>Register that is set to 1b by software by writing a 1b to the register, and cleared to 0b by hardware.                                                          |
| WO    | <b>Write Only</b><br>Reading this register might not return a meaningful value.                                                                                                          |

## 8.1.5 VF Registers Allocated per Queue

Depending on configuration, each pool has 2, 4, or 8 queues allocated to it. Note that in IOV mode, any queues not allocated to a VF are allocated to the PF. The registers assigned to a queue are accessible both in its VF address space and in the PF address space. This section describes the address mapping of registers that belong to queues.

[Section 7.8.2.7.2](#) defines the correspondence of queue indices between the PF and the VFs. For example, when in configuration for 32 VFs, queues 124-127 in the PF correspond to queues [3:0] of VF# 31.

**Note:** The queue pair of one VF should be assigned to the PF, therefore the maximum usable number of VFs is 63.

The queues are enumerated in each VF from 0 (i.e. [1:0], [3:0], or [7:0]). If a queue is allocated to a VF, its corresponding registers are accessible in the VF CSR space. Each register is allocated an address in the VF (relative to its base) according to its index in the VF space. Therefore, the registers of queue 0 in each VF are allocated the same addresses, which equal the addresses of the same registers for queue 0 in the PF. For example, RDH[0] in the VF space has the same relative address in each VF and in the PF (address 0x01010).

## 8.1.6 Non-Queue VF Registers

Registers that do not correspond to a specific queue are allocated addresses in the VF space according to these rules:

- Registers that are read-only by the VF (e.g. STATUS) have the same address in the VF space as in the PF space.
- Registers allocated per pool are accessed in the VF in the same location as pool [0] in the PF address space.
- Registers that are RW by the VF (e.g. CTRL) are replicated in the PF, one per VF, in adjacent addresses.

**Note:** Since the VF address space is limited to 16 KB, any register that resides above that address in the PF space cannot reside in the same address in the VF space and is therefore allocated in another location in the VF.

## 8.2 Device Registers - PF

### 8.2.1 BAR0 Registers Summary

**Table 8-4. BAR0 Registers Summary**

| Offset / Alias Offset            | Abbreviation   | Name                                             | Page                |
|----------------------------------|----------------|--------------------------------------------------|---------------------|
| <b>General Control Registers</b> |                |                                                  |                     |
| 0x00000000                       | CTRL           | Device Control Register                          | <a href="#">498</a> |
| 0x00000008                       | STATUS         | Device Status Register                           | <a href="#">499</a> |
| 0x00000018                       | CTRL_EXT       | Extended Device Control Register                 | <a href="#">499</a> |
| 0x00000020                       | ESDP           | Extended SDP Control                             | <a href="#">500</a> |
| 0x00000028                       | PHY_GPIO       | PHY GPIO Register                                | <a href="#">501</a> |
| 0x00000030                       | MAC_GPIO       | MAC GPIO Register                                | <a href="#">502</a> |
| 0x00000100                       | PHYINT_STATUS0 | PHY Interrupt Status Register 0                  | <a href="#">502</a> |
| 0x00000104                       | PHYINT_STATUS1 | PHY Interrupt Status Register 1                  | <a href="#">503</a> |
| 0x00000108                       | PHYINT_STATUS2 | PHY Interrupt Status Register 2                  | <a href="#">504</a> |
| 0x00000200                       | LEDCTL         | LED Control                                      | <a href="#">505</a> |
| 0x00005078                       | EXVET          | Extended VLAN Ether Type - Receive               | <a href="#">506</a> |
| 0x00008224                       | EXVET_T        | Extended VLAN Ether Type - Transmit              | <a href="#">506</a> |

## 8.2.2 Detailed Register Description - PF BAR0

### 8.2.2.1 General Control Registers

#### 8.2.2.1.1 Device Control Register - CTRL (0x00000000)

CTRL is also mapped to address 0x00004 to maintain compatibility with predecessors.

| Field               | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------|--------|-------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RESERVED            | 1:0    | 00b   | RSV  | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| PCIE_MASTER_DISABLE | 2      | 0b    | RW   | <b>PCIe Master Disable</b><br>When set, the device blocks new master requests, including manageability requests, by using this function. Once no master requests are pending by using this function, the <i>PCIE_MASTER_ENABLE_STATUS</i> bit is cleared.<br><b>Note:</b> After any change to this bit, the host must read that the bit has been modified as expected before reading <i>STATUS.PCIE_MASTER_ENABLE_STATUS</i> bit (Section 8.2.2.1.2). |
| LRST                | 3      | 0b    | RW   | <b>Link Reset</b><br>This bit performs a reset of the MAC, PHY, and the entire 10GBase-T Controller (software reset) resulting in a state nearly approximating the state following a power-up reset or internal PCIe reset, except for the system PCI configuration.<br>Normally 0b. Writing 1b initiates the reset.<br>This bit is self-clearing. Also referred to as MAC reset.                                                                     |
| RESERVED            | 25:4   | 0x0   | RSV  | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| RST                 | 26     | 0b    | RW   | <b>Device Reset</b><br>This bit performs a complete reset of the device, resulting in a state nearly approximating the state following a power-up reset or internal PCIe reset, except for the system PCI configuration.<br>Normally 0b. Writing 1b initiates the reset.<br>This bit is self-clearing. Also referred to as a software reset or global reset.                                                                                          |
| RESERVED            | 31:27  | 0x0   | RSV  | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Note:** *LRST* and *RST* can be used to globally reset the entire 10GBase-T Controller. This register is provided primarily as a software mechanism to recover from an indeterminate or suspected hung hardware state. Most registers (receive, transmit, interrupt, statistics, etc.) and state machines are set to their power-on reset values, approximating the state following a power-on or PCI reset. However, PCIe configuration registers are not reset, thereby leaving the device mapped into system memory space and accessible by a software device driver. To ensure that a global device reset has fully completed and that the device responds to subsequent accesses, programmers must wait approximately 1 ms after setting before attempting to check if the bit has cleared, or to access (read or write) any other device register.

### 8.2.2.1.2 Device Status Register - STATUS (0x00000008)

| Field                     | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                 |

#### 8.2.2.1.4 Extended SDP Control - ESDP (0x00000020)

This register is initialized only at LAN\_PWR\_GOOD, preserving the SDP states across software and PCIe resets. Some specific I/O pins are initialized in other resets in native mode as expected for the specific behavior, and described explicitly as follows:

| Field      | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                     |
|------------|--------|-------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SDP0_DATA  | 0      | 0b    | RW   | <b>SDP0 Data Value<sup>1,2</sup></b><br>Used to read (write) a value of the software-controlled I/O pin SDP0.<br>If SDP0 is configured as an output ( <i>SDP0_IODIR</i> = 1b), this bit controls the value driven on the pin. If SDP0 is configured as an input, all reads return the current value of the pin. |
| SDP1_DATA  | 1      | 0b    | RW   | <b>SDP1 Data Value<sup>1,3</sup></b><br>Used to read (write) a value of the software-controlled I/O pin SDP1.<br>If SDP1 is configured as an output ( <i>SDP1_IODIR</i> = 1b), this bit controls the value driven on the pin. If SDP1 is configured as an input, all reads return the current value of the pin. |

1. Initial values are read from the NVM when direction of SDP is Output (*SDPx\_IODIR* = 1).
2. It is assumed that bit 15 of *NC-SI Configuration 2* word in the NVM is cleared. Otherwise, the SDP0 pin of function 0 is used as input pins that encode the NC-SI Package ID of the controller.
3. It is assumed that bit *SDP\_FUNC\_OFF\_EN* of *NVM Control word 2* is cleared. Otherwise, SDP1 pins are strapped during *PE\_RST\_N* to determine that both PCIe functions are disabled.

| AUTO_NEGOTIATION_100BASE_TX_DEVICE_DETECT         | 8      | 0b    | RW   | Reflects the state of PHY register bit 7.EC01.F before it was cleared by a firmware read.         |
| AUTO_NEGOTIATION_ENERGY_ON_LINE_DETECT            | 9      | 0b    | RW   | Reflects the state of PHY register bit 7.EC01.E before it was cleared by a firmware read.         |
| AUTO_NEGOTIATION_NEXT_PAGE_3RD_RECEIVED           | 10     | 0b    | RW   | Reflects the state of PHY register bit 7.EC01.3 before it was cleared by a firmware read.         |
| AUTO_NEGOTIATION_NEXT_PAGE_2ND_RECEIVED           | 11     | 0b    | RW   | Reflects the state of PHY register bit 7.EC01.2 before it was cleared by a firmware read.         |
| AUTO_NEGOTIATION_NEXT_PAGE_1ST_RECEIVED           | 12     | 0b    | RW   | Reflects the state of PHY register bit 7.EC01.1 before it was cleared by a firmware read.         |
| AUTO_NEGOTIATION_BASE_PAGE_RECEIVED               | 13     | 0b    | RW   | Reflects the state of PHY register bit 7.EC01.0 before it was cleared by a firmware read.         |
| AUTO_NEGOTIATION_10BASE_T_DEVICE_DETECT           | 14     | 0b    | RW   | Reflects the inverse state of PHY register bit 7.EC02.2 before it was cleared by a firmware read. |
| AUTO_NEGOTIATION_PROTOCOL_ERROR                   | 15     | 0b    | RW   | Reflects the state of PHY register bit 7.EC01.D before it was cleared by a firmware read.         |
| FLP_IDLE_ERROR                                    | 16     | 0b    | RW   | Reflects the state of PHY register bit 7.EC01.C before it was cleared by a firmware read.         |

| Field                             | Bit(s) | Init. | Type | Description                                                                                 |
|-----------------------------------|--------|-------|------|---------------------------------------------------------------------------------------------|
| AUTO_NEGOTIATION_GBE_PHY_RESERVED | 27:17  | 0x0   | RW   | Reserved. Read as written.                                                                  |
| PCIE_SERDES_LOSS_OF_SIGNAL_3_0    | 31:28  | 0x0   | RW   | Reflects the state of PHY register bit 4.CC02.F:C before it was cleared by a firmware read. |

