## 8.2.2.13 Timers Registers

### 8.2.2.13.1 TCP Timer - TCPTIMER (0x0000004C)

| Field          | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DURATION       | 7:0    | 0x0   | RW   | <b>Duration</b><br>Duration (in ms) of the TCP interrupt interval.                                                                                                                                                                                                                                                                                                                                                       |
| KICKSTART      | 8      | 0b    | RWS  | <b>Counter Kick-Start</b><br>0b = No effect.<br>1b = Kick-starts the counter down-count from the initial value defined in <i>Duration</i> field.                                                                                                                                                                                                                                                                         |
| TCPCOUNTEN     | 9      | 0b    | RW   | <b>TCP Count Enable</b><br>0b = TCP timer counting is disabled.<br>1b = TCP timer counting is enabled.<br>Upon enabling, TCP counter counts from its internal state. If the internal state is equal to zero, down-count does not restart until <i>KICKSTART</i> is activated.<br>If the internal state is not 0b, down-count continues from the internal state. This enables a pause of the counting for debug purposes. |
| TCPCOUNTFINISH | 10     | 0b    | RWS  | <b>TCP Count Finish</b><br>This bit enables software to trigger a TCP timer interrupt, regardless of the internal state.<br>0b = No effect.<br>1b = Triggers an interrupt, and resets the internal counter to its initial value. Down-count does not restart until either <i>KICKSTART</i> is activated or <i>Loop</i> is set.                                                                                           |
| LOOP           | 11     | 0b    | RW   | <b>TCP Loop</b><br>0b = TCP counter stops at zero value, and does not re-start until <i>KICKSTART</i> is activated.<br>1b = TCP counter reloads duration each time it reaches zero, and goes on down-counting from this point without kick-starting.                                                                                                                                                                     |
| RESERVED       | 31:12  | 0x0   | RSV  | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                |

## 8.2.2.14 FCoE Registers

### 8.2.2.14.1 FC Indirect DMA Context: User Descriptor PTR Low - FCPTRL (0x00002410)

| Field   | Bit(s) | Init. | Type | Description                                                                                                                                                                                      |
|---------|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PTR_LOW | 31:0   | X     | RW   | <b>User Descriptor PTR Low</b><br>Four least significant bytes of the physical pointer to the User Descriptor list. The pointer must be 16-byte aligned so the 4 LS bits are read-only as zeros. |

### 8.2.2.14.2 FC Indirect DMA Context: User Descriptor PTR High - FCPTRH (0x00002414)

| Field  | Bit(s) | Init. | Type | Description                                                                                                         |
|--------|--------|-------|------|---------------------------------------------------------------------------------------------------------------------|
| PTR_HI | 31:0   | X     | RW   | <b>User Descriptor PTR High</b><br>Four most significant bytes of the physical pointer to the User Descriptor list. |

### 8.2.2.14.3 FC Indirect DMA Context: Buffer Control - FCBUFF (0x00002418)

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                       |
|----------|--------|-------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VALID    | 0      | 0b    | RW   | <b>DMA Context Valid</b><br>When set to 1b, indicates that the context is valid. If software clears the <i>VALID</i> bit, the software should poll it until it is actually cleared by hardware before unlocking the user buffers. |
| FIRST    | 1      | 0b    | RW   | <b>DMA First</b><br>This bit is a status indication. Software should clear it during FC context programming. The DMA unit sets this bit when it receives a frame that matches the context and marked by the Filter unit as first. |
| LAST     | 2      | 0b    | RW   | <b>DMA Last</b><br>This bit is a status indication. Software should clear it during FC context programming. Hardware sets this bit when it exhausts the last user buffer.                                                         |
| BUFFSIZE | 4:3    | 00b   | RW   | <b>Buffer Size</b><br>This field defines the user buffer size used in this context as follows:<br>00b = 4 KB<br>01b = 8 KB<br>10b = 16 KB<br>11b = 64 KB                                                                          |
| WRCONTX  | 5      | 0b    | RW   | <b>Write DDP Context</b><br>0b = Rad exchange context aimed for initiator (originator) usage.<br>1b = Write exchange context aimed for target (responder) usage.                                                                  |
| BUFFCNT  | 15:6   | 0x0   | RW   | <b>Buffer Count</b><br>Defines the number of the user buffer while 0x00 equals 1024. It is programmed by the software and updated by hardware during reception.                                                                   |
| OFFSET   | 31:16  | 0x0   | RW   | <b>User Buffer Offset</b><br>Byte offset within the user buffer to which the FC data of large FC receive should be posted.                                                                                                        |

#### 8.2.2.14.4 FC Indirect DMA Context: Receive DMA RW - FCDMARW (0x00002420)

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                         |
|----------|--------|-------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FCOESEL  | 10:0   | 0x0   | RW   | <b>FCoE Context Select</b><br>This field defines the FCoE Rx context index (equals the RX_ID for that context).                                                                                                                                     |

### 8.2.2.15 Flow Director Registers

These registers are used to control the flow director functionality.

#### 8.2.2.15.1 Flow Director Filters Control Register - FDIRCTRL (0x0000EE00)

**Note:** This register should be configured ONLY as part of the Flow Director initialization flow or Clearing the Flow Director table. Programming of this register with non zero value in the *PBALLOC* field initializes the Flow Director table.

| Field                | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| REPORT_STATUS        | 5      | 0b    | RW   | <b>Report Status</b><br>Report Flow Director filter's status in the <i>RSS</i> field of the Rx descriptor for packets that matches a Flow Director filter. Enabling the Flow Director filter's status, the <i>RXCSUM.PCSD</i> bit ( <a href="#">Section 8.2.2.8.1</a> ) should be set as well (disabling the fragment checksum).<br><b>Note:</b> The Flow Director filter <i>Status</i> and <i>Error</i> bits in the <i>Extended Status</i> and <i>Error</i> fields in the Rx descriptor are always enabled. |
| RESERVED             | 6      | 0b    | RSV  | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| REPORT_STATUS_ALWAYS | 7      | 0b    | RW   | <b>Report Status Always</b><br>Report Flow Director status in the <i>RSS</i> field of the Rx descriptor on any packet that can be a candidate for the Flow Director filters. This bit can be set to 1b only when both the <i>RXCSUM.PCSD</i> bit and the <i>REPORT_STATUS</i> bit in this register are set.                                                                                                                                                                                                  |
| DROP_QUEUE           | 14:8   | 0x0   | RW   | <b>Drop Queue</b><br>Absolute Rx queue index used for the dropped packets. Software might set this queue to an empty one by setting the <i>RDLEN[n]</i> to 0x0.                                                                                                                                                                                                                                                                                                                                              |
| DROP_NO_MATCH        | 15     | 0b    | RW   | <b>Drop No Match</b><br>If set, send to the <i>DROP_QUEUE</i> packets that were candidates for Flow Director and did not match any filters. Candidature of packets is defined in <a href="#">Table 7-5 on page 271</a> .                                                                                                                                                                                                                                                                                     |
| FLEX_OFFSET          | 20:16  | 0x0   | RW   | <b>Flexible Offset</b><br>Offset within the first 64 bytes of the packet of a flexible 2-byte tuple. The offset is defined in word units counted from the first byte in the destination Ethernet MAC Address.                                                                                                                                                                                                                                                                                                |

| Field       | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------|--------|-------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FILTERMODE  | 23:21  | 000b  | RW   | <b>Filter Mode</b><br>Defines the fields on which the Flow director acts:<br>000b = IPMODE — L3/L4 tuple.<br>001b = MACVLANMODE — Acts on the MAC and VLAN.<br>010b = Cloud: NVGRE — Based on TNI, inner MAC, inner VLAN.<br>VXLAN — Based on VNI, inner MAC, inner VLAN.<br>All other values are reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| MAX_LENGTH  | 27:24  | 0x0   | RW   | <b>Max Linked List Length</b><br>This field defines the maximum recommended linked list associated to any Hash value. Packets that match filters that exceed <i>MAX_LENGTH</i> are reported with an active <i>Length</i> bit in the <i>Extended Error</i> field. In addition, "Drop" filters that exceed the <i>MAX_LENGTH</i> are posted to the Rx queue defined in the filter context rather than the <i>DROP_QUEUE</i> defined in this register.<br><i>MAX_LENGTH</i> is defined in units of 2 filters, and exceeding it reflects the addition of two more filters.<br><b>Note:</b> Software should set this field to a value that indicates exceptional long buckets. Supporting 32K filters with good hash scheme key, it is expected that a value of 0xA might be a good choice. |
| FULL_THRESH | 31:28  | 0x0   | RW   | <b>Full Threshold</b><br>A recommended minimum number of flows that should remain unused (defined in units of 16 filters). When software exceeds this threshold (too low number of unused flows), hardware generates the Flow Director Full interrupt. Software should avoid additional programming following this interrupt.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

### 8.2.2.15.2 Flow Director Filters Source IPv6 - FDIRSIPV6[n] (0x0000EE0C + 0x4\*n, n=0...2)

| Field | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------|--------|-------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IP6SA | 31:0   | 0x0   | RW   | <b>IPv6 Source Address</b><br>Three LS Dwords of the source IPv6 address.<br>The FDIRIPSA register contains the MS Dword of the IP6 address. The LS byte of the FDIRIPSA register is first on the wire and the MS byte of FDIRSIPV6[2] is last on the wire.<br>In MACVLANMODE, FDIRSIPV6_0[31:0] and FDIRSIPV6_1[15:0] hold the destination MAC Address value. FDIRSIPV6_1[31:16] and FDIRSIPV6_2[31:0] are reserved and should be set to 0x0. |

### 8.2.2.15.3 Flow Director Filters IP SA - FDIRIPSA (0x0000EE18)

| Field | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                            |
|-------|--------|-------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IP4SA | 31:0   | 0x0   | RW   | <b>IPv4 Source Address</b><br>Source IPv4 address or MS Dword of the source IPv6 address, where the field is defined in Big Endian (LS byte is first on the wire).<br>In MACVLANMODE, this field is reserved and should be set to 0x0. |

#### 8.2.2.15.4 Flow Director Filters IP DA - FDIRIPDA (0x0000EE1C)

| Field | Bit(s) | Init. | Type | Description                                                                                                                                                                |
|-------|--------|-------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IP4DA | 31:0   | 0x0   | RW   | <b>IPv4 Destination Address</b><br>This field is defined in Big Endian (LS byte is first on the wire).<br>In MACVLANMODE, this field is reserved and should be set to 0x0. |

#### 8.2.2.15.5 Flow Director Filters Port - FDIRPORT (0x0000EE20)

| Field       | Bit(s) | Init. | Type | Description                                                                                                                                                                                                |
|-------------|--------|-------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SOURCE      | 15:0   | 0x0   | RW   | <b>Source Port Number</b><br>This field is defined in Little Endian (MS byte is first on the wire).<br>In MACVLANMODE and cloud modes (NVGRE/VXLAN), this field is reserved and should be set to 0x0.      |
| DESTINATION | 31:16  | 0x0   | RW   | <b>Destination Port Number</b><br>This field is defined in Little Endian (MS byte is first on the wire).<br>In MACVLANMODE and cloud modes (NVGRE/VXLAN), this field is reserved and should be set to 0x0. |

#### 8.2.2.15.6 Flow Director Filters VLAN and FLEX Bytes - FDIRVLAN (0x0000EE24)

| Field | Bit(s) | Init. | Type | Description                                                                                                                                                                          |
|-------|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VLAN  | 15:0   | 0x0   | RW   | <b>VLAN Tag</b><br>This field is defined in Little Endian (MS byte is first on the wire). The <i>CFI</i> bit must be set to zero and it is not checked by hardware.                  |
| FLEX  | 31:16  | 0x0   | RW   | <b>Flexible</b><br>Flexible tuple data as defined by the <i>FLEX_OFFSET</i> field in the FDIRCTRL register, where the field is defined in Big Endian (LS byte is first on the wire). |

#### 8.2.2.15.7 Flow Director Filters Hash Signature - FDIRHASH (0x0000EE28)

| Field              | Bit(s) | Init. | Type | Description                                                                                                                                                                               |
|--------------------|--------|-------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| HASH               | 14:0   | 0x0   | RW   | <b>Hash</b><br>Bucket hash value that identifies a filter's linked list                                                                                                                   |
| BUCKET_VALID       | 15     | 0b    | RW   | <b>Bucket Valid</b><br>The <i>Valid</i> bit is set by hardware whenever there is at least one filter assigned to this hash.                                                               |
| SIGNATURE_SW_INDEX | 30:16  | 0x0   | RW   | <b>Signature/Software Index</b><br>Flow Director Filter Signature for Signature filters and SW-index for perfect match filters.<br>In perfect match mode, the two MS bits should be zero. |
| RESERVED           | 31     | 0b    | RSV  | Reserved.                                                                                                                                                                                 |

### 8.2.2.15.8 Flow Director Filters Command Register - FDIRCMD (0x0000EE2C)

| Field         | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

### 8.2.2.15.18 Flow Director Filters Miss Match Statistics - FDIRMISS (0x0000EE5C)

| Field | Bit(s) | Init. | Type | Description                                                                                                                                  |
|-------|--------|-------|------|----------------------------------------------------------------------------------------------------------------------------------------------|
| PCNT  | 31:0   | 0x0   | RC   | <b>Packet Count</b><br>Number of packets that miss-matched any Flow Director filter. The counter is stacked at 0xFF...F and cleared on read. |

### 8.2.2.15.19 Flow Director Filters Lookup Table HASH Key - FDIRHKEY (0x0000EE68)

| Field | Bit(s) | Init.      | Type | Description                                       |
|-------|--------|------------|------|---------------------------------------------------|
| KEY   | 31:0   | 0x80000001 | RW   | <b>Key</b><br>Programmable hash lookup table key. |