### 8.2.2.1.9 PHY Interrupt Status Register 2 - PHYINT\_STATUS2 (0x00000108)

Register contents is valid once the corresponding EEMNGCTL.CFG\_DONE0/1 bit is asserted by firmware. Bits are set by firmware to notify the host of the PHY interrupts that were triggered. This register is reset by hardware only at power-up events. The host is responsible to clear the PHY interrupts once it completes the PHY interrupt handling routine.

| Field                             | Bit(s) | Init. | Type | Description                                                                                        |
|-----------------------------------|--------|-------|------|----------------------------------------------------------------------------------------------------|
| GLOBAL_MAC_RESET                  | 0      | 0b    | RW   | Reflects the inverse state of PHY register bit 1E.1200.0 before it was cleared by a firmware read. |
| GLOBAL_MAC_LOW_POWER_LINK_UP_MODE | 1      | 0b    | RW   | Reflects the state of PHY register bit 1E.1204.4 before it was cleared by a firmware read.         |
| GLOBAL_MAC_PHY_DISABLE_MODE       | 2      | 0b    | RW   | Reflects the inverse state of PHY register bit 1E.1204.1 before it was cleared by a firmware read. |
| GLOBAL_MAC_LOW_POWER_MODE         | 3      | 0b    | RW   | Reflects the inverse state of PHY register bit 1E.1204.0 before it was cleared by a firmware read. |
| GLOBAL_MAC_SPI_GRANT              | 4      | 0b    | RW   | Reflects the state of PHY register bit 1E.1206.2 before it was cleared by a firmware read.         |
| GLOBAL_MAC_SPI_CONTROL            | 5      | 0b    | RW   | Reflects the inverse state of PHY register bit 1E.1206.1 before it was cleared by a firmware read. |
| GLOBAL_HIGH_TEMPERATURE_FAILURE   | 6      | 0b    | RW   | Reflects the state of PHY register bit 1E.CC00.E before it was cleared by a firmware read.         |
| GLOBAL_LOW_TEMPERATURE_FAILURE    | 7      | 0b    | RW   | Reflects the state of PHY register bit 1E.CC00.D before it was cleared by a firmware read.         |
| GLOBAL_HIGH_TEMPERATURE_WARNING   | 8      | 0b    | RW   | Reflects the state of PHY register bit 1E.CC00.C before it was cleared by a firmware read.         |
| GLOBAL_LOW_TEMPERATURE_WARNING    | 9      | 0b    | RW   | Reflects the state of PHY register bit 1E.CC00.B before it was cleared by a firmware read.         |
| GLOBAL_RESET_COMPLETED            | 10     | 0b    | RW   | Reflects the state of PHY register bit 1E.CC00.6 before it was cleared by a firmware read.         |
| GLOBAL_DEVICE_FAULT               | 11     | 0b    | RW   | Reflects the state of PHY register bit 1E.CC00.4 before it was cleared by a firmware read.         |
| GLOBAL_PAIR_A_CHANGE_OF_STATUS    | 12     | 0b    | RW   | Reflects the state of PHY register bit 1E.CC00.3 before it was cleared by a firmware read.         |
| GLOBAL_PAIR_B_CHANGE_OF_STATUS    | 13     | 0b    | RW   | Reflects the state of PHY register bit 1E.CC00.2 before it was cleared by a firmware read.         |
| GLOBAL_PAIR_C_CHANGE_OF_STATUS    | 14     | 0b    | RW   | Reflects the state of PHY register bit 1E.CC00.1 before it was cleared by a firmware read.         |
| GLOBAL_PAIR_D_CHANGE_OF_STATUS    | 15     | 0b    | RW   | Reflects the state of PHY register bit 1E.CC00.0 before it was cleared by a firmware read.         |
| GLOBAL_MEDIUM_BER                 | 16     | 0b    | RW   | Reflects the state of PHY register bit 1E.CC01.E before it was cleared by a firmware read.         |
| GLOBAL_RESERVED                   | 31:17  | 0x0   | RW   | Reserved. Read as written.                                                                         |

### 8.2.2.1.10 LED Control - LEDCTL (0x00000200)

**Note:** All init bits in this register are read from the NVM. See [Section 6.4.7.3, “LED Configuration”](#).

| Field             | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                    |
|-------------------|--------|-------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LED0_MODE         | 3:0    | 0x0   | RW   | <b>LED0 Mode</b><br>This field specifies the control source for the LED0 output. An initial value of 0000b selects the LINK_UP indication.                                                                                                                                                     |

### 8.2.2.1.13 Function Active and Power State to Manageability - FACTPS (0x00010150)

Register for use by the device firmware for configuration.

**Note:** In regular mode (port swap disabled - *LAN\_FUNCTION\_SEL* = 0b), the power state indication of port 0 is mapped to the *FUNC0\_POWER\_STATE* field, and the power state indication of port 1 is mapped the *FUNC1\_POWER\_STATE* field. Vice-versa when port swap mode is enabled (*LAN\_FUNCTION\_SEL* = 1b).

| RESERVED            | 31:5   | 0x0   | RSV  | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

### 8.2.2.1.16 SFP I<sup>2</sup>C Command - I2CCMD (0x00015F58)

This register is used by software to read or write to the configuration registers in an SFP module when the *SDP23\_FUNCTION* bit and the *SDP[23]\_NATIVE* bit are set in ESDP register (Section 8.2.2.1.4).

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------|--------|-------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DATA     | 15:0   | X     | RW   | <b>Data</b><br><b>Data in a write command:</b> Software places the data bits and then the MAC shifts them out to the I <sup>2</sup> C bus.<br><b>Data in a read command:</b> The MAC reads these bits serially from the I <sup>2</sup> C bus and then software reads them from this location.<br>This field is interpreted as two consecutive bytes unless the <i>I2CPARAMS.I2C_DATA_ORDER</i> bit is set, in which case the data is considered as a single 16-bit word. When <i>I2CPARAMS.ACCESS_WIDTH</i> = 0b, bits 15:8 are not used. |
| REGADD   | 23:16  | 0x0   | RW   | <b>I<sup>2</sup>C Register Address</b><br>For example, register 0, 1, 2... 255.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

### 8.2.2.1.17 SFP I<sup>2</sup>C Parameters - I2CPARAMS (0x00015F5C)

This register is used to set the parameters for I<sup>2</sup>C access and to allow bit-banging access to the I<sup>2</sup>C interface.

**Note:** This register is reset only on LAN\_PWR\_GOOD.

| Field      | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                           |
|------------|--------|-------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WRITE_TIME | 4:0    | 0x6   | RW   | <b>Write Time</b><br>Defines the delay between a write access and the next access. The value is in milliseconds.<br><b>Note:</b> A value of zero is not valid.                                                                                                                        |
| READ_TIME  | 7:5    | 010b  | RW   | <b>Read Time</b><br>Defines the delay between a read access and the next access. The value is in microseconds.<br><b>Note:</b> A value of zero is not valid.                                                                                                                          |
| I2CBB_EN   | 8      | 0b    | RW   | <b>I<sup>2</sup>C Bit-Bang Enable</b><br>If set, the I2C_CLK and I2C_DATA lines are controlled via the <i>CLK</i> , <i>DATA</i> , and <i>DATA_OE_N</i> bits of this register. Otherwise, they are controlled by hardware once activated via the I2CCMD register (Section 8.2.2.1.16). |
| CLK_OUT    | 9      | 0b    | RW   | <b>I<sup>2</sup>C Clock</b><br>While in bit-bang mode, controls the value driven on the I2C_CLK pad of this port.                                                                                                                                                                     |

| Field           | Bit(s) | Init. | Type | Description                                                                                                                                                                                                  |

#### 8.2.2.2.2 Flash Access Register - FLA (0x0001001C)

**Note:** When NVM is locked, this register is RO to software.

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                            |
|----------|--------|-------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FL_SCK   | 0      | 0b    | RW   | <b>Clock input to the Flash</b><br>When <i>FL_GNT</i> is set to 1b, the <i>FL_SCK</i> output signal is mapped to this bit and provides the serial clock input to the Flash. Software clocks the Flash via toggling this bit with successive writes.                    |
| FL_CE    | 1      | 0b    | RW   | <b>Chip select input to the Flash</b><br>When <i>FL_GNT</i> is set to 1b, the <i>FL_CE</i> output signal is mapped to the chip select of the Flash device. Software enables the Flash by writing a 0b to this bit.                                                     |
| FL_SI    | 2      | 0b    | RW   | <b>Data input to the Flash</b><br>When <i>FL_GNT</i> is set to 1b, the <i>FL_SI</i> output signal is mapped directly to this bit. Software provides data input to the Flash via writes to this bit.                                                                    |
| FL_SO    | 3      | 0b    | ROS  | <b>Data output bit from the Flash</b><br>The <i>FL_SO</i> input signal is mapped directly to this bit in the register and contains the Flash serial data output. This bit is read-only from a software perspective.<br><b>Note:</b> Writes to this bit have no effect. |
| FL_REQ   | 4      | 0b    | RW   | <b>Request Flash Access</b><br>Software must write 1b to this bit to get direct Flash access. It has access when <i>FL_GNT</i> is set to 1b. When software completes the access, it must then write 0b.                                                                |
| FL_GNT   | 5      | 0b    | RO   | <b>Grant Flash Access</b><br>When this bit is set to 1b, software can access the Flash using the <i>FL_SCK</i> , <i>FL_CE</i> , <i>FL_SI</i> , and <i>FL_SO</i> bits.                                                                                                  |
| RESERVED | 6      | 0b    | RO   | Reserved.                                                                                                                                                                                                                                                              |
| JTAG_DIS | 7      | 0b    | RO   | <b>JTAG Disable</b><br>Reflects the value of the <i>JTAG_DIS</i> strap.                                                                                                                                                                                                |

Reads as 0b.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| FL_SADDR | 28:16  | 0x0   | RW   | <b>Flash Sector Erase Address</b><br>Determines which 4 KB sector is erased when the FL_SER command is used. This address is expressed in sector index units, starting from sector index 0.                                                                                                                                                                                                                                            |
| FL_SER   | 29     | 0b    | RW   | <b>Flash Sector Erase Command</b><br>This bit is auto-cleared and reads as 0b. The 4 KB sector index to be erased is determined by the FL_SADDR field.<br><b>Note:</b> The address should fit in the size defined in the FLA.FL_SIZE field.                                                                                                                                                                                            |
| FL_BUSY  | 30     | 0b    | RO   | <b>Flash Busy</b><br>This bit is set to 1b by hardware while Flash access has been granted to a client.<br><b>Note:</b> This bit is read-only from a software perspective.<br><b>Note:</b> This bit only reflect flash busy state if FLA mechanisms, like FL_SER or FL_DER, are used.<br>If the flash is busy due to some action done directly on the SPI pins, it is not reflected in this bit.                                       |
| FL_DER   | 31     | 0b    | RW   | <b>Flash Device Erase Command</b><br>This bit is auto-cleared and reads as 0b. The entire Flash device is erased.                                                                                                                                                                                                                                                                                                                      |

### 8.2.2.2.3 Manageability EEPROM-Mode Control Register - EEMNGCTL (0x00010110)

This register is read/write to manageability firmware, and is read-only to host software. The transactions performed through this register are directed to/from the internal Shadow RAM.

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                     |
|----------|--------|-------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ADDR     | 12:0   | 0x0   | RW   | <b>Address</b><br>This field is written by manageability along with the START and WRITE bits to indicate which NVM word address to read or write. Only the first valid 16 KB is accessible through this EEPROM mode interface dedicated to manageability.                       |
| RESERVED | 14:13  | 00b   | RSV  | Reserved. Reads as 0b.                                                                                                                                                                                                                                                          |
| START    | 15     | 0b    | RW   | <b>Start</b><br>Writing a 1b to this bit causes the device to start the read or write operation of the Shadow RAM according to the write bit. This bit is self cleared by hardware. If one of the CFG_DONE0/1 bit's value is set in this write, writing of this bit is ignored. |
| WRITE    | 16     | 0b    | RW   | <b>Write</b><br>This bit signals the device if the current operation is read or write.<br>0b = Read<br>1b = Write                                                                                                                                                               |
| EEBUSY   | 17     | 0b    | RW   | <b>EEPROM Mode Busy</b><br>This bit indicates that the internal Shadow RAM is busy and should not be accessed.                                                                                                                                                                  |

| Field         | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------|--------|-------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CFG_DONE0     | 18     | 0b    | RW   | <b>Configuration Done Port 0</b><br>Manageability configuration cycle of port 0 completed.<br>This bit indicates that the manageability configuration cycle (configuration of PCIe, core or PHY) completed. This bit is set to 1b by manageability firmware to indicate that the configuration completed and is cleared by software.<br>Writing a 0b by firmware does not affect the state of this bit. Writing a 1b by software does not affect the state of this bit.<br><b>Note:</b> Software should not try to access the PHY for configuration before this bit is set. |
| CFG_DONE1     | 19     | 0b    | RW   | <b>Configuration Done Port 1</b><br>Manageability configuration cycle of port 1 completed.<br>This bit indicates that the manageability configuration cycle (configuration of PCIe, core or PHY) completed. This bit is set to 1b by manageability firmware to indicate that the configuration completed and is cleared by software.<br>Writing a 0b by firmware does not affect the state of this bit. Writing a 1b by software does not affect the state of this bit.<br><b>Note:</b> Software should not try to access the PHY for configuration before this bit is set. |
| TRANS_ABORTED | 20     | 0b    | RO   | <b>Transaction Aborted</b><br>When read as 1b, indicates that the current EEMNGCTL access was aborted due to a firmware reset. The bit is cleared by hardware on the next write access to the EEMNGCTL register, regardless of the written value.                                                                                                                                                                                                                                                                                                                           |
| RESERVED      | 30:21  | 0x0   | RSV  | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| DONE          | 31     | 1b    | RW   | <b>Transaction Done</b><br>This bit is cleared when the <i>START</i> and <i>WRITE</i> bits are set by manageability, and is set back again when the Shadow RAM write or read transaction completes.                                                                                                                                                                                                                                                                                                                                                                         |

#### 8.2.2.2.4 Manageability EEPROM-Mode Read/Write Data - EEMNGDATA (0x00010114)

This register is read/write to manageability firmware, and is read-only to host software.

| Field  | Bit(s) | Init. | Type | Description                                                                                       |
|--------|--------|-------|------|---------------------------------------------------------------------------------------------------|
| WRDATA | 15:0   | 0x0   | RW   | <b>Write Data</b><br>Data to be written to the Shadow RAM.                                        |
| RDDATA | 31:16  | X     | RW   | <b>Read Data</b><br>Data returned from the read command.<br><b>Note:</b> This field is read only. |

### 8.2.2.2.5 Manageability Flash Control Register - FLMNGCTL (0x00010118)

This register is read/write to manageability firmware, and is read-only to host software.

| Field      | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                      |
|------------|--------|-------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ADDR       | 23:0   | 0x0   | RW   | <b>Address</b><br>This field is written by manageability along with <i>CMD</i> and <i>CMDV</i> to indicate which Flash address to read or write. For the Sector Erase command ( <i>CMD</i> = 10b), it must point to any address in the 4 KB sector to be erased.                 |
| CMD        | 25:24  | 00b   | RW   | <b>Command</b><br>Indicates which command should be executed. Valid only when the <i>CMDV</i> bit is set.<br>00b = Read<br>01b = Write (single byte)<br>10b = Sector Erase — The ADDR field determines the 4 KB sector index to be erased by this command.<br>11b = Device Erase |
| CMDV       | 26     | 0b    | RW   | <b>Command Valid</b><br>When set, indicates that the manageability firmware issues a new command and is cleared by hardware at the end of the command.                                                                                                                           |
| FLBUSY     | 27     | 0b    | RW   | <b>Flash Busy</b><br>This bit indicates that the Flash is busy processing a Flash transaction and should not be accessed.                                                                                                                                                        |
| RESERVED   | 29:28  | 00b   | RSV  | Reserved.                                                                                                                                                                                                                                                                        |
| DATA_VALID | 30     | 0b    | RW   | <b>Read Done</b><br>Read done and data in FLMNGDATA is valid.<br>This bit is cleared by firmware when it sets the <i>CMDV</i> bit. It is set by hardware for each Dword read that completes. This bit is read/clear by hardware enabling the multiple Dword read flow.           |
| GLDONE     | 31     | 1b    | RW   | <b>Global Done</b><br>This bit clears after the <i>CMDV</i> bit is set by manageability, and is set back again when all Flash transactions complete. For example, the Flash device finished reading all the requested read or other accesses (write and erase).                  |

### 8.2.2.2.6 Manageability Flash Read/Write Data - FLMNGDATA (0x0001011C)

This register is read/write to manageability firmware, and is read-only to host software.

| Field | Bit(s) | Init. | Type | Description                                                                                                                                                                   |
|-------|--------|-------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DATA  | 31:0   | 0x0   | RW   | <b>Data</b><br>Read/Write data on a read transaction. This register contains the data returned from the Flash read. On write transactions, bits 7:0 are written to the Flash. |

### 8.2.2.2.7 JEDEC ID 1 - JEDEC\_ID\_1 (0x00015F2C)

Exposes the JEDEC ID of the connected flash. Reflects an internal auxiliary register.

**Note:** This register is valid only if a valid firmware is present.

| Field           | Bit(s) | Init. | Type | Description                                                                                                        |
|-----------------|--------|-------|------|--------------------------------------------------------------------------------------------------------------------|
| BANK            | 6:0    | 0x0   | ROS  | <b>Bank</b><br>Defines the bank number of the manufacturer ID (number of 0x7F read).                               |
| VALID           | 7      | 0b    | ROS  | <b>Valid</b><br>When this bit is set, the firmware stored a valid content to this register.                        |
| MANUFACTURER_ID | 15:8   | 0x0   | ROS  | <b>Manufacturer ID</b><br>Returns the manufacturer ID read by RDID command.                                        |
| DEVICE_ID_1     | 23:16  | 0x0   | ROS  | <b>Device ID 1</b><br>First byte of the device ID read by RDID command ( <i>Family</i> and <i>Density</i> fields). |
| DEVICE_ID_2     | 31:24  | 0x0   | ROS  | <b>Device ID 2</b><br>Second Byte of the device ID read by RDID command (Sub version and Revision).                |

## 8.2.2.3 Flow Control Registers

### 8.2.2.3.1 Flow Control Transmit Timer Value n - FCTTVN[n] (0x00003200 + 0x4\*n, n=0...3)

Each 32-bit register (n=0...3) refers to two timer values (register 0 refers to timer 0 and 1; register 1 refers to timer 2 and 3, etc.).

**Note:** The 16-bit value in the *TTV* field is inserted into a transmitted frame (either XOFF frames or any pause frame value in any software transmitted packets). It counts in units of slot time (usually 64 bytes). The device uses a fixed slot time value of 64-byte times.