### 8.2.2.15.20 Flow Director Filters Signature HASH Key - FDIRSKEY (0x0000EE6C)

| Field | Bit(s) | Init.      | Type | Description                               |
|-------|--------|------------|------|-------------------------------------------|
| KEY   | 31:0   | 0x80800101 | RW   | <b>Key</b><br>Programmable signature key. |

### 8.2.2.15.21 Flow Director Filters Other Mask - FDIRM (0x0000EE70)

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                      |
|----------|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VLANID   | 0      | 0b    | RW   | <b>Mask VLAN ID Tag</b><br>When cleared, the 12 bits of the VLAN ID tag are meaningful for the filtering functionality.                                                                                                                                                                                                                          |
| VLANP    | 1      | 0b    | RW   | <b>Mask VLAN Priority Tag</b><br>When cleared, the 3 bits of the VLAN Priority are meaningful for the filtering functionality.                                                                                                                                                                                                                   |
| POOL     | 2      | 0b    | RW   | <b>Mask Pool</b><br>When cleared, the target Pool number is meaningful for the filtering functionality.                                                                                                                                                                                                                                          |
| L4P      | 3      | 0b    | RW   | <b>Mask L4 Protocol</b><br>When cleared, the UDP/TCP/SCTP protocol type is meaningful for the filtering functionality.<br><b>Note:</b> For the Flow Director filtering aspects, SCTP is treated as if it is TCP.                                                                                                                                 |
| FLEX     | 4      | 0b    | RW   | <b>Mask Flexible Tuple</b><br>When cleared, the 2 bytes of the Flexible Tuple are meaningful for the filtering functionality.                                                                                                                                                                                                                    |
| DIPV6    | 5      | 0b    | RW   | <b>Mask Destination IPv6</b><br>When cleared, the compare against the IP6AT filter is meaningful for IPv6 packets.                                                                                                                                                                                                                               |
| L3P      | 6      | 0b    | RW   | <b>Mask IP Type Comparison</b><br>To block all IP comparison, the following should also be set: <i>DIPV6</i> field, <i>FDIRIP6M</i> register, <i>FDIRSIP4M</i> register, and <i>FDIRDIP4M</i> register (see <a href="#">Section 8.2.2.15.22</a> , <a href="#">Section 8.2.2.15.11</a> , and <a href="#">Section 8.2.2.15.10</a> , respectively). |

| MFS      | 31:16  | 0x5EE | RW   | <b>Maximum Frame Size</b><br>This field defines the maximum frame size (MFS) in bytes units from Ethernet MAC Addresses up to and including the CRC. Frames received that are larger than this value are dropped.<br>This field is meaningful when jumbo frames are enabled (HLREG0.JUMBOEN = 1b). When Jumbo frames are not enabled the device uses a hard-wired value of 1518 for this field.<br>The MFS does not include the 4 bytes of the VLAN header. Packets with VLAN header might be as large as MFS + 4.<br>When Double VLAN is enabled the device adds 8 to the MFS for any packet.<br>When E-tags are enabled, the device adds 12 to the MFS for any packet.<br>This value has no effect on transmit frames. It is the responsibility of software to limit the size of transmit frames.<br><b>Note:</b> Packets to/from MC are limited to 2 KB even when jumbo frames are enabled. |

### 8.2.2.16.7 Link Status Register - LINKS (0x000042A4)

### 8.2.2.17 Statistic Registers

All Statistics registers are cleared on read. In addition, they stick at 0xFF...F when the maximum value is reached.

For the receive statistics, a packet is indicated as received if it passes the device filters and is placed into the packet buffer memory. A packet does not have to be DMA'd to host memory to be counted as received.

Due to divergent paths between interrupt generation and logging of relevant statistics counts, it might be possible to generate an interrupt to the system for a noteworthy event prior to the associated statistics count actually being incremented. This is extremely unlikely due to expected delays associated with the system interrupt collection and ISR delay, but might be an explanation for interrupt statistics values that do not quite make sense. Hardware guarantees that any event noteworthy of inclusion in a statistics count is reflected in the appropriate count within 1  $\mu$ s; a small time-delay prior to reading the statistics might be required to avoid a potential mismatch between an interrupt and its cause.

If RSC is enabled, statistics are collected before RSC is applied to the packets. If TSO is enabled, statistics are collected after segmentation.

All byte (octet) counters composed of two registers can be fetched by two consecutive 32-bit accesses while reading the low 32-bit register first, or a single 64-bit access.

All receive statistic counters count the packets and bytes before coalescing by the RSC logic or FCoE DDP logic. All receive statistic counters in the filter unit might count packets that might be dropped by the packet buffer or receive DMA. Same comment is valid for the byte counters associated with these packet counters: PRC64, PRC127, PRC255, PRC511, PRC1023, PRC1522, BPRC, MPRC, GPRC, RXNFGPC, RUC, and ROC.

#### 8.2.2.17.1 Queue Packets Received Count - QPRC[n] (0x00001030 + 0x40\*n, n=0...15)

| Field | Bit(s) | Init. | Type | Description                                                                                                                                                                                            |
|-------|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRC   | 31:0   | 0x0   | RC   | <b>Packets Received Count</b><br>Number of packets received for the Queue.<br>FCoE packets are counted in the QRPC even if they are posted only to the DDP queue (with no traces in the legacy queue). |

#### 8.2.2.17.2 Queue Bytes Received Count Low - QBRC\_L[n] (0x00001034 + 0x40\*n, n=0...15)

| Field | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                            |
|-------|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BRC_L | 31:0   | 0x0   | RC   | <b>Bytes Received Count Low</b><br>Lower 32 bits of the statistic counter.<br>The QBRC_L[n] and QBRC_H[n] registers make up a logical 36-bit counter of received bytes that were posted to the programmed Rx queues of the packets counted by the QPRC[n]. The counter counts all bytes posted to the host before VLAN strip. Furthermore, bytes of RSC and FCoE are counted before coalescing or DDP. |

### 8.2.2.17.3 Queue Bytes Received Count High - QBRC\_H[n] (0x00001038 + 0x40\*n, n=0...15)

| Field    | Bit(s) | Init. | Type | Description                                                                                                          |
|----------|--------|-------|------|----------------------------------------------------------------------------------------------------------------------|

| RESERVED | 31:4   | 0x0   | RSV  | Reserved.                                                                                                            |

### 8.2.2.17.4 Queue Packets Received Drop Count - QPRDC[n] (0x00001430 + 0x40\*n, n=0...15)

| Field | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------|--------|-------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRDC  | 31:0   | 0x0   | RC   | <b>Packets Received Drop Count</b><br>Number of receive packets dropped for the queue.<br>Packets are dropped per queue in one of three cases: <ul style="list-style-type: none"><li>Rx Queue is disabled in the RXDCTL[n] register (this includes packets sent to this queue due to the flow director drop no match mechanism or drop action).</li><li>No free descriptors in the Rx queue while hardware is set to <i>DROP_EN</i> in the SRRCTL[n] register or in the PFQDE register.</li><li>Packet size is larger than RLPML while <i>RLPML_EN</i> is set in the RXDCTL[n] register.</li></ul> |

### 8.2.2.17.5 Receive Queue Statistic Mapping Registers - RQSMR[n] (0x00002300 + 0x4\*n, n=0...31)

These registers define the mapping of the receive queues to the per-queue statistics. Several queues can be mapped to a single statistic register. Each statistic register counts the number of packets and bytes of all the queues that are mapped to that statistics. The registers counting Rx queue statistics are: QPRC, QBRC, and QPRDC. For example, setting RQSMR[0].Q\_MAP[0] to "3" maps Rx queue 0 to the counters QPRC[3], QBRC[3], and QPRDC[3]. Setting RQSMR[2].Q\_MAP[1] to "5" maps Rx queue 9 to the QPRC[5], QBRC[5], and QPRDC[5].

| Field    | Bit(s) | Init. | Type | Description                                                                                                                          |

### 8.2.2.17.37 Packets Received [1024 to Max Bytes] Count - PRC1522 (0x00004070)

| Field   | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------|--------|-------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRC1522 | 31:0   | 0x0   | RW   | <b>Packets Received Count (1024-Max Bytes)</b><br>Number of packets received that are 1024-Max bytes in length (from <Destination Address> through <CRC>, inclusively).<br>This registers counts packets that pass L2 filtering regardless on receive enablement and does not include received flow control packets.<br>The maximum is dependent on the current receiver configuration and the type of packet being received. If a packet is counted in Receive Oversized Count, it is not counted in this register.<br>Due to changes in the standard for maximum frame size for VLAN tagged frames in 802.3, this device accepts packets which have a maximum length of 1522 bytes. The RMON statistics associated with this range has been extended to count 1522 byte long packets. |

### 8.2.2.17.38 Good Packets Received Count - GPRC (0x00004074)

| Field | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                          |
|-------|--------|-------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GPRC  | 31:0   | 0x0   | RO   | <b>Good Packets Received Count</b><br>Number of good (non-erred) Rx packets (from the network) that pass L2 filtering and have legal length.<br>This registers counts packets regardless of receive enable, and does not count flow control packets. |

### 8.2.2.17.39 Broadcast Packets Received Count - BPRC (0x00004078)

| Field | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                              |
|-------|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BPRC  | 31:0   | 0x0   | RO   | <b>Broadcast Packets Received Count</b><br>Number of good (non-erred) broadcast packets received.<br>This register does not count received broadcast packets when the broadcast address filter is disabled. The counter counts packets regardless of receive enablement. |

### 8.2.2.17.40 Multicast Packets Received Count - MPRC (0x0000407C)

| Field | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                          |
|-------|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MPRC  | 31:0   | 0x0   | RO   | <b>Multicast Packets Received Count</b><br>Number of good (non-erred) multicast packets received that pass L2 filtering (excluding Broadcast packets).<br>This register does not count received flow control packets. This register counts packets regardless of receive enablement. |

### 8.2.2.17.41 Good Packets Transmitted Count - GPTC (0x00004080)

| Field | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                   |
|-------|--------|-------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GPTC  | 31:0   | 0x0   | RC   | <b>Good Packets Transmitted Count</b><br>Number of good packets transmitted. This register counts good (non-erred) transmitted packets.<br>A good transmit packet is considered one that is 64 or more bytes (from <Destination Address> through <CRC>, inclusively) in length. The register counts transmitted clear packets, secure packets and FC packets. |

### 8.2.2.17.42 Good Octets Received Count Low - GORCL (0x00004088)

| Field | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                            |
|-------|--------|-------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CNT_L | 31:0   | 0x0   | RC   | <b>Count Low</b><br>Lower 32 bits of the "Good Octets Received" counter.<br>The GORCL and GORCH registers make up a logical 36-bit octet counter of the packets counted by the GPRC (see <a href="#">Section 8.2.2.17.38</a> ). This register includes bytes received in a packet from the <i>Destination Address</i> field through the <i>CRC</i> field, inclusively. |

### 8.2.2.17.43 Good Octets Received Count High - GORCH (0x0000408C)

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                          |
|----------|--------|-------|------|------------------------------------------------------------------------------------------------------------------------------------------------------|

#### 8.2.2.17.85 Sideband Receive Dropped Packet Count - B2OSDPC (0x000041F0)

**Note:** Although the name is B2OSDPC, this counter includes all drops from the BMC, even if sent to LAN. This counter is shared between all ports, and counts events of packets dropped regardless of their destination port.

| Field   | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------|--------|-------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| B2OSDPC | 31:0   | 0x0   | RW   | <b>BMC-to-OS Dropped Packet Count</b><br>Counts the number of packets received from the BMC interface receive that were dropped.<br>The following causes can create a drop: <ul style="list-style-type: none"><li>• Memory buffer full.</li><li>• Pause packet.</li><li>• PT packet without SA match or requires enables.</li><li>• MCTP drop (unsupported message type).</li><li>• Length error.</li><li>• Reject by specific interface (SMBus abort, MCTP reject, RMII reject).</li></ul> |

#### 8.2.2.17.86 Fiber Channel CRC Error Count - FCCRC (0x00005118)

| Field    | Bit(s) | Init. | Type | Description                                                                                |
|----------|--------|-------|------|--------------------------------------------------------------------------------------------|
| CRC_CNT  | 15:0   | 0x0   | RC   | <b>FC CRC Count</b><br>Counts the number of packets with good Ethernet CRC and bad FC CRC. |
| RESERVED | 31:16  | X     | RSV  | Reserved.                                                                                  |

#### 8.2.2.17.87 Queue Packets Transmitted Count - QPTC\_ALIAS[n] (0x00006030 + 0x40\*n, n=0...15; RC)

Field definitions are the same as those defined in [Section 8.2.2.17.89](#).