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                         |
|----------|--------|-------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TTV_2N   | 15:0   | 0x0   | RW   | <b>Transmit Timer Value 2n</b><br>Timer value included in XOFF frames as Timer (2n). The same value must be set to User Priorities (UPs) attached to the same TC, as defined in the RTTUP2TC register. For legacy 802.3X flow control packets, TTV0 is the only timer that is used. |
| TTV_2N_1 | 31:16  | 0x0   | RW   | <b>Transmit Timer Value 2n+1</b><br>Timer value included in XOFF frames as Timer 2n+1. The same value must be set to UPs attached to the same TC, as defined in the RTTUP2TC register.                                                                                              |

### 8.2.2.3.2 Flow Control Receive Threshold Low - FCRTL[n] (0x00003220 + 0x4\*n, n=0...7)

This register contains the receive threshold used to determine when to send an XON packet, and counts in units of bytes. The lower four bits must be programmed to 0x0 (16-byte granularity). Software must set *XONE* to enable the transmission of XON frames. Each time incoming packets cross the receive high threshold (become more full), and then crosses the receive low threshold, with *XONE* enabled (1b), hardware transmits an XON frame.

**Note:** Each 32-bit register (n=0...7) refers to a different receive packet buffer.

| Field    | Bit(s) | Init. | Type | Description                                                                                                                        |
|----------|--------|-------|------|------------------------------------------------------------------------------------------------------------------------------------|

### 8.2.2.3.3 Flow Control Receive Threshold High - FCRTH[n] (0x00003260 + 0x4\*n, n=0...7)

This register contains the receive threshold used to determine when to send an XOFF packet and counts in units of bytes. This value must be at least eight bytes less than the maximum number of bytes allocated to the receive packet buffer and the lower five bits must be programmed to 0x0 (32-byte granularity). Each time the receive FIFO reaches the fullness indicated by *RTH*, hardware transmits a pause frame if the transmission of flow control frames is enabled.

**Note:** Each 32-bit register (n=0... 7) refers to a different receive packet buffer.

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                            |

### 8.2.2.3.7 Priority Flow Control Type Opcode - PFCTOP (0x0000431C)

This register contains the *Type* and *Opcode* fields that are matched against a recognized priority flow control packet.

| Field | Bit(s) | Init.  | Type | Description                                                                                                |
|-------|--------|--------|------|------------------------------------------------------------------------------------------------------------|
| FCT   | 15:0   | 0x8808 | RW   | <b>Priority Flow Control EtherType</b><br>This field appears in little endian (MS byte first on the wire). |
| FCOP  | 31:16  | 0x0101 | RW   | <b>Priority Flow Control Opcode</b><br>This field appears in big endian (LS byte first on the wire).       |

### 8.2.2.3.8 Transmit Flow Control Status - TFCS (0x0000CE00)

| Field    | Bit(s) | Init. | Type | Description                             |
|----------|--------|-------|------|-----------------------------------------|
| TC_XON   | 7:0    | 0xFF  | RO   | <b>TC XON</b><br>TC is in FC XON state. |
| RESERVED | 31:8   | 0x0   | RSV  | Reserved.                               |

## 8.2.2.4 PCIe Registers

This section contains the registers used to control the PCIe core behavior.

### 8.2.2.4.1 PCIe Function Status 1 - PCI\_STATUS1 (0x00011028)

| Field      | Bit(s) | Init. | Type | Description                                                                                                                                                     |
|------------|--------|-------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FUNC_VALID | 0      | 0b    | RO   | <b>Function Valid</b><br>0b - Function is disabled<br>1b - Function is enabled<br><b>Note:</b> This bit is valid to firmware even when the function is disabled |
| RESERVED   | 31:1   | 0x0   | RSV  | Reserved.                                                                                                                                                       |

### 8.2.2.4.2 PCIe Firmware Control - PCI\_FWCTRL (0x00011040)

| Field       | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------|--------|-------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TCO_ISOLATE | 0      | 0b    | RW   | <b>TCO Isolate</b><br>Set to 1b on a TCO Reset SMBus or NC-SI OEM command, when the <i>TCO_ISOLATE</i> bit is set.<br>Host write cycles are completed successfully on the PCIe, but silently ignored by internal logic.<br><b>Note:</b> When firmware initiates the TCO Isolate command, it also writes a value of 0x03 to the <i>FWSM.EXT_ERR_IND</i> field.<br>This bit is RO and mirrors the value of the <i>Isolate</i> bit in the internal management registers.<br><b>Note:</b><br>1. Bit is reset by LAN_PWR_GOOD and firmware reset only.<br>2. Bit reflects internal management register <i>Aux</i> bit. |
| RESERVED    | 31:1   | 0x0   | RSV  | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

### 8.2.2.4.3 PCIe CSR Access Timeout - PCI\_CSRT0 (0x00011044)

| Field   | Bit(s) | Init.  | Type | Description                                                                                |
|---------|--------|--------|------|--------------------------------------------------------------------------------------------|
| CSR_TO  | 15:0   | 0x000F | RW   | <b>CSR Timeout</b><br>Defines the timeout value in micro second for CSR accesses           |
| MSIX_TO | 31:16  | 0x0028 | RW   | <b>MSI-X Timeout</b><br>Defines the timeout value in micro second for MSI-X table accesses |

### 8.2.2.4.4 PCIe Control Extended Register - GCR\_EXT (0x00011050)

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                              |
|----------|--------|-------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VT_MODE  | 1:0    | 00b   | RW   | <b>VT Mode of operation</b><br>Defines the allocation of physical registers to the VFs. Software must set this field the same as GPIE.<br>VT_Mode:<br>00b = noVT — Reserved for the case that <i>STATUS.IOV_ENA</i> is not set.<br>01b = VT16 — Resources are allocated to 16 VFs.<br>10b = VT32 — Resources are allocated to 32 VFs.<br>11b = VT64 — Resources are allocated to 64 VFs. |
| RESERVED | 3:2    | 00b   | RSV  | Reserved.                                                                                                                                                                                                                                                                                                                                                                                |

#### 8.2.2.4.19 PCIe Statistic Control Registers #2 - PCI\_GSCL\_2 (0x0001804)

This register defines the events counted by the performance counters.

| Field           | Bit(s) | Init. | Type | Description                                                               |
|-----------------|--------|-------|------|---------------------------------------------------------------------------|
| GIO_EVENT_NUM_0 | 7:0    | 0x0   | RW   | <b>GIO Event Number 0</b><br>Event number that counter 0 counts (GSCN_0). |
| GIO_EVENT_NUM_1 | 15:8   | 0x0   | RW   | <b>GIO Event Number 1</b><br>Event number that counter 1 counts (GSCN_1). |
| GIO_EVENT_NUM_2 | 23:16  | 0x0   | RW   | <b>GIO Event Number 2</b><br>Event number that counter 2 counts (GSCN_2). |
| GIO_EVENT_NUM_3 | 31:24  | 0x0   | RW   | <b>GIO Event Number 3</b><br>Event number that counter 3 counts (GSCN_3). |

#### 8.2.2.4.20 PCIe Statistic Control Register #5...#8 - PCI\_GSCL\_5\_8[n] (0x00011810 + 0x4\*n, n=0...3)

These registers control the operation of the leaky bucket counter n.

GSCL\_5 corresponds to n=0.

GSCL\_6 corresponds to n=1.

GSCL\_7 corresponds to n=2.

GSCL\_8 corresponds to n=3.

| Field           | Bit(s) | Init. | Type | Description                                                                                                                                                  |
|-----------------|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LBC_THRESHOLD_N | 15:0   | 0x0   | RW   | <b>Leaky Bucket Counter Threshold n</b><br>Threshold for the Leaky Bucket Counter n.                                                                         |
| LBC_TIMER_N     | 31:16  | 0x0   | RW   | <b>Leaky Bucket Counter Timer n</b><br>Time period between decrementing the value in Leaky Bucket Counter n.<br>The time period is defined in $\mu$ s units. |

#### 8.2.2.4.21 PCIe Statistic Counter Registers #0...#3 - PCI\_GSCN\_0\_3[n] (0x00011820 + 0x4\*n, n=0...3)

These registers contain the performance counters 0-3.

GSCL\_0 corresponds to n=0.

GSCL\_1 corresponds to n=1.

GSCL\_2 corresponds to n=2.

GSCL\_3 corresponds to n=3.

| Field         | Bit(s) | Init. | Type | Description                                                                                                                                                   |
|---------------|--------|-------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EVENT_COUNTER | 31:0   | 0x0   | RO   | <b>Event Counter</b><br>Event counter as defined in PCI_GSCL_2.GIO_EVENT_NUM_[0...3] fields.<br>These registers are stuck at their maximum value of 0xFF...F. |

## 8.2.2.5 PCIe Configuration Space Setting Registers

This section contains registers used to set the default setting of the PCIe configuration space. These registers are reset and loaded from the NVM at PCIe reset.

### 8.2.2.5.1 PCIe PF Configuration - PCI\_CNF (0x00011000)

Contains the per-PF configuration loaded from the NVM.

| Field     | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                           |
|-----------|--------|-------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RESERVED  | 2:0    | 000b  | RW   | Reserved.                                                                                                                                                                                                                                                                                                                             |

### 8.2.2.5.2 PCIe PF Device ID - PCI\_PFDEVID (0x00011008)

Contains the per-PF Device ID.

| Field         | Bit(s) | Init.  | Type | Description                                                                                                        |
|---------------|--------|--------|------|--------------------------------------------------------------------------------------------------------------------|
| PF_DEV_ID_LAN | 15:0   | 0x1562 | RW   | <b>PF Device ID LAN</b><br>Contains the Device ID for this PF when the function has an Ethernet device Class Code. |
| PF_DEV_ID_SAN | 31:16  | 0x1562 | RW   | <b>PF Device ID SAN</b><br>Contains the Device ID for this PF when the function has a SCSI device Class Code.      |

### 8.2.2.5.3 PCIe VF Device ID - PCI\_VFDEVID (0x00011010)

Contains the per-PF Device IDs for its VFs.

| Field         | Bit(s) | Init.  | Type | Description                                                                                                              |
|---------------|--------|--------|------|--------------------------------------------------------------------------------------------------------------------------|
| VF_DEV_ID_LAN | 15:0   | 0x1565 | RW   | <b>VF Device ID LAN</b><br>Contains the device ID for this PF's VFs when the function has an Ethernet device class code. |
| VF_DEV_ID_SAN | 31:16  | 0x1565 | RW   | <b>VF Device ID SAN</b><br>Contains the device ID for this PF's VFs when the function has a SCSI device class code.      |

#### 8.2.2.5.4 PCIe Storage Class - PCI\_CLASS (0x00011038)

Contains the per-PF configuration loaded from the NVM.

| Field         | Bit(s) | Init. | Type | Description                                                                                                                                       |
|---------------|--------|-------|------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| STORAGE_CLASS | 0      | 0b    | RW   | <b>Storage Class</b><br>0b = The class code of this port is set to 0x020000 (LAN).<br>1b = The class code of this port is set to 0x010000 (SCSI). |
| RESERVED      | 31:1   | 0x0   | RSV  | Reserved.                                                                                                                                         |

#### 8.2.2.5.5 PCIe Vendor ID - PCI\_VENDORID (0x0001103C)

The Vendor ID exposed in config space. A value of 0xFFFF is not loaded to configuration space. Shared for all PFs.

| Field     | Bit(s) | Init.  | Type | Description                                                                                                                                 |
|-----------|--------|--------|------|---------------------------------------------------------------------------------------------------------------------------------------------|
| VENDOR_ID | 15:0   | 0x8086 | RW   | <b>Vendor ID</b><br>Contains the Vendor ID exposed in offset 0x0 in the configuration space of all functions. A value of 0xFFFF is ignored. |
| RESERVED  | 31:16  | 0x0    | RSV  | Reserved.                                                                                                                                   |

#### 8.2.2.5.6 PCI BAR Control - PCI\_LBARCTRL (0x00011048)

| Field       | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                     |

#### 8.2.2.5.16 PCIe Upper Address - PCI\_UPADD (0x000110E8)

This register is used to block PCIe master accesses above some address.

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                  |
|----------|--------|-------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RESERVED | 0      | 0b    | RSV  | Reserved.                                                                                                                                                                                                                                                                    |
| ADDRESS  | 31:1   | 0x0   | RW   | <b>Address</b><br>Bits[31:1] correspond to Bits[63:33] in the PCIe address space, respectively.<br>Bits that should not be set in the addresses on the PCIe should be set in this field. For example in a 48-bit architecture, the value of this field should be 0xFFFF0000. |

#### 8.2.2.5.17 PCIe Serial Number MAC Address Low - PCI\_SERL (0x000110F0)

| Field     | Bit(s) | Init. | Type | Description                                                                                                 |
|-----------|--------|-------|------|-------------------------------------------------------------------------------------------------------------|
| SER_NUM_L | 31:0   | 0x0   | RW   | <b>Serial Number Low</b><br>The low DW of the Ethernet MAC Address used to generate the PCIe serial number. |

### 8.2.2.5.18 PCIe Global Config 2 - PCI\_CNFG2 (0x000110F8)

This register contains global status fields of the PCIe configuration.

| Field          | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                |
|----------------|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RESERVED       | 0      | 0b    | RSV  | Reserved.                                                                                                                                                                                                                                                                                  |
| CACHELINE_SIZE | 1      | 0b    | RW   | <b>Cache Line Size</b><br>Determines the system cache line size<br>0b = 64 B<br>1b = 128 B<br>This field is loaded from NVM.                                                                                                                                                               |
| MSI_X_PF_N     | 12:2   | 0x3F  | RW   | <b>MSI_X PF Table Size</b><br>System software reads this field to determine the MSI-X Table Size N, which is encoded as N-1.<br>This field is loaded from the NVM <i>MSI_X_N_PF</i> field, and reflects the same field in the PCIe MSI-X configuration (Message Control Register)          |
| MSI_X_VF_N     | 23:13  | 0x02  | RW   | <b>MSI_X VF Table Size</b><br>System software reads this field to determine the MSI-X Table Size N for VFs, which is encoded as N-1.<br>This field is loaded from the NVM <i>MSI_X_N_VF</i> field and reflects the same field in the PCIe MSI-X configuration (VF MSI-X Control Register). |
| NUM_VFS        | 31:24  | 0x40  | RW   | <b>Number of VFs</b><br>The number of VFs requested by the function. Valid values are 0 - 64. If value is zero, SR-IOV capability is hidden.                                                                                                                                               |

## 8.2.2.6 Interrupt Registers

### 8.2.2.6.1 Extended Interrupt Cause Register - EICR (0x00000800)

The EICR register is RW1C and can be optionally cleared on a read depending on the ODC flag setting in the GPIE register (Section 8.2.2.6.9).

| Field         | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------|--------|-------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RTXQ          | 15:0   | 0x0   | RW1C | <b>Receive/Transmit Queue Interrupts</b><br>One bit per queue or a bundle of queues, activated on receive/transmit events. The mapping of queue to the RTXQ bits is done by the IVAR registers.                                                                                                                                                                                                                                                                                                                                         |
| FLOW_DIRECTOR | 16     | 0b    | RW1C | <b>Flow Director</b><br>Flow director exception is activated by one of the following events: <ul style="list-style-type: none"><li>Filter removal failed (there was no matched filter to be removed).</li><li>The number of remaining free filters in the flexible filter table exceeds (goes below) the FDIRCTRL.FULL_THRESH (Section 8.2.2.15.1).</li><li>Filter programming failed due to no space in the flow director table. Note that this case should not happen if the driver handles the FDIRCTRL.FULL_THRESH event.</li></ul> |
| RX_MISS       | 17     | 0b    | RW1C | <b>Rx Miss</b><br>Missed packet interrupt is activated for each received packet that overflows the Rx packet buffer (overrun).                                                                                                                                                                                                                                                                                                                                                                                                          |
| PCI_EXCEPTION | 18     | 0b    | RW1C | <b>PCI Exception</b><br>The PCI exception is activated by one of the events described in Section 3.1.5.8, "Proprietary Error Reporting"<br>The specific PCI event is error reported in the PCI_ICAUSE register (Section 8.2.2.4.9).                                                                                                                                                                                                                                                                                                     |
| MAILBOX       | 19     | 0b    | RW1C | <b>Mailbox</b><br>VF to PF mailbox interrupt. Caused by a VF write access to the PF mailbox or by a malicious event detection                                                                                                                                                                                                                                                                                                                                                                                                           |
| LSC           | 20     | 0b    | RW1C | <b>Link Status Change</b><br>This bit is set each time the link status changes (either from up-to-down, or from down-to-up).                                                                                                                                                                                                                                                                                                                                                                                                            |
| LINKSEC       | 21     | 0b    | RW1C | <b>LinkSec</b><br>Indicates that the Tx LinkSec packet counter reached the threshold requiring key exchange.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| MNG           | 22     | 0b    | RW1C | <b>Manageability Event Detected</b><br>Indicates that a manageability event occurred.<br>When the device is in power-down mode, the BMC might generate a PME for the same events that would cause an interrupt when the device is at the D0 state.<br>This interrupt bit is also used to alert the host when the BMC IP Address was changed or when EEMNGCTL.CFG_DONE0/1 bit is set by firmware (see Section 3.7.3.4.5).<br>It is also used to indicate ECC events in the embedded management controller memories.                      |
| TS            | 23     | 0b    | RW1C | <b>Thermal Sensor event</b><br>Indicates that a thermal sensor trip point was crossed.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| TIMESYNC      | 24     | 0b    | RW1C | <b>TimeSync Interrupt</b><br>Indicates that a Time Sync event has occurred. | EIAME         | 30     | 0b    | RW   | <b>Extended Interrupt Auto Mask Enable</b><br>When set, the EIMS register can be auto-cleared (depending on EIAM setting) upon interrupt assertion. In any case, the EIMS register can be auto-cleared (depending on EIAM setting) following a write-to-clear (or read) to the EICR register.<br>Software might set the EIAME bit only in MSI-X mode. |
| PBA_SUPPORT   | 31     | 0b    | RW   | <b>PBA Support</b><br>When set, setting one of the extended interrupts masks via EIMS causes the PBA bit of the associated MSI-X vector to be cleared. Otherwise, the device behaves in a way supporting legacy INT-x interrupts.<br><b>Note:</b> Should be cleared when working in INT-x or MSI mode and set in MSI-X mode.                          |

### 8.2.2.6.10 Interrupt Vector Allocation Registers - IVAR[n] (0x00000900 + 0x4\*n, n=0...63)

These registers map interrupt causes into EICR entries (legacy/MSI modes) or into MSI-X vectors (MSI-X modes). See Section 7.3.4 for mapping and use of these registers. Transmit and receive queues mapping to IVAR registers is shown here:

| Field           | Bit(s) | Init. | Type | Description                                                                                           |
|-----------------|--------|-------|------|-------------------------------------------------------------------------------------------------------|
| INT_ALLOC_0     | 5:0    | X     | RW   | <b>Interrupt Allocation 0</b><br>The interrupt allocation for Rx queue ('2xN' for IVAR register 'N'). |
| RESERVED        | 6      | 0b    | RSV  | Reserved.                                                                                             |
| INT_ALLOC_VAL_0 | 7      | 0b    | RW   | <b>Interrupt Allocation Valid 0</b><br>Interrupt allocation valid indication for INT_ALLOC[0].        |

### 8.2.2.6.11 Miscellaneous Interrupt Vector Allocation - IVAR\_MISC (0x00000A00)

These register maps interrupt causes into MSI-X vectors (MSI-X modes). See [Section 7.3.4](#) for mapping and use of these registers.