### 8.2.2.17.88 Transmit Queue Statistic Mapping Registers - TQSM[n] (0x00008600 + 0x4\*n, n=0...31)

These registers define the mapping of the transmit queues to the per-queue statistics. Several queues can be mapped to a single statistic register. Each statistic register counts the number of packets and bytes of all the queues that are mapped to that statistics. The registers counting Tx queue statistics are QPTC and QBTC (refer to [Section 8.2.2.17.89](#), [Section 8.2.2.17.90](#), and [Section 8.2.2.17.91](#)).

| Field    | Bit(s) | Init. | Type | Description                                                                                                                          |
|----------|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------------------|
| Q_MAP_0  | 3:0    | 0x0   | RW   | <b>Queue Map 0</b><br>For each register 'n', Q_MAP[0] defines the per queue statistic registers that are mapped to Tx queue '4*n+0'. |

### 8.2.2.17.89 Queue Packets Transmitted Count - QPTC[n] (0x00008680 + 0x4\*n, n=0...15)

**Note:** Additional address(es): 0x06030 + 0x40\*n, n=0...15

| Field | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------|--------|-------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PTC   | 31:0   | 0x0   | RC   | <b>Packets Transmitted Count</b><br>Number of packets transmitted for the Queue.<br>A packet is considered as transmitted if it is forwarded to the MAC unit for transmission to the network and/or is accepted by the internal Tx-to-Rx switch enablement logic. Packets dropped due to anti-spoofing filtering, or traffic sent to the BMC and blocked due to security violations, or loopback packets that are rejected by the Tx-to-Rx switch, are not counted. |

### 8.2.2.17.90 Queue Bytes Transmitted Count Low - QBTC\_L[n] (0x00008700 + 0x8\*n, n=0...15)

| Field | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------|--------|-------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BTC_L | 31:0   | 0x0   | RC   | <b>Bytes Transmitted Count Low</b><br>Lower 32 bits of the statistic counter.<br>The QBTC_L and QBTC_H registers make up a logical 36-bit counter of transmitted bytes of the packets counted by the matched QPTC counter. These registers count all bytes in the packets from the <i>Destination Address</i> field through the <i>CRC</i> field, inclusively. These registers must be accessed as two consecutive 32-bit entities while QBTC_L register is read first, or a single 64-bit read cycle. Each register is read-cleared. In addition, it sticks at 0xFF...F to avoid overflow. |

### 8.2.2.17.91 Queue Bytes Transmitted Count High - QBTC\_H[n] (0x00008704 + 0x8\*n, n=0...15)

| Field    | Bit(s) | Init. | Type | Description                                                                                                              |
|----------|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------|
| BTC_H    | 3:0    | 0x0   | RC   | <b>Bytes Transmitted Count High</b><br>Higher 4 bits of the statistic counter described in QBTC_L (Section 8.2.2.17.90). |
| RESERVED | 31:4   | 0x0   | RSV  | Reserved.                                                                                                                |

### 8.2.2.17.92 Switch Security Violation Packet Count - SSVPC (0x00008780)

| Field | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------|--------|-------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SSVPC | 31:0   | 0x0   | RC   | <b>Switch Security Violation Packet Count</b><br>This register counts all Tx packets dropped. For example, packets dropped due to switch security violations such as SA or VLAN anti-spoof filtering, or packet that has (inner) VLAN that contradicts with PFVMVIR register definitions. Valid only in VMDq or IOV mode.<br>This counter includes also traffic sent to the BMC and blocked due to security violations. or packets dropped due to malicious events detection. |

### 8.2.2.17.93 FCoE Packets Transmitted Count - FCOEPTC (0x00008784)

| Field | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                             |
|-------|--------|-------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PTC   | 31:0   | 0x0   | RC   | <b>Packets Transmitted Count</b><br>Number of FCoE packets transmitted.<br>The counter does not include packets dropped due to anti-spoofing filtering or VLAN tag validation. This rule is applicable if FCoE traffic is sent by a VF. |

### 8.2.2.17.94 FCoE Dword Transmitted Count - FCOEDWTC (0x00008788)

| Field | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                |
|-------|--------|-------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DWTC  | 31:0   | 0x0   | RC   | <b>Dword Transmitted Count</b><br>Number of Dwords count in transmitted packets.<br>The counter relates to FCoE packets starting at the FC header up to and including the FC CRC (it excludes the Ethernet encapsulation). |

### 8.2.2.17.95 DMA Good Tx Packet Counter - TXDGPC (0x000087A0)

| Field | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                 |
|-------|--------|-------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GPTC  | 31:0   | 0x0   | RC   | <b>Good Packets Transmitted Count</b><br>Number of Tx packets from host memory.<br>This counter includes packets that are transmitted to the external network as well as packets that are transmitted only to local VMs. The later occurs only in VT mode when the local switch is enabled. Dropped packets counted in SSVPC register are not counted here. |

### 8.2.2.17.96 DMA Good Tx Byte Counter Low - TXDGBCL (0x000087A4)

| Field | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                     |
|-------|--------|-------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BCL   | 31:0   | 0x0   | RC   | <b>Byte Counter Low</b><br>The low 32 bits of the 36-bit byte counter of the Tx packets that match the TXDGPC register (Section 8.2.2.17.95).<br>The counter counts all bytes posted by the host and the VLAN (if bytes are added by hardware). Dropped packets counted in SSVPC register are not counted here. |

### 8.2.2.17.97 DMA Good Tx Byte Counter High - TXDGBCH (0x000087A8)

| Field    | Bit(s) | Init. | Type | Description                                                                                                                    |
|----------|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------------|
| BCH      | 3:0    | 0x0   | RC   | <b>Byte Counter High</b><br>High 4 bits of the 36-bit byte counter associated with the TXDGBCL register (Section 8.2.2.17.96). |
| RESERVED | 31:4   | 0x0   | RSV  | Reserved.                                                                                                                      |

### 8.2.2.17.98 OS2BMC Packets Transmitted by Host - O2BSPC (0x000087B0)

| Field | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------|--------|-------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| O2BPC | 31:0   | 0x0   | RC   | <b>OS-to-BMC Packet Count</b><br>OS2BMC packets transmitted count.<br>Counts the total number of packets originating from the functions that were sent to the manageability path. This includes packets received by the BMC and packet dropped in the X550 due to congestion conditions or due to anti-spoof check.<br>Counter is cleared when read by driver. Counter is also cleared by PCIe reset and software reset. When reaching maximum value counter does not wrap-around. |

## 8.2.2.18 Wake-Up and Proxy Control Registers

### 8.2.2.18.1 Wake-Up Control Register - WUC (0x00005800)

The *PME\_EN* and *PME\_STATUS* bits are reset when LAN\_PWR\_GOOD is 0. When AUX\_PWR=0, these bits are also reset by the assertion of PE\_RST\_N.

| Field      | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                           |

### 8.2.2.18.2 Wake-Up Filter Control Register - WUFC (0x00005808)

This register is used to enable each of the pre-defined and flexible filters for wake-up support. A value of 1b means the filter is turned on, and a value of 0b means the filter is turned off.

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                 |

### 8.2.2.18.3 Wake-Up Status Register - WUS (0x00005810)

This register is used to record statistics about all wake-up packets received. If a packet matches multiple criteria, multiple bits are set by hardware. Software writing a 1b to any bit clears that bit.

This register is not cleared when PE\_RST\_N is asserted. It is only cleared when LAN\_PWR\_GOOD is de-asserted, or when cleared by the driver.

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                       |

#### 8.2.2.18.5 IPv4 Address Table - IP4AT[n] (0x00005840 + 0x8\*n, n=0...3)

4 x IPv4 addresses for ARP/IPv4 Request packet and Directed IPv4 packet wake-up. IPv4[0] is loaded from MIPAF words in the NVM.

| Field    | Bit(s) | Init. | Type | Description                                                 |
|----------|--------|-------|------|-------------------------------------------------------------|
| IPV4ADDR | 31:0   | X     | RW   | <b>IPv4 Address</b><br>IPv4 Address 'n', where 'n' = 0...3. |

#### 8.2.2.18.6 IPv6 Address Table - IP6AT[n] (0x00005880 + 0x4\*n, n=0...3)

First IPv6 addresses for Neighbor Discovery packet filtering and Directed IPv6 packet wake-up.

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                         |
|----------|--------|-------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IPV6ADDR | 31:0   | X     | RW   | <b>IPv6 Address</b><br>4 x Register IPv6 filter. Register 'n' contains bytes '4*n' up to '4*n+3' of the IPv6 address. LS byte of register '0' is first on the wire. |

### 8.2.2.18.7 Wake-Up Packet Length - WUPL (0x00005900)

This register is de-featured and software should not access it (read or write).

### 8.2.2.18.8 IPv6 Address Table Extended - IP6AT\_EXT[n] (0x00005990 + 0x4\*n, n=0...11)

3 x IPv6 addresses for Neighbor Discovery packet filtering.

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                         |
|----------|--------|-------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IPV6ADDR | 31:0   | X     | RW   | <b>IPv6 Address</b><br>4 x Register IPv6 filter. Register 'n' contains bytes '4*n' up to '4*n+3' of the IPv6 address. LS byte of register '0' is first on the wire. |

### 8.2.2.18.9 Wake-Up Packet Memory (128 Bytes) - WUPM[n] (0x00005A00 + 0x4\*n, n=0...31)

| Field | Bit(s) | Init. | Type | Description                                                                                                                                                                                                            |
|-------|--------|-------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WUPD  | 31:0   | X     | RO   | <b>Wake-Up Packet Data</b><br>This register is used to store the first 128 bytes of the wake-up packet for software retrieval after the system wakes up. It should not be cleared by any reset including master reset. |

### 8.2.2.18.10 Proxying Status Register - PROXYS (0x00005F60)

This register is used to record statistics about all proxying packets received. If a packet matches multiple criteria, multiple bits could be set. Writing a 1b to any bit clears that bit.

This register is not cleared when RST# is asserted. It is only cleared when LAN\_PWR\_GOOD is de-asserted, or when cleared by the software device driver.

**Note:** If additional packets are received that match one of the wake-up filters, after the original wake-up packet is received, the PROXYS register is updated with the matching filters accordingly.

| Field        | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                       |

### 8.2.2.18.11 Proxying Filter Control Register - PROXYFC (0x00005F64)

This register is used to enable each of the pre-defined filters for Proxying support. This register is not cleared when RST# is asserted. It is only cleared when LAN\_PWR\_GOOD is de-asserted, or when cleared by the software device driver.

#### 8.2.2.18.12 Filter DW Even - FHFT\_FILTER\_DW\_EVEN[n,m] (0x00009000 + 0x10\*n + 0x100\*m, n=0...15, m=0...3 and 0x00009600 + 0x10\*(n-16) + 0x100\*m, n=16...31, m=0...3)

##### Notes:

- The mask field must be 8 bytes aligned even if the length field is not 8 bytes aligned, as hardware implementation compares 8 bytes at a time. Therefore, it should get extra masks until the end of the next quad word. Any mask bit that is located after the length should be set to 0b, indicating no comparison should be done.
- In case the actual length defined by the length field register and the mask bits is not 8 bytes aligned, there might be a case that a packet which is shorter than the actual required length passes the flexible filter. This might happen due to comparison of up to 7 bytes that come after the packet, but are not a real part of the packet.
- The last DW of each filter contains a length field defining the number of bytes from the beginning of the packet compared by this filter. If actual packet length is less than length specified by this field, the filter fails. Otherwise, it depends on the result of actual byte comparison. The value should not be greater than 128.

## 8.2.2.19 Management Filters Registers

The Management Filters registers are RO for the host. These registers are initialized at LAN Power Good and can be loaded from the NVM by the manageability firmware.

### 8.2.2.19.1 Management VLAN TAG Value - MAVTV[n] (0x00005010 + 0x4\*n, n=0...7)

| Field    | Bit(s) | Init. | Type | Description                                                                              |
|----------|--------|-------|------|------------------------------------------------------------------------------------------|
| VID      | 11:0   | 0x0   | RW   | <b>VLAN ID</b><br>Contains the VLAN ID that should be compared with the incoming packet. |
| RESERVED | 31:12  | 0x0   | RSV  | Reserved.                                                                                |

### 8.2.2.19.2 Management Flex UDP/TCP Ports - MFUTP[n] (0x00005030 + 0x4\*n, n=0...7)

**Note:** Each 32-bit register (n=0,...,7) refers to two port filters (register 0 refers to ports 0 and 1, register 2 refers to ports 2 and 3, etc.). SCTP packets do not match the MFUTP filters. MFUTP filters are programmed in Network order.

| Field      | Bit(s) | Init. | Type | Description                                                                         |
|------------|--------|-------|------|-------------------------------------------------------------------------------------|
| MFUTP_2N   | 15:0   | 0x0   | RW   | <b>Management Flex UDP/TCP Port 2n</b><br>(2n)-th Management Flex UDP/TCP port.     |
| MFUTP_2N_1 | 31:16  | 0x0   | RW   | <b>Management Flex UDP/TCP Port 2n+1</b><br>(2n+1)-th Management Flex UDP/TCP port. |

### 8.2.2.19.3 BMC IP Address Register - BMCIP[n] (0x00005050 + 0x4\*n, n=0...3)

These registers contain the BMC IP Address table.

| Field  | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                |
|--------|--------|-------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IPADDR | 31:0   | 0x0   | RW   | <b>IP Address</b><br>4 bytes of 16-bytes destination IP Address of the BMC.<br><ul style="list-style-type: none"> <li>n=0 contains the MSB for an IPv6 IP Address.</li> <li>n=3 contains an IPv4 IP Address or the LSB for an IPv6 IP Address.</li> </ul> For an IPv4 address, BMCIP 0...2 must be written with zeros.<br><b>Note:</b> This field is defined in Big Endian (LS byte is first on the wire). |

#### 8.2.2.19.4 BMC IP Valid Register - BMCIPVAL (0x00005060)

This register indicates the type of IP Address stored in the IPVAL register, and indicates if a valid address is stored.

| Field        | Bit(s) | Init. | Type | Description                                                                                             |

| RESERVED | 31:16  | 0x0   | RSV  | Reserved. Reads as 0. Ignored on write.                                                                                                                                                    |

### 8.2.2.19.13 FTFT Filter DW Even words - FTFT\_FILTER\_EVEN[n] (0x00009400 + 0x10\*n, n=0...15)

The Flexible TCO Filter Table registers (FTFT) contains a 128-byte pattern and a corresponding 128-bit mask array. If enabled, the first 128 bytes of the received packet are compared against the non-masked bytes in the FTFT register.

Each 128-byte filter is composed of 32 DW entries (FTFT\_FILTER\_ODD and FTFT\_FILTER\_EVEN), where each two DWs are accompanied by an 8-bit mask (FTFT\_FILTER\_MASK), one bit per filter byte. The mask field is set so that bit 0 in the mask masks byte 0, bit 1 masks byte 1, and so on. A value of 1 in the mask field means that the appropriate byte in the filter should be compared to the appropriate byte in the incoming packet.