**Note:** The *INT\_ALLOC\_VAL\_1* bit default value is 1b to enable legacy driver functionality.

| Field           | Bit(s) | Init. | Type | Description                                                                                                                                  |
|-----------------|--------|-------|------|----------------------------------------------------------------------------------------------------------------------------------------------|
| INT_ALLOC_0     | 6:0    | X     | RW   | <b>Interrupt Allocation 0</b><br>Defines the MSI-X vector assigned to the TCP timer interrupt cause.<br>The value must be in the 0-63 range. |
| INT_ALLOC_VAL_0 | 7      | 0b    | RW   | <b>Interrupt Allocation Valid 0</b><br>Valid bit for <i>INT_ALLOC</i> [0].                                                                   |
| INT_ALLOC_1     | 14:8   | X     | RW   | <b>Interrupt Allocation 1</b><br>Defines the MSI-X vector assigned to the "Other" interrupt cause.<br>The value must be in the 0-63 range.   |
| INT_ALLOC_VAL_1 | 15     | 1b    | RW   | <b>Interrupt Allocation Valid 1</b><br>Valid bit for <i>INT_ALLOC</i> [1].                                                                   |
| RESERVED        | 31:16  | 0x0   | RSV  | Reserved.                                                                                                                                    |

### 8.2.2.6.12 Extended Interrupt Cause Set Registers 1 - EICS1 (0x00000A90)

| Field               | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                             |
|---------------------|--------|-------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INTERRUPT_CAUSE_SET | 31:0   | 0x0   | WO   | <b>Interrupt Cause Set</b><br>Setting any bit in this register sets its corresponding bit in the <i>EICR</i> [n] register, and generates an interrupt if enabled by the <i>EIMS</i> [n] register.<br>Reading this register provides no meaningful data. |

### 8.2.2.6.13 Extended Interrupt Cause Set Registers 2 - EICS2 (0x00000A94)

| Field               | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                          |
|---------------------|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INTERRUPT_CAUSE_SET | 31:0   | 0x0   | WO   | <b>Interrupt Cause Set</b><br>Setting any bit in this register sets its corresponding bit in the EICR[n] register, and generates an interrupt if enabled by the EIMS[n] register. Reading this register provides no meaningful data. |

### 8.2.2.6.14 Extended Interrupt Mask Set/Read Registers - EIMS1 (0x00000AA0)

| Field            | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                     |
|------------------|--------|-------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INTERRUPT_ENABLE | 31:0   | 0x0   | RWS  | <b>Interrupt Enable</b><br>Each bit at 1b enables its corresponding interrupt in the EICR[n] register. Writing 1b to any bit sets it. Writing 0b has no impact. Reading this register provides a map of those interrupts that are enabled. Bits[15:0] of EIMS1 are mirrored in EIMS Bits[15:0]. |

### 8.2.2.6.15 Extended Interrupt Mask Set/Read Registers - EIMS2 (0x00000AA4)

| Field            | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                     |
|------------------|--------|-------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INTERRUPT_ENABLE | 31:0   | 0x0   | RWS  | <b>Interrupt Enable</b><br>Each bit at 1b enables its corresponding interrupt in the EICR[n] register. Writing 1b to any bit sets it. Writing 0b has no impact. Reading this register provides a map of those interrupts that are enabled. Bits[15:0] of EIMS1 are mirrored in EIMS Bits[15:0]. |

### 8.2.2.6.16 Extended Interrupt Mask Clear Registers 1 - EIMC1 (0x00000AB0)

| Field          | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                      |
|----------------|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INTERRUPT_MASK | 31:0   | 0x0   | WO   | <b>Interrupt Mask</b><br>Writing 1b to any bit clears its corresponding bit in the EIMS[n] register, disabling the corresponding interrupt in the EICR[n] register. Writing 0b has no impact. Reading this register provides no meaningful data. |

### 8.2.2.6.17 Extended Interrupt Mask Clear Registers 2 - EIMC2 (0x00000AB4)

| Field          | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                      |
|----------------|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INTERRUPT_MASK | 31:0   | 0x0   | WO   | <b>Interrupt Mask</b><br>Writing 1b to any bit clears its corresponding bit in the EIMS[n] register, disabling the corresponding interrupt in the EICR[n] register. Writing 0b has no impact. Reading this register provides no meaningful data. |

### 8.2.2.6.18 Extended Interrupt Auto Mask Enable Registers 1 - EIAM1 (0x0000AD0)

| Field     | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                            |
|-----------|--------|-------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AUTO_MASK | 31:0   | 0x0   | RW   | <b>Auto-Mask</b><br>At 1b, each bit enables auto-set and auto-clear of its corresponding bits in the EIMS[n] register. Bits[15:0] of EIAM1 are mirrored in EIAM Bits[15:0].<br><b>Note:</b> If any of the <i>AUTO_MASK</i> enable bits is set, the GPIE.EIAME bit must be set as well. |

### 8.2.2.6.19 Extended Interrupt Auto Mask Enable Registers 2 - EIAM2 (0x0000AD4)

| Field     | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                            |
|-----------|--------|-------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AUTO_MASK | 31:0   | 0x0   | RW   | <b>Auto-Mask</b><br>At 1b, each bit enables auto-set and auto-clear of its corresponding bits in the EIMS[n] register. Bits[15:0] of EIAM1 are mirrored in EIAM Bits[15:0].<br><b>Note:</b> If any of the <i>AUTO_MASK</i> enable bits is set, the GPIE.EIAME bit must be set as well. |

### 8.2.2.6.20 RSC Enable Interrupt - RSCINT[n] (0x00012000 + 0x4\*n, n=0...128)

| Field    | Bit(s) | Init. | Type | Description                                                                                         |
|----------|--------|-------|------|-----------------------------------------------------------------------------------------------------|
| RSCEN    | 0      | 1b    | RW   | <b>RSC Enable</b><br>This bit enables RSC on the receive queues associated with interrupt vector n. |
| RESERVED | 31:1   | 0x0   | RSV  | Reserved.                                                                                           |

### 8.2.2.7 MSI-X Table Registers

The MSI-X capability is described in [Section 9.2.3.3](#). The MSI-X table is described in [Section 9.2.3.3.4](#), and the Pending Bit Array (PBA) is described in [Section 9.2.3.3.5](#). These registers are located in the MSI-X BAR.

#### 8.2.2.7.1 MSI-X PBA Clear - PBACL[n] (0x000110C0 + 0x4\*n, n=0...7)

**Note:** PBACL[0] is also mapped to address 0x11068 to maintain compatibility with previous products.

| Field     | Bit(s) | Init. | Type | Description                                                                                                                                                       |
|-----------|--------|-------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PENBITCLR | 31:0   | 0x0   | RW   | <b>MSI-X Pending Bits Clear</b><br>Writing 1b to any bit clears it's content. Writing 0b has no effect.<br>Reading this register returns the MSIPBA.PENBIT value. |

#### 8.2.2.7.2 VF MSI-X PBA Clear - VFPBACL[n] (0x000110C8 + 0x4\*n, n=0...5)

These registers reflect the VFPBACL bits of the VFs. This PBA is a vector of 192 bits. The vector starts at Bit[31] of register p=5 and ends at Bit[0] of register p=0 ("reverse" ordering). Each VF has 3 bits in this vector while, PENBIT[2:0] of VF=vi are mapped to bits vi \* 3... vi \* 3 + 2. Explicitly, PENBIT[2] of VF0 is at Bit[31] of register p=5, and so on.

| Field     | Bit(s) | Init. | Type | Description                                                                                                                                                       |
|-----------|--------|-------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PENBITCLR | 31:0   | 0x0   | RW   | <b>MSI-X Pending Bits Clear</b><br>Writing 1b to any bit clears it's content. Writing 0b has no effect.<br>Reading this register returns the MSIPBA.PENBIT value. |

## 8.2.2.8 Receive Registers

### 8.2.2.8.1 Receive Checksum Control - RXCSUM (0x00005000)

This register controls the receive checksum off-loading features of the X550.

**Note:** This register should only be initialized (written) when the receiver is not enabled. For example, only write this register when `RXCTRL.RXEN = 0` (Section 8.2.2.9.11).

### 8.2.2.8.4 Filter Control Register - FCTRL (0x00005080)

**Note:** Before receive filters are updated/modified, the RXCTRL.RXEN bit should be set to 0b (refer to [Section 8.2.2.9.11](#)). Once the proper filters are set, the RXCTRL.RXEN bit can be set to 1b to re-enable the receiver. In FCoE mode, DDP contexts should be invalidated before clearing RXCTRL.RXEN bit.

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

### 8.2.2.8.9 Multicast Table Array - MTA[n] (0x00005200 + 0x4\*n, n=0...127)

This table should be initialized by software before transmit and receive are enabled.

| Field      | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------|--------|-------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BIT_VECTOR | 31:0   | X     | RW   | <b>Bit Vector</b><br>Word wide bit vector specifying 32 bits in the multicast address filter table.<br>This device provides multicast filtering for 4096 multicast addresses by providing single bit entry per multicast address. Those 4096 address locations organized in a Multicast Table Array (128 registers of 32 bits each).<br>Only 12 bits out of the 48-bit destination address are considered as multicast address. Those 12 bits can be selected by <i>MO</i> field of MCSTCTRL register (Section 8.2.2.8.7).<br>The 7 MS bits of the Ethernet MAC Address (out of the 12 bits) selects the register index, while the 5 LS bits (out of the 12 bits) selects the bit within a register. |

### 8.2.2.8.10 Receive Address Low - RAL\_ALIAS[n] (0x00005400 + 0x8\*n, n=0...15; RW)

These registers are aliases to the first 16 RAL addresses.

Field definitions are the same as those defined in Section 8.2.2.8.14

### 8.2.2.8.11 Receive Address High - RAH\_ALIAS[n] (0x00005404 + 0x8\*n, n=0...15; RW)

These registers are aliases to the first 16 RAH addresses.

Field definitions are the same as those defined in Section 8.2.2.8.15

### 8.2.2.8.12 Multiple Receive Queues Command Register - MRQC\_ALIAS (0x00005818; RW)

This is an alias to the MRQC register.

Field definitions are the same as those defined in Section 8.2.2.8.23

### 8.2.2.8.13 VLAN Filter Table Array - VFTA[n] (0x0000A000 + 0x4\*n, n=0...127)

This table should be initialized by software before transmit and receive are enabled.

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                        |
|----------|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VLAN_FLT | 31:0   | X     | RW   | <b>VLAN Filter</b><br>Each bit 'i' in register 'n' affects packets with VLAN VID equal to 32*n+i. 128 VLAN Filter registers compose a table of 4096 bits that cover all possible VLANs.<br>Each bit when set, allows packets with the associated VID to pass. Each bit when cleared, blocks packets with this VID. |

#### 8.2.2.8.14 Receive Address Low - RAL[n] (0x0000A200 + 0x8\*n, n=0...127)

These registers contain the lower 32 bits of the 48-bit Ethernet MAC Address. All 32 bits are valid. If the NVM is present, the first register (RAL0) is loaded from the NVM.

**Note:** The first 16 MAC Addresses are also mapped to CSR addresses 0x5400-0x5478 for backward compatibility.

| Field | Bit(s) | Init. | Type | Description                                                                                                                                                                    |
|-------|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RAL   | 31:0   | X     | RW   | <b>Receive Address Low</b><br>The lower 32 bits of the 48-bit Ethernet MAC Address.<br><b>Note:</b> This field is defined in Big Endian (LS byte of RAL is first on the wire). |

#### 8.2.2.8.15 Receive Address High - RAH[n] (0x0000A204 + 0x8\*n, n=0...127)

These registers contain the upper 16 bits of the 48-bit Ethernet MAC Address. The complete address is {RAH, RAL}. AV determines whether this address is compared against the incoming packet. The AV field is cleared by a master reset.

**Note:** The first receive address register (RAR0) is also used for exact match pause frame checking (DA matches the first register). RAR0 should always be used to store the individual Ethernet MAC Address of the adapter. After reset, if the NVM is present, the first register (Receive Address Register 0) is loaded from the *IA* field in the NVM, its *Address Select* field is 00b, and its *Address Valid* field is 1b. If no NVM is present, the *Address Valid* field is 0b. The *Address Valid* field for all of the other registers are 0b. The first 16 MAC Addresses are also mapped to CSR addresses 0x5404 - 0x547C for backward compatibility.

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                  |

| POOL_ENA | 31:0   | X     | RW   | <b>Pool Enable bit array</b><br>Each couple of registers '2*n' and '2*n+1' are associated with Ethernet MAC Address Filter 'n' as defined by RAL[n] and RAH[n]. Each bit when set, enables packet reception with the associated Pools as described here:<br>Bit 'i' in register '2*n' is associated with POOL 'i'.<br>Bit 'i' in register '2*n+1' is associated with POOL '32+i'. |

### 8.2.2.8.17 Packet Split Receive Type Register - PSRTYPE[n] (0x0000EA00 + 0x4\*n, n=0...63)

#### Notes:

- This register must be initialized by software.
- Packets are split according to the lowest-indexed entry that applies to the packet and that is enabled. For example, if bits 4 and 8 are set, an IPv4 packet that is not TCP is split after the IPv4 header. The exception to this rule is for tunnel packets. If PSR\_TYPE15 (split on tunnel) or PSR\_TYPE16 (Split on outer L2 header) is set, they take precedence on the other filters. At most one of those should be set.
- This bit mask table enables or disables each type of header to be split. A value of '1'b enables an entry.
- In virtualization mode, a separate PSRTYPE register is provided per pool up to the number of pools enabled. In non-virtualization mode, only PSRTYPE[0] is used.
- Additional address(es): 0x05480 + 4\*n, n=0... 15

#### 8.2.2.8.18 Redirection Table - RETA[n] (0x0000EB00 + 0x4\*n, n=0...31)

The redirection table has 128 entries in 32 registers.

**Note:** The contents of the redirection table are not defined following reset of the Memory Configuration Registers. System software must initialize the table prior to enabling multiple receive queues. It might also update the redirection table during run time. Such updates of the table are not synchronized with the arrival time of received packets. Therefore, it is not guaranteed that a table update takes effect on a specific packet boundary.

| Field    | Bit(s) | Init. | Type | Description                                                                                                             |
|----------|--------|-------|------|-------------------------------------------------------------------------------------------------------------------------|

#### 8.2.2.8.24 Extended Redirection Table - ERETA[n] (0x0000EE80 + 0x4\*n, n=0...95)

The extended redirection table adds 384 entries to extend RETA in 96 registers.

**Note:** The contents of the extended redirection table are not defined following reset of the Memory Configuration Registers. System software must initialize the Table prior to enabling multiple receive queues. It might also update the redirection table during run time. Such updates of the table are not synchronized with the arrival time of received packets. Therefore, it is not guaranteed that a table update takes effect on a specific packet boundary.

| Field    | Bit(s) | Init. | Type | Description                                                                                                                  |
|----------|--------|-------|------|------------------------------------------------------------------------------------------------------------------------------|
| ENTRY0   | 5:0    | X     | RW   | <b>Entry 0</b><br>Defines the RSS output index for hash value '4*[n+32]', where 'n' is the register index equal to 0...95.   |

#### 8.2.2.8.25 Per-Pool RSS Random Key Register - VFRSSRK[n,m] (0x00018000 + 0x4\*n + 0x40\*m, n=0...15, m=0...63)

The RSS Random Key is 40 bytes wide.

**Note:** Only the 10 first registers in each VF array are implemented (0x00 - 0x24).

| Field | Bit(s) | Init. | Type | Description                                                                        |
|-------|--------|-------|------|------------------------------------------------------------------------------------|

| K2    | 23:16  | 0x0   | RW   | <b>Key 2</b><br>RSS Key Byte '4*n+2' of the RSS random key, for each register 'n'. |
| K3    | 31:24  | 0x0   | RW   | <b>Key 3</b><br>RSS Key Byte '4*n+3' of the RSS random key, for each register 'n'. |

### 8.2.2.8.26 Per-Pool Redirection Table - VFRETA[n,m] (0x00019000 + 0x4\*n + 0x40\*m, n=0...15, m=0...63)

The redirection table has 64 entries in 16 registers.

**Note:** The content of the redirection tables are not defined following reset of the Memory Configuration registers. System software must initialize the table prior to enabling multiple receive queues. It might also update the redirection table during run time. Such updates of the table are not synchronized with the arrival time of received packets. Therefore, it is not guaranteed that a table update takes effect on a specific packet boundary.

| RESERVED | 31:26  | 0x0   | RSV  | Reserved.                                                                                                               |

## 8.2.2.9 Receive DMA Registers

### 8.2.2.9.1 Receive Descriptor Base Address Low - RDBAL[n] (0x00001000 + 0x40\*n, n=0...63 and 0x0000D000 + 0x40\*(n-64), n=64...127)

This register contains the lower 32 bits of the 64-bit descriptor base address. The lower 7 bits are always ignored. The Receive Descriptor Base Address must point to a 128-byte aligned block of data.

| Field | Bit(s) | Init. | Type | Description                                                     |
|-------|--------|-------|------|-----------------------------------------------------------------|
| ZERO  | 6:0    | 0x0   | RW   | <b>Zero</b><br>Ignored on writes. Returns 0 on reads. Bits[6:0] |
| RDBAL | 31:7   | X     | RW   | <b>Receive Descriptor Base Address Low</b><br>Bits[31:7]        |

### 8.2.2.9.2 Receive Descriptor Base Address High - RDBAH[n] (0x00001004 + 0x40\*n, n=0...63 and 0x0000D004 + 0x40\*(n-64), n=64...127)

This register contains the upper 32 bits of the 64-bit descriptor base address.

| Field | Bit(s) | Init. | Type | Description                                                |
|-------|--------|-------|------|------------------------------------------------------------|
| RDBAH | 31:0   | X     | RW   | <b>Receive Descriptor Base Address High</b><br>Bits[63:32] |

### 8.2.2.9.3 Receive Descriptor Length - RDLEN[n] (0x00001008 + 0x40\*n, n=0...63 and 0x0000D008 + 0x40\*(n-64), n=64...127)

**Note:** Additional address(es): 0x0D008 + 0x40\*(n-64), n=64...127

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                         |
|----------|--------|-------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LEN      | 19:0   | 0x0   | RW   | <b>Descriptor Ring Length</b><br>This register sets the number of bytes allocated for descriptors in the circular descriptor buffer. It must be 128-byte aligned (7 LS bits must be set to zero).<br><b>Note:</b> Validated lengths up to 512 K (32 K descriptors). |
| RESERVED | 31:20  | 0x0   | RSV  | Reserved. Reads as 0. Should be written to 0 for future compatibility.                                                                                                                                                                                              |

### 8.2.2.9.4 Receive Descriptor Head - RDH[n] (0x00001010 + 0x40\*n, n=0...63 and 0x0000D010 + 0x40\*(n-64), n=64...127)