The FTFT\_FILTER\_LENGTH register indicates the number of bytes to compare.

#### Notes:

- The mask field must be 8 bytes aligned even if the length field is not 8 bytes aligned, as hardware implementation compares 8 bytes at a time. Therefore, it should get extra masks until the end of the next quad word. Any mask bit that is located after the length should be set to 0b, indicating no comparison should be done.

- In case the actual length defined by the length field register and the mask bits is not 8 bytes aligned, there might be a case that a packet which is shorter than the actual required length passes the flexible filter. This might happen due to comparison of up to 7 bytes that come after the packet, but are not a real part of the packet.
- The last DW of each filter contains a length field defining the number of bytes from the beginning of the packet compared by this filter. If actual packet length is less than length specified by this field, the filter fails. Otherwise, it depends on the result of actual byte comparison. The value should not be greater than 128.
- FTFT registers are configured by firmware.

| Field            | Bit(s) | Init. | Type | Description                                         |

## 8.2.2.20 Manageability (ARC Subsystem) HOST Interface Registers

Host interface to the ARC subsystem is described in the [Section 11.8, “Manageability Host Interface”](#).

### 8.2.2.20.1 Software Semaphore Register - SWSM (0x00010140)

**Note:** This register is shared by both LAN ports.

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------|--------|-------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SMBI     | 0      | 0b    | RW   | <b>Semaphore Bit</b><br>This bit is set by hardware when this register is read by the device driver (one of the two PCIe functions), and cleared when the host driver writes 0b to it.<br>The first time this register is read, the value is 0b. In the next read the value is 1b (hardware mechanism). The value remains 1b until the device driver clears it.<br>This bit can be used as a semaphore between the two device's drivers, and is cleared on PCIe reset. |
| RESERVED | 31:1   | 0x0   | RSV  | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

### 8.2.2.20.2 Firmware Semaphore Register - FWSM (0x00010148)

**Note:** This register is shared by both LAN ports. This register should be written only by the manageability firmware. The device driver should only read this register. The firmware ignores the NVM semaphore in operating system hung states. Bits[15:0] are cleared on firmware reset.

| Field                      | Bit(s) | Init. | Type | Description                                                                                                                                                                                                            |

### 8.2.2.20.3 Software-Firmware Synchronization - SW\_FW\_SYNC (0x00010160)

Each bit represents different software semaphore agreed between software and firmware as follows: Bits[4:0] and Bits[10:12] are owned by software, while Bits[9:5] and Bits[13:15] are owned by firmware. Hardware does not lock access to these bits.

**Note:** This register is shared by both LAN ports. For more details on software and firmware synchronization, see [Section 11.8.4](#).

| Field              | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## 8.2.2.22 Virtualization PF Registers

### 8.2.2.22.1 PF VFLR Events Clear - PFVFLREC[n] (0x00000700 + 0x4\*n, n=0...1)

| Field      | Bit(s) | Init. | Type | Description                                                                                                                                                               |
|------------|--------|-------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CLEAR_VFLE | 31:0   | 0x0   | RW1C | <b>Clear VLFR Events</b><br>When set, bit 'i' in register 'n' reflects an FLR event on VF# 32*n+i. These bits are accessible only to the PF and are cleared by writing 1. |

### 8.2.2.22.2 PF Mailbox Interrupt Causes Register - PFMBICR[n] (0x00000710 + 0x4\*n, n=0...3)

Each register handles 16 VFs as defined here.

| Field | Bit(s) | Init. | Type | Description                                                                                                                                                                                                            |
|-------|--------|-------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VFREQ | 15:0   | 0x0   | RW1C | <b>VF Requested</b><br>Each bit in the VFREQ field is set when VF number (16*n+j) wrote a message in its mailbox, where 'n' is the register index (n=0...3) and 'j' is the index of the bits in the VFREQ (j=0...15).  |
| VFACK | 31:16  | 0x0   | RW1C | <b>VF Acknowledged</b><br>Each bit in the VFACK field is set when VF number (16*n+j) acknowledged a PF message, where 'n' is the register index (n=0...3) and '16+j' is the index of the bits in the VFACK (j=0...15). |

### 8.2.2.22.3 PF Mailbox Interrupt Mask Register - PFMBIMR[n] (0x00000720 + 0x4\*n, n=0...1)

| Field | Bit(s) | Init.      | Type | Description                                                                                                        |
|-------|--------|------------|------|--------------------------------------------------------------------------------------------------------------------|
| VFIM  | 31:0   | 0xFFFFFFFF | RW   | <b>VF Interrupt Mask</b><br>Bit j - Mailbox indication from VF number (32*n+j) might cause an interrupt to the PF. |

### 8.2.2.22.4 PF Queue Drop Enable Register - PFQDE (0x00002F04)

| Field     | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                             |
|-----------|--------|-------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PFQDE     | 0      | 0b    | RW   | <b>PF Queue Drop Enable</b><br>Enable drop of packets from Rx queue <i>QUEUE_INDEX</i> . This bit overrides the <i>SRCTL.DROP_EN</i> bit (Section 8.2.2.9.5) of each queue. In other words, if either of the bits is set, a packet received when no descriptor is available is dropped. |
| HIDE_VLAN | 1      | 0b    | RW   | <b>Hide VLAN</b><br>If this bit is set, the <i>RXDCTL.VME</i> setting is ignored (Section 8.2.2.9.7), the VLAN is always stripped, a value of zero is written in the <i>RDESC.VLAN</i> tag and in the <i>RDESC.STATUS.VP</i> fields of the received descriptor.                         |
| STRIP_TAG | 2      | 0b    | RW   | <b>Strip Tag</b><br>If this bit is set, the E-tag is stripped from the packet.<br>If only one type of tag should be stripped, the other tag's EtherType should be invalidated using the <i>ETAG_ETYPE.VALID</i> field (Section 8.2.2.8.5).                                              |
| RESERVED  | 7:3    | 0x0   | RSV  | Reserved.                                                                                                                                                                                                                                                                               |

| Field       | Bit(s) | Init. | Type | Description                                                                                                                                                                                                              |
|-------------|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| QUEUE_INDEX | 14:8   | 0x0   | RW   | <b>Queue Index</b><br>Indicates the queue referenced upon <i>WE/RE</i> commands.                                                                                                                                         |

### 8.2.2.22.15 Last VM Misbehavior Cause - Tx - LVMMC\_TX (0x00008108)

Bits in this register define the cause for blocking the malicious queue that was reported in the LMVM\_TX.MALICIOUS\_QUEUE field (Section 8.2.2.22.17) when the DMATXCTL.MDP\_EN bit is set (Section 8.2.2.10.2). For details of the different bits, refer to Section 7.8.4.3, “Malicious Driver Detection”.

**Note:** Only the first malicious event is registered for each packet. Therefore, if a bit is not set, it does not mean that this event did not occur, only that another malicious behavior was detected first.

| Field         | Bit(s) | Init. | Type | Description                                                                                     |

#### 8.2.2.22.25 PF VM VLAN Pool Filter Bitmap - PFVLVFB[n] (0x0000F200 + 0x4\*n, n=0...127)

**Note:** Software should initialize these registers before transmit and receive are enabled.

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------|--------|-------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| POOL_ENA | 31:0   | X     | RW   | <b>Pool Enable bit array</b><br>Each couple of registers '2*n' and '2*n+1' enables routing of packets that match a PFVLVF[n] filter to a Pool list (see <a href="#">Section 8.2.2.22.24</a> ).<br>Each bit when set, enables packet reception with the associated Pools as follows: <ul style="list-style-type: none"> <li>Bit 'i' in register '2*n' is associated with POOL 'i'.</li> <li>Bit 'i' in register '2*n+1' is associated with POOL '32+i'.</li> </ul> |

#### 8.2.2.22.26 PF Unicast Table Array - PFUTA[n] (0x0000F400 + 0x4\*n, n=0...127)

There is one register per 32 bits of the Unicast Address Table for a total of 128 registers (the PFUTA[127:0] designation). Software must mask to the desired bit on reads, and supply a 32-bit word on writes. The first bit of the address used to access the table is set according to the MCSTCTRL.MO field ([Section 8.2.2.8.7](#)). The 7 MS bits of the Ethernet MAC Address (out of the 12 bits) selects the register index, while the 5 LS bits (out of the 12 bits) selects the bit within a register.

**Note:** All accesses to this table must be 32 bit. The lookup algorithm is the same one used for the MTA table. This table should be zeroed by software before start of work.

| Field      | Bit(s) | Init. | Type | Description                                                                                                   |
|------------|--------|-------|------|---------------------------------------------------------------------------------------------------------------|
| BIT_VECTOR | 31:0   | X     | RW   | <b>Bit Vector</b><br>Word wide bit vector specifying 32 bits in the unicast destination address filter table. |

### 8.2.2.22.27 PF Mirror Rule Control - PFMRECTL[n] (0x0000F600 + 0x4\*n, n=0...3)

This register defines mirroring rules for each of four destination pools.

| Field    | Bit(s) | Init. | Type | Description                                                                                                                          |
|----------|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------------------|
| VPME     | 0      | 0b    | RW   | <b>Virtual Pool Mirroring Enable</b><br>Enables mirroring of certain pools as defined in the PFMVRM registers (Section 8.2.2.22.29). |
| UPME     | 1      | 0b    | RW   | <b>Uplink Port Mirroring Enable</b><br>Enables mirroring of all traffic received from the network.                                   |
| DPME     | 2      | 0b    | RW   | <b>Downlink Port Mirroring Enable</b><br>Enables mirroring of all traffic transmitted to the network.                                |
| VLME     | 3      | 0b    | RW   | <b>VLAN Mirroring Enable</b><br>Enables mirroring of a set of given VLANs as defined in the PFMVLAN registers (Section 8.2.2.22.28). |
| RESERVED | 7:4    | 0x0   | RSV  | Reserved.                                                                                                                            |
| MP       | 13:8   | 0x0   | RW   | <b>Mirror Pool</b><br>Defines the destination pool for this mirror rule.                                                             |
| RESERVED | 31:14  | 0x0   | RSV  | Reserved.                                                                                                                            |

### 8.2.2.22.28 PF Mirror Rule VLAN - PFMVLAN[n] (0x0000F610 + 0x4\*n, n=0...7)

This register defines the VLAN values as listed in the PFVLVF table (Section 8.2.2.22.24) taking part in the VLAN mirror rule. Registers 0 and 4 correspond to rule 0, registers 1 and 5 correspond to rule 1, etc. Registers 0..3 correspond to the LSB in the PFVLVF table (e.g. register 0 corresponds to VLAN filters 31:0, while register 4 corresponds to VLAN filters 63:32).

| Field | Bit(s) | Init. | Type | Description                                                               |
|-------|--------|-------|------|---------------------------------------------------------------------------|
| VLAN  | 31:0   | 0x0   | RW   | <b>VLAN</b><br>Bitmap listing which VLANs participate in the mirror rule. |

### 8.2.2.22.29 PF Mirror Rule Pool - PFMVRM[n] (0x0000F630 + 0x4\*n, n=0...7)

This register defines which pools are being mirrored to the destination pool. Registers 0 and 4 correspond to rule 0, registers 1 and 5 correspond to rule 1, etc. Registers 0..3 correspond to the LSB in the pool list (e.g. register 0 corresponds to pools 31:0, while register 4 corresponds to pools 63:32).

| Field | Bit(s) | Init. | Type | Description                                                               |
|-------|--------|-------|------|---------------------------------------------------------------------------|
| POOL  | 31:0   | 0x0   | RW   | <b>Pool</b><br>Bitmap listing which pools participate in the mirror rule. |

### 8.2.2.22.30 PF VM Tag Insert Register - PFVMTIR[n] (0x00017000 + 0x4\*n, n=0...63)

| Field       | Bit(s) | Init. | Type | Description                                                                                          |

### 8.2.2.23.4 EEE Tx LPI Count - TLPIC (0x000041F4)

This register counts EEE Tx LPI entry events. A EEE Tx LPI event occurs when the transmitter enters EEE (IEEE802.3az) LPI state. This register only increments if transmits are enabled and EEE operation is enabled.

| Field  | Bit(s) | Init. | Type | Description                                                                                                                             |
|--------|--------|-------|------|-----------------------------------------------------------------------------------------------------------------------------------------|
| ETLPIC | 31:0   | 0x0   | RC   | <b>EEE Transmit LPI Count</b><br>Number of EEE Tx LPI events.<br>Register cleared on read. Register does not wrap around at 0xFFFFFFFF. |

### 8.2.2.23.5 EEE Rx LPI Count - RLPIC (0x000041F8)

This register counts EEE Rx LPI entry events. A EEE Rx LPI event occurs when the receiver detects link partner entry into EEE (IEEE802.3az) LPI state. This register only increments if receives are enabled and EEE operation is enabled.

| Field  | Bit(s) | Init. | Type | Description                                                                                                                            |
|--------|--------|-------|------|----------------------------------------------------------------------------------------------------------------------------------------|

## 8.2.2.24 Security Registers

Security registers are mainly concerned with the internal settings of the AES crypto engine used by IPsec. They are owned by the PF in an IOV mode.

### 8.2.2.24.1 Security Tx Control - SECTXCTRL (0x00008800)

| Field         | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------|--------|-------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SECTX_DIS     | 0      | 1b    | RW   | <b>Security Transmit Disable</b><br>Tx security offload disable bit.<br>0b = The AES crypto engine used in Tx by LinkSec or IPsec offload is enabled. Normal operating mode when a security off load is enabled.<br>1b = The AES crypto engine used in Tx by LinkSec and IPsec offloads is disabled. This mode must be used to save the X550's power consumption when no security offload is enabled.<br>This bit is RW/RO if fused-off.                                  |
| TX_DIS        | 1      | 0b    | RW   | <b>Transmit Disable</b><br>Disable security Tx path.<br>0b = Tx data path is enabled. Normal operating mode.<br>1b = No new packet is fetched out from the Tx Packet Buffers, so that the Tx Security block can be internally emptied prior to changing the security mode. The SECTXSTAT.SECTX_RDY bit is de-asserted until the path is emptied by hardware (see <a href="#">Section 8.2.2.24.2</a> ).                                                                    |
| STORE_FORWARD | 2      | 0b    | RW   | <b>Store and Forward</b><br>Tx security buffer mode.<br>0b = Tx sec buffer is operated in pass-through mode. Operating mode when LinkSec is enabled or when no security off load is enabled.<br>1b = A complete frame is stored in the internal security Tx buffer prior to being forwarded to the MAC. Operating mode when IPsec off load is enabled (as requested to overwrite ICV field in AH frames). Note that it increases the Tx internal latencies (for all TCs). |

## 8.2.2.25 IPsec Registers

IPsec registers are owned by the PF in an IOV mode. There is no added value here to encrypt the SA contents when being read by software, because the SA contents is available in clear text from system memory, like for any IPsec flow handled in software.

### 8.2.2.25.1 IPsec Tx Index - IPSTXIDX (0x00008900)

**Notes:** *WRITE* and *READ* bits must not be set at the same time by software.

*IPS\_TX\_EN* is RW, but it is RO if fused-off and/or if *SECTXCTRL.SECTX\_DIS* is set to 1b.

| Field     | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                              |

### 8.2.2.25.2 IPsec Tx Salt Register - IPSTXSALT (0x00008904)

| Field        | Bit(s) | Init. | Type | Description                                                                                                          |
|--------------|--------|-------|------|----------------------------------------------------------------------------------------------------------------------|
| AES_128_SALT | 31:0   | 0x0   | RW   | <b>AEA 128 Salt</b><br>4 bytes salt that has been read/written from/to the Tx SA entry pointed to by <i>SA_IDX</i> . |

### 8.2.2.25.3 IPsec Tx Key Registers - IPSTXKEY[n] (0x00008908 + 0x4\*n, n=0...3)

| Field       | Bit(s) | Init. | Type | Description                                                                                                                                                                                             |
|-------------|--------|-------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AES_128_KEY | 31:0   | 0x0   | RW   | <b>AES 128 Key</b><br>4 bytes of a 16-byte key that has been read/written from/to the Tx SA entry pointed to by <i>SA_IDX</i> .<br>n=0 contains the LSB of the key.<br>n=3 contains the MSB of the key. |

**8.2.2.25.4 IPsec Rx Index - IPSRXIDX (0x00008E00)**

**Notes:** *WRITE* and *READ* bits must not be set at the same time by software.

*IPS\_RX\_EN* is RW, but it is RO if fused-off and/or if *SECRXCTRL.SECRX\_DIS* is set to 1b.

Software is not allowed to write/read access registers that belong to different Rx SA tables without writing the *IPSRXIDX* register in between for setting the *WRITE/READ* bit. Refer to Rx SA tables access rules described in [Section 7.13.9](#).

Software should not make changes in the Rx SA tables while changing the *IPS\_RX\_EN* bit.

| Field     | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| READ      | 30     | 0b    | RW   | <b>READ command</b><br>When set, the contents of the Rx SA table entry as pointed to by the [ <i>TABLE</i> , <i>TB_IDX</i> ] fields is loaded into the corresponding registers. Immediately self-cleared by hardware once the entry contents have been loaded into the corresponding registers. For instance, if this bit is set together with <i>TABLE</i> =10b and <i>TB_IDX</i> =0x9, the SPI value stored in entry 9 is loaded into the <i>IPSRXSPI</i> 0...3 registers. Rx SA registers related to another Rx SA table (e.g. <i>IPSRXKEY</i> 0...3 registers) must not be read when <i>TABLE</i> =01b. |
| WRITE     | 31     | 0b    | RW   | <b>WRITE command</b><br>When set, the contents of the registers concerned by the Rx SA table pointed to by the <i>TABLE</i> field is loaded into the table entry pointed to by the <i>TB_IDX</i> field. Immediately self-cleared by hardware once the entry contents have been loaded into the memory. For instance, if this bit is set together with <i>TABLE</i> =10b and <i>TB_IDX</i> =0x9, the value written in <i>IPSRXSPI</i> 0...3 registers is loaded into the SPI table entry 9.                                                                                                                  |

**8.2.2.25.5 IPsec Rx IP Address Register - IPSRXIPADDR[n] (0x00008E04 + 0x4\*n, n=0...3)**

These registers are related to the IP Address table.

| Field  | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                        |
|--------|--------|-------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IPADDR | 31:0   | 0x0   | RW   | <b>IP Address</b><br>4 bytes of 16-byte destination IP Address for the associated Rx SA(s).<br>n=0 contains the MSB for an IPv6 IP Address.<br>n=3 contains an IPv4 IP Address or the LSB for an IPv6 IP Address.<br>For an IPv4 address, <i>IPSRXIPADDR</i> 0...2 must be written with zeros.<br><b>Note:</b> This field is defined in Big Endian (LS byte is first on the wire). |

### 8.2.2.25.6 IPsec Rx SPI Register - IPSRXSPI (0x00008E14)

This register is related to the Rx SPI table.

| Field | Bit(s) | Init. | Type | Description                                                                                                                    |
|-------|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------------|
| SPI   | 31:0   | 0x0   | RW   | <b>SPI</b><br>SPI field for the SPI entry.<br><i>Note:</i> This field is defined in Big Endian (LS byte is first on the wire). |

### 8.2.2.25.7 IPsec Rx SPI Register IP Index - IPSRXIPIDX (0x00008E18)

This register is related to the Rx SPI table.

| Field    | Bit(s) | Init. | Type | Description                                                                                                              |
|----------|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------|
| IP_IDX   | 6:0    | 0x0   | RW   | <b>IP Index</b><br>Index in the IP Address table where the destination IP Address associated to that SPI entry is found. |
| RESERVED | 31:7   | 0x0   | RSV  | Reserved.                                                                                                                |

### 8.2.2.25.8 IPsec Rx Key Register - IPSRXKEY[n] (0x00008E1C + 0x4\*n, n=0...3)

These registers are related to the Rx KEY table.

| Field       | Bit(s) | Init. | Type | Description                                                                                                                            |
|-------------|--------|-------|------|----------------------------------------------------------------------------------------------------------------------------------------|
| AES_128_KEY | 31:0   | 0x0   | RW   | <b>AES 128 Key</b><br>4 bytes of 16-byte key of the KEY entry.<br>n=0 contains the LSB of the key.<br>n=3 contains the MSB of the key. |

### 8.2.2.25.9 IPsec Rx Salt Register - IPSRXSALT (0x00008E2C)

This register is related to the Rx KEY table.

| Field        | Bit(s) | Init. | Type | Description                                                      |
|--------------|--------|-------|------|------------------------------------------------------------------|
| AES_128_SALT | 31:0   | 0x0   | RW   | <b>AES 128 Salt</b><br>4 bytes salt associated to the KEY entry. |

### 8.2.2.25.10 IPsec Rx Mode Register - IPSRXMOD (0x00008E30)

This register is related to the Rx KEY table.

| Field    | Bit(s) | Init. | Type | Description                                                                          |
|----------|--------|-------|------|--------------------------------------------------------------------------------------|
| VALID    | 0      | 0b    | RW   | <b>Valid bit</b><br>0b = The KEY entry is not valid.<br>1b = The KEY entry is valid. |
| RESERVED | 1      | 0b    | RSV  | Reserved.                                                                            |

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                             |
|----------|--------|-------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PROTO    | 2      | 0b    | RW   | <b>IPsec Protocol select</b><br>0b = The KEY entry off-loads AH packets.<br>1b = The KEY entry off-loads ESP packets.                                                   |
| DECRYPT  | 3      | 0b    | RW   | <b>Decryption bit</b><br>When set, hardware performs decryption off load for this KEY entry.<br>Meaningful only if PROTO bit is set (i.e. ESP mode).                    |
| IPV6     | 4      | 0b    | RW   | <b>IPv6 type</b><br>When set, only matched IPv6 packet are off-loaded for that KEY entry.<br>When cleared, only matched IPv4 packets are off-loaded for that KEY entry. |
| RESERVED | 31:5   | 0x0   | RSV  | Reserved.                                                                                                                                                               |

## 8.2.2.26 VF Registers Mapping in the PF Space

### 8.2.2.26.1 VF Control Register - VFCTRL[n] (0x00000300 + 0x4\*n, n=0...63; WO)

This register array is the mapping of the VFs VFCTRL registers.

Field definitions are the same as those defined in [Section 8.3.2.1.1](#).

### 8.2.2.26.2 VF Extended Interrupt Cause - VFEICR[n] (0x00000B00 + 0x4\*n, n=0...63; RC/W1C)

Field definitions are the same as those defined in [Section 8.3.2.2.1](#).

### 8.2.2.26.3 VF Extended Interrupt Cause Set - VFEICS[n] (0x00000C00 + 0x4\*n, n=0...63; WO)

Field definitions are the same as those defined in [Section 8.3.2.2.2](#).

### 8.2.2.26.4 VF Extended Interrupt Mask Set/Read - VFEIMS[n] (0x00000D00 + 0x4\*n, n=0...63; RWS)

Field definitions are the same as those defined in [Section 8.3.2.2.3](#).

### 8.2.2.26.5 VF Extended Interrupt Mask Clear - VFEIMC[n] (0x00000E00 + 0x4\*n, n=0...63; WO)

Field definitions are the same as those defined in [Section 8.3.2.2.4](#).

### 8.2.2.26.6 VF Good Packets Received Count - VFGPRC[n] (0x0000101C + 0x40\*n, n=0...63; RW)

PF mirror of the VFGPRC register.

Field definitions are the same as those defined in [Section 8.3.2.6.1](#).

### 8.2.2.26.7 VF Good Octets Received Count Low - VFGORC\_LSB[n] (0x00001020 + 0x40\*n, n=0...63; RW)

PF mirror of the VFGORC\_LSB register.

Field definitions are the same as those defined in [Section 8.3.2.6.2](#).

### 8.2.2.26.8 VF Multiple Receive Queues Command Register - VFMRQC[n] (0x00003400 + 0x4\*n, n=0...63; RW)

PF mirror of VFMRQC registers of the VFs.

Field definitions are the same as those defined in [Section 8.3.2.3.10](#).

#### **8.2.2.26.9 VF Mailbox - VFMAILBOX[n] (0x00004C00 + 0x4\*n, n=0...63; RW)**

This register array is the mapping of the VFMAILBOX registers of the VFs.

Field definitions are the same as those defined in [Section 8.3.2.1.5](#).

#### **8.2.2.26.10 VF Extended Interrupt Auto Mask Enable - VFEIAM[n] (0x00004D00 + 0x4\*n, n=0...63; RW)**

Field definitions are the same as those defined in [Section 8.3.2.2.5](#).

#### **8.2.2.26.11 VF Interrupt Vector Allocation Registers Misc - VFIVAR\_MISC[n] (0x00004E00 + 0x4\*n, n=0...63; RW)**

These registers map the mailbox interrupt into MSI-X vector (PF mirror). For more details, refer to [Section 7.3.4, "Mapping of Interrupt Causes"](#).

Field definitions are the same as those defined in [Section 8.3.2.2.7](#).

#### **8.2.2.26.12 VF Good Packets Transmitted Count - VFGPTC[n] (0x00008300 + 0x4\*n, n=0...63; RO)**

PF mirror of the VFGPTC register.

Field definitions are the same as those defined in [Section 8.3.2.6.5](#).

#### **8.2.2.26.13 VF Good Octets Transmitted Count LSB - VFGOTC\_LSB[n] (0x00008400 + 0x8\*n, n=0...63; RO)**

PF mirror of the VFGOTC\_LSB register.

Field definitions are the same as those defined in [Section 8.3.2.6.6](#).

#### **8.2.2.26.14 VF Good Octets Transmitted Count MSB - VFGOTC\_MSB[n] (0x00008404 + 0x8\*n, n=0...63; RO)**

PF mirror of the VFGOTC\_MSB register.

Field definitions are the same as those defined in [Section 8.3.2.6.7](#).

#### **8.2.2.26.15 VF Multicast Packets Received Count - VFMPRC[n] (0x0000D01C + 0x40\*n, n=0...63; RO)**

PF mirror of the VFMPRC register.

Field definitions are the same as those defined in [Section 8.3.2.6.4](#).

#### **8.2.2.26.16 VF Good Octets Received Count High - VFGORC\_MSB[n] (0x0000D020 + 0x40\*n, n=0...63; RW)**

PF mirror of the VFGORC\_MSB register.

Field definitions are the same as those defined in [Section 8.3.2.6.3](#).

#### **8.2.2.26.17 VF Interrupt Vector Allocation Registers - VFIVAR[n] (0x00012500 + 0x4\*n, n=0...63; RW)**

These registers map VF interrupt causes into MSI-X vectors (PF mirror). For more details, refer to [Section 7.3.4, "Mapping of Interrupt Causes"](#).

Field definitions are the same as those defined in [Section 8.3.2.2.6](#).

#### **8.2.2.26.18 PF Mailbox Memory - PFMBMEM[n,m] (0x00013000 + 0x4\*n + 0x40\*m, n=0...15, m=0...63; RW)**

Mailbox Memory for PF and VF Driver Communications. The mailbox size for each VM is 64 bytes accessed by 16 x 32-bit registers. Locations can be accessed as 32- or 64-bit words. This is the mapping of this memory in the PF space.