**Note:** Additional address(es): 0x0D010 + 0x40\*(n-64), n=64...127

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                                             |
|----------|--------|-------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RDH      | 15:0   | 0x0   | RO   | <b>Receive Descriptor Head</b><br>This register holds the head pointer for the receive descriptor buffer in descriptor units (16-byte datum). The <i>RDH</i> is controlled by hardware. |
| RESERVED | 31:16  | 0x0   | RSV  | Reserved. Should be written with 0.                                                                                                                                                     |

### 8.2.2.9.5 Split Receive Control Registers - SRRCTL[n] (0x00001014 + 0x40\*n, n=0...63 and 0x0000D014 + 0x40\*(n-64), n=64...127)

**Note:** BSIZEHEADER must be bigger than 0 if DESCYPE is equal to 010, 011 100 or 101.  
Additional address(es): 0x0D014 + 0x40\*(n-64), n=64...127 / 0x02100 + 4\*n, [n=0...15]

| Field       | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                   |

### 8.2.2.10.4 DMA Tx TCP Flags Control High - DTXTCPFLGH (0x00004A8C)

This register holds the “mask” bits for the TCP flags in Tx segmentation (described in [Section 7.2.4.7.3](#)).

| Field           | Bit(s) | Init. | Type | Description                                                                                                         |
|-----------------|--------|-------|------|---------------------------------------------------------------------------------------------------------------------|
| TCP_FLG_LST_SEG | 11:0   | 0xF7F | RW   | <b>TCP Flags Last Segment</b><br>Bits that make AND operation with the TCP flags at TCP header in the last segment. |
| RESERVED        | 31:12  | 0x0   | RSV  | Reserved.                                                                                                           |

### 8.2.2.10.5 Transmit Descriptor Base Address Low - TDBAL[n] (0x00006000 + 0x40\*n, n=0...127)

This register contains the lower 32 bits of the 64-bit descriptor base address. The lower 7 bits are ignored. The Transmit Descriptor Base Address must point to a 128-byte aligned block of data.

| Field | Bit(s) | Init. | Type | Description                                                     |
|-------|--------|-------|------|-----------------------------------------------------------------|
| ZERO  | 6:0    | 0x0   | RW   | <b>Zero</b><br>Ignored on writes. Returns 0 on reads. Bits[6:0] |
| TDBAL | 31:7   | X     | RW   | <b>Transmit Descriptor Base Address Low</b><br>Bits[31:7]       |

### 8.2.2.10.6 Transmit Descriptor Base Address High - TDBAH[n] (0x00006004 + 0x40\*n, n=0...127)

This register contains the upper 32 bits of the 64-bit descriptor base address.

| Field | Bit(s) | Init. | Type | Description                                                 |
|-------|--------|-------|------|-------------------------------------------------------------|
| TDBAH | 31:0   | X     | RW   | <b>Transmit Descriptor Base Address High</b><br>Bits[63:32] |

### 8.2.2.10.7 Transmit Descriptor Length - TDLEN[n] (0x00006008 + 0x40\*n, n=0...127)

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                        |
|----------|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LEN      | 19:0   | 0x0   | RW   | <b>Descriptor Ring Length</b><br>This register sets the number of bytes allocated for descriptors in the circular descriptor buffer. It must be 128-byte aligned (7 LS bit must be set to zero).<br><b>Note:</b> Validated Lengths up to 512 K (32 K descriptors). |
| RESERVED | 31:20  | 0x0   | RSV  | Reserved. Reads as 0. Should be written to 0.                                                                                                                                                                                                                      |

### 8.2.2.10.8 Transmit Descriptor Head - TDH[n] (0x00006010 + 0x40\*n, n=0...127)

**Note:** The values in these registers might point to descriptors that are still not in the host memory. As a result, the host cannot rely on these values to determine which descriptor to release.

**Note:** The only time that software should write to this register is after a reset (hardware reset or CTRL.RST) and before enabling the transmit function (TXDCTL.ENABLE). If software were to write to this register while the transmit function was enabled, the on-chip descriptor buffers might be invalidated and hardware could become confused.

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                                |
|----------|--------|-------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TDH      | 15:0   | 0x0   | RO   | <b>Transmit Descriptor Head</b><br>This register contains the head pointer for the transmit descriptor ring. It points to a 16-byte datum. Hardware controls this pointer. |
| RESERVED | 31:16  | 0x0   | RSV  | Reserved. Should be written with 0.                                                                                                                                        |

### 8.2.2.10.9 Transmit Descriptor Tail - TDT[n] (0x00006018 + 0x40\*n, n=0...127)

**Note:** Hardware attempts to transmit all packets referenced by descriptors between head and tail.

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                  |
|----------|--------|-------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TDT      | 15:0   | 0x0   | RW   | <b>Transmit Descriptor Tail</b><br>This register contains the tail pointer for the transmit descriptor ring. It points to a 16B datum. Software writes the tail pointer to add more descriptors to the transmit ready queue. |
| RESERVED | 31:16  | 0x0   | RSV  | Reserved. Reads as 0. Should be written to 0 for future compatibility.                                                                                                                                                       |

### 8.2.2.10.10 Transmit Descriptor Control - TXDCTL[n] (0x00006028 + 0x40\*n, n=0...127)

This register controls the fetching and write back of transmit descriptors. The three threshold values are used to determine when descriptors are read from and written to host memory. For *PTHRESH* and *HTHRESH* recommended settings, see [Section 7.2.3.4, “Transmit Descriptor Fetching”](#).

**Note:** When *WTHRESH* = 0b, only descriptors with the *RS* bit set are written back.

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

### 8.2.2.10.11 Tx Descriptor Completion Write Back Address Low - TDWBAL[n] (0x00006038 + 0x40\*n, n=0...127)

| Field      | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                    |
|------------|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| HEAD_WB_EN | 0      | 0b    | RW   | <b>Head Write-Back Enable</b><br>0b = Head write-back is disabled.<br>1b = Head write-back is enabled.<br>When HEAD_WB_EN is set, Tx descriptors are not written back.                                                         |
| RESERVED   | 1      | 0b    | RSV  | Reserved.                                                                                                                                                                                                                      |
| HEADWB_LOW | 31:2   | 0x0   | RW   | <b>Head Write-Back Low</b><br>Lowest 32 bits of the head write-back memory location (DWORD aligned). The last two bits of this field are ignored and are always read as 00b, meaning that the actual address is QWORD aligned. |

### 8.2.2.10.12 Tx Descriptor Completion Write Back Address High - TDWBAH[n] (0x0000603C + 0x40\*n, n=0...127)

| Field       | Bit(s) | Init. | Type | Description                                                                                                |
|-------------|--------|-------|------|------------------------------------------------------------------------------------------------------------|
| HEADWB_HIGH | 31:0   | 0x0   | RW   | <b>Head Write-Back High</b><br>Highest 32 bits of Head write-back memory location (for 64-bit addressing). |

### 8.2.2.10.13 DMA Tx TCP Max Allow Size Requests - DTXMXSZRQ (0x00008100)

This register limits the total number of data bytes that might be in outstanding PCIe requests from the host memory. This allows requests to send low latency packets to be serviced in a timely manner, as this request is serviced right after the current outstanding requests are completed.

| Field             | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                           |
|-------------------|--------|-------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MAX_BYTES_NUM_REQ | 11:0   | 0x10  | RW   | <b>Max Allowed Number of Bytes Requests</b><br>The maximum allowed amount of 256 bytes outstanding requests. If the total size request is higher than the amount in the field, no arbitration is done and no new packet is requested. |
| RESERVED          | 31:12  | 0x0   | RSV  | Reserved.                                                                                                                                                                                                                             |

### 8.2.2.10.14 Multiple Transmit Queues Command Register - MTQC (0x00008120)

**Note:** For permitted value and functionality of DCB\_ENA, VT\_ENA, and NUM\_TC\_OR\_Q. For Tx queue assignment in DCB and VT modes, see [Table 7-27 on page 313](#).

**Note:** This register can be modified only as part of the initialization phase.

| Field   | Bit(s) | Init. | Type | Description                                                                                                                                                                               |

| RS_ENA   | 31     | 0b    | SC   | <b>Rate Scheduler Enable</b><br>Tx QCN rate scheduler enable for the Tx queue indexed by <i>TXDQ_IDX</i> field in RTTDQSEL register.<br>0b = The QCN rate factor programmed in this register is meaningless, and the switch for that queue is always forced to "on". The queue is not rate-controlled for QCN.<br>1b = The QCN rate programmed in this register is enforced (i.e., the queue is rate controlled for QCN). At the time it is set, the current timer value is loaded into the Timestamp stored for that entry.<br>Bandwidth Group Assignment of this TC to a bandwidth group. Each TC must be assigned to a different BWG number, unless the TC is a member of a BWG. No more than two TCs can share the same BWG. |

### 8.2.2.11.9 DCB Transmit QCN Rate-Scheduler Status - RTTQCNRS (0x00004988)

128 internal registers indirectly addressed via RTTDQSEL.*TXDQ\_IDX* (refer to [Section 8.2.2.11.4](#)).

| Field | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------|--------|-------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MIFS  | 31:0   | 0x0   | RW   | <b>Minimum Inter-Frame Spacing</b><br>Tx QCN rate scheduler current minimum inter-frame spacing for the Tx queue indexed by <i>TXDQ_IDX</i> field in RTTDQSEL register.<br>When read, it is the current algebraic value of the MIFS interval for the queue, expressed in byte units (31 LS-bits taken), relative to the QCN rate scheduler. It is obtained by hardware subtracting the current value of the timer associated to that QCN rate-scheduler from the timestamp stored for that queue. A strict positive value means a switch in "off" state. It is expressed in 2's complement format. |

### 8.2.2.11.10 DCB Transmit QCN Rate Reset - RTTQCNRR (0x0000498C)

| Field         | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                               |