Field definitions are the same as those defined in [Section 8.3.2.1.4](#).

## 8.2.3 BAR3 Registers Summary

Table 8-5. BAR3 Registers Summary

| Offset / Alias Offset          | Abbreviation | Name                             | Page |
|--------------------------------|--------------|----------------------------------|------|
| <b>MSI-X Table Registers</b>   |              |                                  |      |
| 0x00000000 + 0x10*n, n=0...255 | MSIXTADD[n]  | MSI-X Table Entry Lower Address  | 674  |
| 0x00000004 + 0x10*n, n=0...255 | MSIXTUADD[n] | MSI-X Table Entry Upper Address  | 674  |
| 0x00000008 + 0x10*n, n=0...255 | MSIXTMSG[n]  | MSI-X Table Entry Message        | 675  |
| 0x0000000C + 0x10*n, n=0...255 | MSIXVCTRL[n] | MSI-X Table Entry Vector Control | 675  |
| 0x00002000 + 0x4*n, n=0...7    | MSIXPBA[n]   | MSIXPBA Bit Description          | 675  |

## 8.2.4 Detailed Register Description - PF BAR3

### 8.2.4.1 MSI-X Table Registers

The MSI-X capability is described in [Section 9.2.3.3](#). The MSI-X table is described in [Section 9.2.3.3.4](#) and the Pending Bit Array (PBA) is described in [Section 9.2.3.3.5](#). These registers are located in the MSI-X BAR.

#### 8.2.4.1.1 MSI-X Table Entry Lower Address - MSIXTADD[n] (0x00000000 + 0x10\*n, n=0...255)

| Field      | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                    |
|------------|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MSIXTADD10 | 1:0    | 00b   | RW   | <b>Message Address 1:0</b><br>For proper Dword alignment, software must always write zeros to these two bits;. Otherwise, the result is undefined. The state of these bits after reset must be 0b. These bits are permitted to be read-only or read/write.                     |
| MSIXTADD   | 31:2   | 0x0   | RW   | <b>Message Address</b><br>System-specified message lower address.<br>For MSI-X messages, the contents of this field from an MSI-X table entry specifies the lower portion of the Dword-aligned address (AD[31:02]) for the memory write transaction. This field is read/write. |

#### 8.2.4.1.2 MSI-X Table Entry Upper Address - MSIXTUADD[n] (0x00000004 + 0x10\*n, n=0...255)

| Field     | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                           |
|-----------|--------|-------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MSIXTUADD | 31:0   | 0x0   | RW   | <b>Message Upper Address</b><br>System-specified message upper address bits.<br>If this field is zero, Single Address Cycle (SAC) messages are used. If this field is non-zero, Dual Address Cycle (DAC) messages are used. This field is read/write. |

### 8.2.4.1.3 MSI-X Table Entry Message - MSIXTMSG[n] (0x00000008 + 0x10\*n, n=0...255)

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                         |
|----------|--------|-------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MSIXTMSG | 31:0   | 0x0   | RW   | <b>Message Data</b><br>System-specified message data.<br>For MSI-X messages, the contents of this field from an MSI-X table entry specifies the data driven on AD[31:0] during the memory write transaction's data phase. This field is read/write. |

### 8.2.4.1.4 MSI-X Table Entry Vector Control - MSIXVCTRL[n] (0x0000000C + 0x10\*n, n=0...255)

| Field     | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                      |
|-----------|--------|-------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MSIXVCTRL | 0      | 1b    | RW   | <b>Mask Bit</b><br>When this bit is set, the function is prohibited from sending a message using this MSI-X table entry. However, any other MSI-X table entries programmed with the same vector are still capable of sending an equivalent message unless they are also masked.<br>This bit's state after reset is 1b (entry is masked). This bit is read/write. |
| RESERVED  | 31:1   | 0x0   | RSV  | Reserved.<br>After reset, the state of these bits must be 0b. However, for potential future use, software must preserve the value of these reserved bits when modifying the value of other Vector Control bits. If software modifies the value of these reserved bits, the result is undefined.                                                                  |

### 8.2.4.1.5 MSIXPBA Bit Description - MSIXPBA[n] (0x00002000 + 0x4\*n, n=0...7)

**Note:** Registers 2...7 are usable only by the VFs in IOV mode. These registers are not exposed to the operating system by the *Table Size* field in the *MSI-X Message Control* word.

| Field  | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                             |
|--------|--------|-------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PENBIT | 31:0   | 0x0   | RO   | <b>MSI-X Pending Bits</b><br>Each bit is set to 1b when the appropriate interrupt request is set, and cleared to 0b when the appropriate interrupt request is cleared. Bit 'i' in register 'N' is associated with MSI-X vector 32*N+i, where N = 0...3. |

## 8.3 Device Registers - VF

### 8.3.1 BAR0 Registers Summary

Table 8-6. BAR0 Registers Summary

| Offset / Alias Offset                 | Abbreviation | Name                                               | Page |
|---------------------------------------|--------------|----------------------------------------------------|------|
| <b>General Control Registers - VF</b> |              |                                                    |      |
| 0x00000000                            | VFCTRL       | VF Control Register                                | 678  |
| 0x00000008                            | VFSTATUS     | VF Device Status Register                          | 678  |
| 0x00000010                            | VFLINKS      | Link Status Register                               | 678  |
| 0x00000200 + 0x4*n, n=0...15          | VFMBMEM[n]   | VF Mailbox Memory                                  | 678  |
| 0x000002FC                            | VFMAILBOX    | VF Mailbox                                         | 678  |
| <b>Interrupt Registers - VF</b>       |              |                                                    |      |
| 0x00000100                            | VFEICR       | VF Extended Interrupt Cause                        | 679  |
| 0x00000104                            | VFEICS       | VF Extended Interrupt Cause Set                    | 679  |
| 0x00000108                            | VFEIMS       | VF Extended Interrupt Mask Set/Read                | 679  |
| 0x0000010C                            | VFEIMC       | VF Extended Interrupt Mask Clear                   | 680  |
| 0x00000114                            | VFEIAM       | VF Extended Interrupt Auto Mask Enable             | 680  |
| 0x00000120 + 0x4*n, n=0...3           | VFIVAR[n]    | VF Interrupt Vector Allocation Registers           | 680  |
| 0x00000140                            | VFIVAR_MISC  | VF Interrupt Vector Allocation Registers Misc      | 681  |
| 0x00000148                            | VFPBACL      | VF MSI-X PBA Clear                                 | 681  |
| 0x00000180 + 0x4*n, n=0...1           | VFRSCINT[n]  | VF RSC Enable Interrupt                            | 681  |
| 0x00000820 + 0x4*n, n=0...1           | VFEITR[n]    | VF Extended Interrupt Throttle Registers           | 681  |
| <b>Receive Registers - VF</b>         |              |                                                    |      |
| 0x00000300                            | VFPSRTYPE    | VF Replication Packet Split Receive Type Register  | 681  |
| 0x00001000 + 0x40*n, n=0...7          | VFRDBAL[n]   | VF Receive Descriptor Base Address Low             | 681  |
| 0x00001004 + 0x40*n, n=0...7          | VFRDBAH[n]   | VF Receive Descriptor Base Address High            | 682  |
| 0x00001008 + 0x40*n, n=0...7          | VFRDLEN[n]   | VF Receive Descriptor Length                       | 682  |
| 0x00001010 + 0x40*n, n=0...7          | VFRDH[n]     | VF Receive Descriptor Head                         | 682  |
| 0x00001014 + 0x40*n, n=0...7          | VFSRRCTL[n]  | VF Split and Replication Receive Control Registers | 682  |
| 0x00001018 + 0x40*n, n=0...7          | VFRDT[n]     | VF Receive Descriptor Tail                         | 682  |
| 0x00001028 + 0x40*n, n=0...7          | VFRXDCTL[n]  | VF Receive Descriptor Control                      | 682  |
| 0x0000102C + 0x40*n, n=0...7          | VFRSCCTL[n]  | VF RSC Control                                     | 682  |
| 0x00003000                            | VFMRQC       | VF Multiple Receive Queues Command Register        | 682  |
| 0x00003100 + 0x4*n, n=0...9           | VFRSSRK[n]   | VF RSS Random Key Register                         | 683  |
| 0x00003200 + 0x4*n, n=0...15          | VFRETA[n]    | VF Redirection Table                               | 683  |

**Table 8-6. BAR0 Registers Summary (Continued)**

| Offset / Alias Offset                       | Abbreviation    | Name                                                | Page |
|---------------------------------------------|-----------------|-----------------------------------------------------|------|
| <b>Transmit Registers - VF</b>              |                 |                                                     |      |

## 8.3.2 Detailed Register Description - VF BAR0

### 8.3.2.1 General Control Registers - VF

#### 8.3.2.1.1 VF Control Register - VFCTRL (0x00000000)

| Field    | Bit(s) | Init. | Type | Description                                                                                             |
|----------|--------|-------|------|---------------------------------------------------------------------------------------------------------|
| RESERVED | 25:0   | 0x0   | RSV  | Reserved.                                                                                               |
| RST      | 26     | 0b    | WO   | <b>VF Reset</b><br>This bit performs a reset of the queue enable and the interrupt registers of the VF. |
| RESERVED | 31:27  | 0x0   | RSV  | Reserved.                                                                                               |

#### 8.3.2.1.2 VF Device Status Register - VFSTATUS (0x00000008; RO)

This register is a mirror of the PF status register.

Field definitions are the same as those defined in [Section 8.2.2.1.2](#).

#### 8.3.2.1.3 Link Status Register - VFLINKS (0x00000010; RO)

This register is the mapping of the PF's LINKS register.

Field definitions are the same as those defined in [Section 8.2.2.16.7](#).

#### 8.3.2.1.4 VF Mailbox Memory - VFMBMEM[n] (0x00000200 + 0x4\*n, n=0...15)

Mailbox Memory for PF and VF driver communications. The mailbox size for each VM is 64 bytes accessed by 16 x 32-bit registers. Locations can be accessed as 32- or 64-bit words.

| Field        | Bit(s) | Init. | Type | Description                                                               |
|--------------|--------|-------|------|---------------------------------------------------------------------------|
| MAILBOX_DATA | 31:0   | X     | RW   | <b>Mailbox Data</b><br>Mailbox data is composed of 16 x 4 byte registers. |

#### 8.3.2.1.5 VF Mailbox - VFMAILBOX (0x000002FC)

This register is cleared by VLFR (excluding the *RSTI* bit).

| Field | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                |
|-------|--------|-------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| REQ   | 0      | 0b    | WO   | <b>Request</b><br>Request for PF Ready.<br>Setting this bit, causes an interrupt to the PF. This bit always reads as 0b. Setting this bit sets the corresponding bit in the <i>VFREQ</i> field in PFMBICR register ( <a href="#">Section 8.2.2.22.2</a> ). |
| ACK   | 1      | 0b    | WO   | <b>Acknowledge</b><br>PF message received.<br>Setting this bit, causes an interrupt to the PF. This bit always reads as 0b. Setting this bit sets the corresponding bit in the <i>VFACK</i> field in PFMBICR register.                                     |

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                                                    |
|----------|--------|-------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VFU      | 2      | 0b    | RW   | <b>VFU</b><br>Buffer is taken by VF.<br>This bit can be set only if the <i>PFU</i> bit is cleared and is mirrored in the <i>VFU</i> bit of the <i>PFMAILBOX</i> register (Section 8.2.2.22.8). |
| PFU      | 3      | 0b    | RW   | <b>PFU</b><br>Buffer is taken by PF.<br>This bit is RO for the VF and is a mirror of the <i>PFU</i> bit of the <i>PFMAILBOX</i> register.                                                      |
| PFSTS    | 4      | 0b    | RC   | <b>PF Status</b><br>PF wrote a message in the mailbox.                                                                                                                                         |
| PFAK     | 5      | 0b    | RC   | <b>PF Acknowledge</b><br>PF acknowledged the VF previous message.                                                                                                                              |
| RSTI     | 6      | 1b    | RO   | <b>Reset Indication</b><br>Indicates that the PF reset the shared resources and the reset sequence is in progress. This bit is not affected by <i>VFLR</i> .                                   |
| RSTD     | 7      | 0b    | RC   | <b>Reset Done</b><br>Indicates that a PF software reset completed.                                                                                                                             |

## 8.3.2.2 Interrupt Registers - VF

### 8.3.2.2.1 VF Extended Interrupt Cause - VFEICR (0x00000100)

| Field    | Bit(s) | Init. | Type | Description                                                               |
|----------|--------|-------|------|---------------------------------------------------------------------------|
| MSIX     | 2:0    | 000b  | RW1C | <b>MSI-X</b><br>Indicates an interrupt cause mapped to MSI-X vectors 2:0. |
| RESERVED | 31:3   | 0x0   | RSV  | Reserved.                                                                 |

### 8.3.2.2.2 VF Extended Interrupt Cause Set - VFEICS (0x00000104)

| Field    | Bit(s) | Init. | Type | Description                                                              |
|----------|--------|-------|------|--------------------------------------------------------------------------|
| MSIX     | 2:0    | 000b  | WO   | <b>MSI-X</b><br>Sets to the corresponding EICR bit of MSI-X vectors 2:0. |
| RESERVED | 31:3   | 0x0   | RSV  | Reserved.                                                                |

### 8.3.2.2.3 VF Extended Interrupt Mask Set/Read - VFEIMS (0x00000108)

| Field    | Bit(s) | Init. | Type | Description                                                                            |
|----------|--------|-------|------|----------------------------------------------------------------------------------------|
| MSIX     | 2:0    | 000b  | RWS  | <b>MSI-X</b><br>Sets the Mask bit for the corresponding EICR bit of MSI-X vectors 2:0. |
| RESERVED | 31:3   | 0x0   | RSV  | Reserved.                                                                              |

#### 8.3.2.2.4 VF Extended Interrupt Mask Clear - VFEIMC (0x0000010C)

| Field    | Bit(s) | Init. | Type | Description                                                                              |
|----------|--------|-------|------|------------------------------------------------------------------------------------------|
| MSIX     | 2:0    | 000b  | WO   | <b>MSI-X</b><br>Clears the Mask bit for the corresponding EICR bit of MSI-X vectors 2:0. |
| RESERVED | 31:3   | 0x0   | RSV  | Reserved.                                                                                |

#### 8.3.2.2.5 VF Extended Interrupt Auto Mask Enable - VFEIAM (0x00000114)

| Field    | Bit(s) | Init. | Type | Description                                                                        |
|----------|--------|-------|------|------------------------------------------------------------------------------------|
| MSIX     | 2:0    | 000b  | RW   | <b>MSI-X</b><br>Auto-mask bit for the corresponding EICR bit of MSI-X vectors 2:0. |
| RESERVED | 31:3   | 0x0   | RSV  | Reserved.                                                                          |

#### 8.3.2.2.6 VF Interrupt Vector Allocation Registers - VFIVAR[n] (0x00000120 + 0x4\*n, n=0...3)

These registers map VF interrupt causes into MSI-X vectors. For more details, refer to [Section 7.3.4, “Mapping of Interrupt Causes”](#).

| Field           | Bit(s) | Init. | Type | Description                                                                                                                      |
|-----------------|--------|-------|------|----------------------------------------------------------------------------------------------------------------------------------|
| INT_ALLOC_0     | 0      | 0b    | RW   | <b>Interrupt Allocation 0</b><br>Defines the MSI-X vector (0 or 1) assigned to Rx queue '2*N' for IVAR 'N' register (N=0...3).   |
| RESERVED        | 6:1    | 0x0   | RSV  | Reserved.                                                                                                                        |
| INT_ALLOC_VAL_0 | 7      | 0b    | RW   | <b>Interrupt Allocation Valid 0</b><br>Valid bit for <i>INT_ALLOC</i> [0].                                                       |
| INT_ALLOC_1     | 8      | 0b    | RW   | <b>Interrupt Allocation 1</b><br>Defines the MSI-X vector (0 or 1) assigned to Tx queue '2*N' for IVAR 'N' register (N=0...3).   |
| RESERVED        | 14:9   | 0x0   | RSV  | Reserved.                                                                                                                        |
| INT_ALLOC_VAL_1 | 15     | 0b    | RW   | <b>Interrupt Allocation Valid 1</b><br>Valid bit for <i>INT_ALLOC</i> [1].                                                       |
| INT_ALLOC_2     | 16     | 0b    | RW   | <b>Interrupt Allocation 2</b><br>Defines the MSI-X vector (0 or 1) assigned to Rx queue '2*N+1' for IVAR 'N' register (N=0...3). |
| RESERVED        | 22:17  | 0x0   | RSV  | Reserved.                                                                                                                        |
| INT_ALLOC_VAL_2 | 23     | 0b    | RW   | <b>Interrupt Allocation Valid 2</b><br>Valid bit for <i>INT_ALLOC</i> [2].                                                       |
| INT_ALLOC_3     | 24     | 0b    | RW   | <b>Interrupt Allocation 3</b><br>Defines the MSI-X vector (0 or 1) assigned to Tx queue '2*N+1' for IVAR 'N' register (N=0...3). |
| RESERVED        | 30:25  | 0x0   | RSV  | Reserved.                                                                                                                        |
| INT_ALLOC_VAL_3 | 31     | 0b    | RW   | <b>Interrupt Allocation Valid 3</b><br>Valid bit for <i>INT_ALLOC</i> [3].                                                       |

### 8.3.2.2.7 VF Interrupt Vector Allocation Registers Misc - VFIVAR\_MISC (0x00000140)

This register maps the mailbox interrupt into MSI-X vector. For more details, refer to [Section 7.3.4, “Mapping of Interrupt Causes”](#).

| Field           | Bit(s) | Init. | Type | Description                                                                                  |
|-----------------|--------|-------|------|----------------------------------------------------------------------------------------------|
| INT_ALLOC_0     | 1:0    | X     | RW   | <b>Interrupt Allocation 0</b><br>Defines the MSI-X vector assigned to the mailbox interrupt. |
| RESERVED        | 6:2    | 0x0   | RSV  | Reserved.                                                                                    |
| INT_ALLOC_VAL_0 | 7      | 0b    | RW   | <b>Interrupt Allocation Valid 0</b><br>Valid bit for <i>INT_ALLOC</i> [0].                   |
| RESERVED        | 31:8   | 0x0   | RSV  | Reserved.                                                                                    |

### 8.3.2.2.8 VF MSI-X PBA Clear - VFPBACL (0x00000148)

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                                                                    |
|----------|--------|-------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PENBIT   | 2:0    | 0x0   | RW1C | <b>MSI-X Pending Bits Clear</b><br>MSI-X Pending Bits Clear.<br>Writing a 1b to any bit clears the corresponding <i>MSIXPBA</i> bit. Writing a 0b has no effect. Reading this register returns the PBA vector. |
| RESERVED | 31:3   | 0x0   | RSV  | Reserved.                                                                                                                                                                                                      |

### 8.3.2.2.9 VF RSC Enable Interrupt - VFRSCINT[n] (0x00000180 + 0x4\*n, n=0...1; RW)

Field definitions are the same as those defined in [Section 8.2.2.6.20](#).

### 8.3.2.2.10 VF Extended Interrupt Throttle Registers - VFEITR[n] (0x00000820 + 0x4\*n, n=0...1; RW)

Field definitions are the same as those defined in [Section 8.2.2.6.4](#).

## 8.3.2.3 Receive Registers - VF

### 8.3.2.3.1 VF Replication Packet Split Receive Type Register - VFPSRTYPE (0x00000300; RW)

Field definitions are the same as those defined in [Section 8.2.2.8.17](#).

### 8.3.2.3.2 VF Receive Descriptor Base Address Low - VFRDBAL[n] (0x00001000 + 0x40\*n, n=0...7; RW)

Field definitions are the same as those defined in [Section 8.2.2.9.1](#).

### 8.3.2.3.3 VF Receive Descriptor Base Address High - VFRDBAH[n] (0x00001004 + 0x40\*n, n=0...7; RW)

Field definitions are the same as those defined in [Section 8.2.2.9.2](#).

### 8.3.2.3.4 VF Receive Descriptor Length - VFRDLEN[n] (0x00001008 + 0x40\*n, n=0...7; RW)

Field definitions are the same as those defined in [Section 8.2.2.9.3](#).

### 8.3.2.3.5 VF Receive Descriptor Head - VFRDH[n] (0x00001010 + 0x40\*n, n=0...7; RO)

Field definitions are the same as those defined in [Section 8.2.2.9.4](#).

### 8.3.2.3.6 VF Split and Replication Receive Control Registers - VFSRRCTL[n] (0x00001014 + 0x40\*n, n=0...7; RW)

Field definitions are the same as those defined in [Section 8.2.2.9.5](#).

### 8.3.2.3.7 VF Receive Descriptor Tail - VFRDT[n] (0x00001018 + 0x40\*n, n=0...7; RW)

Field definitions are the same as those defined in [Section 8.2.2.9.6](#).

### 8.3.2.3.8 VF Receive Descriptor Control - VFRXDCTL[n] (0x00001028 + 0x40\*n, n=0...7; RW)

Field definitions are the same as those defined in [Section 8.2.2.9.7](#).

### 8.3.2.3.9 VF RSC Control - VFRSCCTL[n] (0x0000102C + 0x40\*n, n=0...7; RW)

Field definitions are the same as those defined in [Section 8.2.2.9.8](#).

### 8.3.2.3.10 VF Multiple Receive Queues Command Register - VFMRQC (0x00003000)

| Field | Bit(s) | Init. | Type | Description                                                                                                 |
|-------|--------|-------|------|-------------------------------------------------------------------------------------------------------------|
| RSSE  | 0      | 0b    | RW   | <b>RSS Enable</b><br>This bit enables the VF RSS mechanism.<br>0b = VF RSS disabled.<br>1b = VF RSS enable. |

| Field            | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

### 8.3.2.3.11 VF RSS Random Key Register - VFRSSRK[n] (0x00003100 + 0x4\*n, n=0...9; RW)

PF mirror of VFRSSK registers of the VFs.

Field definitions are the same as those defined in [Section 8.2.2.8.25](#).

### 8.3.2.3.12 VF Redirection Table - VFRETA[n] (0x00003200 + 0x4\*n, n=0...15; RW)

VF version of VFRETA registers. The redirection table has 64 entries in 16 registers.

Field definitions are the same as those defined in [Section 8.2.2.8.26](#).

## 8.3.2.4 Transmit Registers - VF

### 8.3.2.4.1 VF Transmit Descriptor Base Address Low - VFTDBAL[n] (0x00002000 + 0x40\*n, n=0...7; RW)

Field definitions are the same as those defined in [Section 8.2.2.10.5](#).

### 8.3.2.4.2 VF Transmit Descriptor Base Address High - VFTDBAH[n] (0x00002004 + 0x40\*n, n=0...7; RW)

Field definitions are the same as those defined in [Section 8.2.2.10.6](#).

### 8.3.2.4.3 VF Transmit Descriptor Length - VFTDLEN[n] (0x00002008 + 0x40\*n, n=0...7; RW)

Field definitions are the same as those defined in [Section 8.2.2.10.7](#).

#### **8.3.2.4.4 VF Transmit Descriptor Head - VFTDH[n] (0x00002010 + 0x40\*n, n=0...7; RO)**

Field definitions are the same as those defined in [Section 8.2.2.10.8](#).

#### **8.3.2.4.5 VF Transmit Descriptor Tail - VFTDT[n] (0x00002018 + 0x40\*n, n=0...7; RW)**

Field definitions are the same as those defined in [Section 8.2.2.10.9](#).

#### **8.3.2.4.6 VF Transmit Descriptor Control - VFTXDCTL[n] (0x00002028 + 0x40\*n, n=0...7; RW)**

Field definitions are the same as those defined in [Section 8.2.2.10.10](#).

#### **8.3.2.4.7 VF Tx Descriptor Completion Write Back Address Low - VFTDWBAL[n] (0x00002038 + 0x40\*n, n=0...7; RW)**

Field definitions are the same as those defined in [Section 8.2.2.10.11](#).

#### **8.3.2.4.8 VF Tx Descriptor Completion Write Back Address High - VFTDWBAH[n] (0x0000203C + 0x40\*n, n=0...7; RW)**

Field definitions are the same as those defined in [Section 8.2.2.10.12](#).

### **8.3.2.5 TPH Registers - VF**

#### **8.3.2.5.1 VF Rx TPH Control Register - VFTPH\_RXCTRL[n] (0x0000100C + 0x40\*n, n=0...7; RW)**

Field definitions are the same as those defined in [Section 8.2.2.12.1](#).

#### **8.3.2.5.2 VF Tx TPH Control Registers - VFTPH\_TXCTRL[n] (0x0000200C + 0x40\*n, n=0...7; RW)**

Field definitions are the same as those defined in [Section 8.2.2.12.3](#).

## 8.3.2.6 Statistic Register Descriptions - VF

Registers in this section are RO by VF and RW by PF. Statistics are reset by PF clearing the register.

### 8.3.2.6.1 VF Good Packets Received Count - VFGPRC (0x0000101C)

| Field  | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                              |
|--------|--------|-------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VFGPRC | 31:0   | 0x0   | RW   | <b>VF Good Packets Received Count</b><br>Number of good packets received for this VF (of any length). This counter includes loopback packets or replications of multicast packets. The counter is not cleared on read. Furthermore, the register is a cyclic counter incrementing from 0xFFFF to 0x0000. |

### 8.3.2.6.2 VF Good Octets Received Count Low - VFGORC\_LSB (0x00001020)

| Field      | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------|--------|-------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VFGORC_LSB | 31:0   | 0x0   | RW   | <b>VF Good Octets Received Count LSB</b><br>Number of good octets received (32 LSB of a 36-bit counter) by the queues allocated to this VF.<br>The counter includes loopback packets or replications of multicast packets. This register includes bytes received in a packet from the <i>Destination Address</i> field through the <i>CRC</i> field, inclusively. Octets are counted on the VF interface rather than on the network interface. For example, LinkSec octets are not counted. Bytes of RSC are counted before coalescing. The counter is not cleared on read. Furthermore, the register is a cyclic counter incrementing from 0xFFFF to 0x0000. |

### 8.3.2.6.3 VF Good Octets Received Count High - VFGORC\_MSB (0x00001024)

| Field      | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                         |
|------------|--------|-------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VFGORC_MSB | 3:0    | 0x0   | RW   | <b>VF Good Octets Received Count MSB</b><br>Number of good octets received (4 MSB of a 36-bit counter) by the queues allocated to this VF (see <a href="#">Section 8.3.2.6.2</a> for more details). The counter is not cleared on read. Furthermore, the register is a cyclic counter incrementing from 0xF to 0x0. |
| RESERVED   | 31:4   | 0x0   | RSV  | Reserved.                                                                                                                                                                                                                                                                                                           |

### 8.3.2.6.4 VF Multicast Packets Received Count - VFMPRC (0x00001034)

| Field  | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|--------|-------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VFMPRC | 31:0   | 0x0   | RO   | <b>VF Multicast Packets Received Count</b><br>Number of multicast good packets received by this VF (of any length) that pass the Ethernet MAC Address filtering (excluding broadcast packets). The counter does not count received flow control packets. This register increments only if receives are enabled. This register does not count packets counted by the Missed Packet Count (MPC) register. This counter also includes loopback packets or replications of multicast packets. The counter is not cleared on read. Furthermore, the register is a cyclic counter incrementing from 0xFFFF to 0x0000. |

### 8.3.2.6.5 VF Good Packets Transmitted Count - VFGPTC (0x0000201C)

| Field  | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------|--------|-------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VFGPTC | 31:0   | 0x0   | RO   | <b>VF Good Packets Transmitted Count</b><br>Number of good packets sent by the queues allocated to this VF.<br>A packet is considered as transmitted if it is forwarded to the MAC unit for transmission to the network and/or is accepted by the internal Tx to Rx switch enablement logic. Packets dropped due to anti-spoofing filtering or loopback packets that are rejected by the Tx to Rx switch are not counted.<br>The counter is not cleared on read. Furthermore, the register is a cyclic counter incrementing from 0xFFFF to 0x0000. |

### 8.3.2.6.6 VF Good Octets Transmitted Count LSB - VFGOTC\_LSB (0x00002020)

| Field      | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------|--------|-------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VFGOTC_LSB | 31:0   | 0x0   | RO   | <b>VF Good Octets Transmitted Count LSB</b><br>Number of good octets transmitted (32 LSB of a 36-bit counter) by the queues allocated to this VF.<br>This register includes bytes transmitted in a packet from the <i>Destination Address</i> field through the <i>CRC</i> field, inclusively. This register counts octets of the packets counted by the VFGPTC register. Octets are counted on the VF interface rather than on the network interface. For example, LinkSec octets are not counted.<br>The counter is not cleared on read. Furthermore, the register is a cyclic counter incrementing from 0xFFFF to 0x0000. |

### 8.3.2.6.7 VF Good Octets Transmitted Count MSB - VFGOTC\_MSB (0x00002024)

| Field      | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                  |
|------------|--------|-------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Furthermore, the register is a cyclic counter incrementing from 0xF to 0x0. |
| RESERVED   | 31:4   | 0x0   | RSV  | Reserved.                                                                                                                                                                                                                                                                                                                    |

## 8.3.3 BAR3 Registers Summary

Table 8-7. BAR3 Registers Summary

| Offset / Alias Offset             | Abbreviation   | Name                             | Page |
|-----------------------------------|----------------|----------------------------------|------|
| <b>MSI-X Table Registers - VF</b> |                |                                  |      |
| 0x00000000 + 0x10*n, n=0...2      | VFMSIXTADD[n]  | MSI-X Table Entry Lower Address  | 687  |
| 0x00000004 + 0x10*n, n=0...2      | VFMSIXTUADD[n] | MSI-X Table Entry Upper Address  | 687  |
| 0x00000008 + 0x10*n, n=0...2      | VFMSIXTMSG[n]  | MSI-X Table Entry Message        | 688  |
| 0x0000000C + 0x10*n, n=0...2      | VFMSIXVCTRL[n] | MSI-X Table Entry Vector Control | 688  |
| 0x00002000                        | VFMSIXPBA      | MSIXPBA Bit Description          | 688  |

## 8.3.4 Detailed Register Description - VF BAR3

### 8.3.4.1 MSI-X Table Registers - VF

#### 8.3.4.1.1 MSI-X Table Entry Lower Address - VFMSIXTADD[n] (0x00000000 + 0x10\*n, n=0...2)

| Field       | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                    |
|-------------|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MSIXTADD_10 | 1:0    | 00b   | RW   | <b>Message Address 1:0</b><br>For proper Dword alignment, software must always write zeros to these two bits. Otherwise, the result is undefined. The state of these bits after reset must be 0b. These bits are permitted to be read-only or read/write.                      |
| MSIXTADD    | 31:2   | 0x0   | RW   | <b>Message Address</b><br>System-specified message lower address.<br>For MSI-X messages, the contents of this field from an MSI-X table entry specifies the lower portion of the Dword-aligned address (AD[31:02]) for the memory write transaction. This field is read/write. |

#### 8.3.4.1.2 MSI-X Table Entry Upper Address - VFMSIXTUADD[n] (0x00000004 + 0x10\*n, n=0...2)

| Field     | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                        |
|-----------|--------|-------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MSIXTUADD | 31:0   | 0x0   | RW   | <b>Message Upper Address</b><br>System-specified message upper address bits. If this field is zero, Single Address Cycle (SAC) messages are used. If this field is non-zero, Dual Address Cycle (DAC) messages are used. This field is read/write. |

#### 8.3.4.1.3 MSI-X Table Entry Message - VFMSIXTMSG[n] (0x00000008 + 0x10\*n, n=0...2)

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                         |
|----------|--------|-------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MSIXTMSG | 31:0   | 0x0   | RW   | <b>Message Data</b><br>System-specified message data.<br>For MSI-X messages, the contents of this field from an MSI-X table entry specifies the data driven on AD[31:0] during the memory write transaction's data phase. This field is read/write. |

#### 8.3.4.1.4 MSI-X Table Entry Vector Control - VFMSIXVCTRL[n] (0x0000000C + 0x10\*n, n=0...2)

| Field     | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                      |
|-----------|--------|-------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MSIXVCTRL | 0      | 1b    | RW   | <b>Mask Bit</b><br>When this bit is set, the function is prohibited from sending a message using this MSI-X table entry. However, any other MSI-X table entries programmed with the same vector are still capable of sending an equivalent message unless they are also masked.<br>This bit's state after reset is 1b (entry is masked). This bit is read/write. |
| RESERVED  | 31:1   | 0x0   | RSV  | Reserved.<br>After reset, the state of these bits must be 0b. However, for potential future use, software must preserve the value of these reserved bits when modifying the value of other Vector Control bits. If software modifies the value of these reserved bits, the result is undefined.                                                                  |

#### 8.3.4.1.5 MSIXPBA Bit Description - VFMSIXPBA (0x00002000)

**Note:** If a page size larger than 8 K is programmed in the IOV structure, the address of the MSIX PBA table moves to be page aligned.

| Field        | Bit(s) | Init. | Type | Description                                                                                                                                                                                               |
|--------------|--------|-------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PENDING_BITS | 2:0    | 000b  | RO   | <b>Pending Bits</b><br>For each pending bit that is set, the function has a pending message for the associated MSI-X Table entry.<br>Pending bits that have no associated MSI-X table entry are reserved. |
| RESERVED     | 31:3   | 0x0   | RSV  | Reserved.                                                                                                                                                                                                 |

## 9.0 PCIe Programming Interface

---

### 9.1 Overview

The X550 is a multi-function device with the following functions:

- LAN 0
- LAN 1

Different parameters affect how LAN functions are exposed on PCIe.

Both functions contain the following regions of the PCI configuration space (some of them are enabled by NVM settings as detailed in the following sections):

- Mandatory PCI configuration registers - [Section 9.2.2](#)
- Legacy PCI capabilities - [Section 9.2.3](#)
  - Power management capabilities
  - MSI / MSI-X capabilities
  - Vital Product Data (VPD) capability
- PCIe extended capabilities - [Section 9.2.4](#)
  - Advanced Error Reporting (AER)
  - Serial ID
  - Alternate requester ID.
  - Single root IOV
  - Latency Tolerance Reporting
  - TPH Requester
  - Access Control Services
  - Secondary PCI Express

## 9.1.1 Register Attributes

Table 9-1 lists the register attributes used in this section.

**Table 9-1. Register Attribute Descriptions**

| Type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RO     | <b>Read-Only register</b><br>Register bits are read-only and cannot be altered by software.                                                                                                                                                                                                                                                                                                                                                               |
| RW     | <b>Read/Write register</b><br>Register bits are read-write and can be either set or reset.                                                                                                                                                                                                                                                                                                                                                                |
| RW1C   | <b>Read-only status — Write 1b to Clear status register</b><br>Writing a 0b to RW1C bits has no effect.                                                                                                                                                                                                                                                                                                                                                   |
| ROS    | <b>Read-Only register with Sticky bits</b><br>Register bits are read-only and cannot be altered by software. Bits are not cleared by reset and can only be reset with the PWRGOOD signal. Devices that consume AUX power are not allowed to reset sticky bits when AUX power consumption (either via AUX power or PME Enable) is enabled.                                                                                                                 |
| RWS    | <b>Read/Write register with Sticky bits</b><br>Register bits are read-write and can be either set or reset by software to the desired state. Bits are not cleared by reset and can only be reset with the PWRGOOD signal. Devices that consume AUX power are not allowed to reset sticky bits when AUX power consumption (either via AUX power or PME Enable) is enabled.                                                                                 |
| RW1CS  | <b>Read-only status — Write 1b to Clear status register</b><br>Register bits indicate status when read, a set bit, indicating a status event, can be cleared by writing a 1b to it. Writing a 0b to RW1C bits has no effect. Bits are not cleared by reset and can only be reset with the PWRGOOD signal. Devices that consume AUX power are not allowed to reset sticky bits when AUX power consumption (either via AUX power or PME Enable) is enabled. |
| HwInit | <b>Hardware Initialized</b><br>Register bits are initialized by firmware or hardware mechanisms such as pin strapping or serial NVM. Bits are read-only after initialization and can only be reset (for write-once by firmware) with the PWRGOOD signal.                                                                                                                                                                                                  |
| RsvdP  | <b>Reserved and Preserved</b><br>Reserved for future read/write implementations; software must preserve value read for writes to these bits.                                                                                                                                                                                                                                                                                                              |
| RsvdZ  | <b>Reserved and Zero</b><br>Reserved for future RW1C implementations; software must use 0b for writes to these bits.                                                                                                                                                                                                                                                                                                                                      |

## 9.2 PCIe Register Map

### 9.2.1 PCIe Configuration Space Summary

Table 9-2 lists the PCIe configuration registers while their detailed description is given in the sections that follow. PCI configuration fields in the summary table are presented by the following marking:

- Fields that have meaningful default values are indicated in parenthesis — **(value)**.
- Dotted fields indicates the same value for both LAN functions
- Light-blue fields indicate read-only fields (loaded from the NVM)
- Magenta fields indicate hard-coded values.
- Other fields contain RW attributes.

**Table 9-2. PCI Configuration Registers Map - LAN Functions**

| Section                 | Byte Offset | Byte 3                         | Byte 2                 | Byte 1                      | Byte 0                |
|-------------------------|-------------|--------------------------------|------------------------|-----------------------------|-----------------------|
| Mandatory PCI Register  | 0x0         | Device ID                      |                        | Vendor ID                   |                       |
|                         | 0x4         | Status Register                |                        | Command Register            |                       |
|                         | 0x8         | Class Code (0x020000/0x010000) |                        |                             | Revision ID           |
|                         | 0xC         | Reserved                       | Header Type (0x0/0x80) | Latency Timer               | Cache Line Size (0x0) |
|                         | 0x10        | Base Address Register 0        |                        |                             |                       |
|                         | 0x14        | Base Address Register 1        |                        |                             |                       |
|                         | 0x18        | Base Address Register 2        |                        |                             |                       |
|                         | 0x1C        | Base Address Register 3        |                        |                             |                       |
|                         | 0x20        | Base Address Register 4        |                        |                             |                       |
|                         | 0x24        | Base Address Register 5        |                        |                             |                       |

### 9.2.1.1 Sharing Among PCI Functions

The X550 supports multiple PCI functions. As each function exposes a PCIe configuration space, each register and each field is either shared among the functions or is replicated per each PCI function. In each section a table summarizes configuration sharing of the registers described in this section. Also, the description of each field describes special considerations regarding configuration sharing.

## 9.2.2 Mandatory PCI Configuration Registers

**Table 9-4. Configuration Sharing of PCI Configuration Space**

| Field                    | Sub-field                                       | Shared? | Replicated? | Comments                                                  |
|--------------------------|-------------------------------------------------|---------|-------------|-----------------------------------------------------------|
| Vendor ID                | Vendor ID                                       | x       |             |                                                           |
| Device ID                | Device ID                                       |         | x           |                                                           |
| Command Register         | I/O Access Enable                               |         | x           | Issue UR per PF if disabled.                              |
|                          | Memory Access Enable                            |         | x           | Issue UR per PF if disabled.                              |
|                          | Bus Master Enable                               |         | x           |                                                           |
|                          | Parity Error Response                           |         | x           | Enables certain error reporting per PF.                   |
|                          | SERR# Enable                                    |         | x           | Controls error reporting per PF.                          |
|                          | Interrupt Disable                               |         | x           | Selection of interrupt method per PF.                     |
| Status Register          | Interrupt Status                                |         | x           |                                                           |
|                          | Capabilities List                               | x       |             | Hard-wired to 1b.                                         |
|                          | Data Parity Reported / Master Data Parity Error |         | x           | Reports poisoned packets per PF.                          |
|                          | Signaled Target Abort                           |         | x           | Reports Completer Abort per PF.                           |
|                          | Received Target Abort                           |         | x           | Reports receiving a Completer Abort per PF.               |
|                          | Received Master Abort                           |         | x           | Reports receiving an UR per PF.                           |
|                          | Signaled System Error                           |         | x           | Reports Fatal / non-fatal message per PF.                 |
|                          | Detected Parity Error                           |         | x           | Reports receiving a poisoned TLP per PF.                  |
| Revision Register        |                                                 | x       |             |                                                           |
| Class Code Register      |                                                 |         | x           | Per function type.                                        |
| Cache Line Size Register |                                                 |         | x           | Does not affect device behavior.                          |
| Latency Timer            |                                                 | x       |             | Hard-wired to 00h in PCIe.                                |

| Interrupt Line Register |           |         | x           | Just store the register value.          |
| Interrupt Pin Register  |           |         | x           | Separate interrupt number (A-D) per PF. |
| Min. Grant              |           | x       |             |                                         |
| Max Latency             |           | x       |             |                                         |

### 9.2.2.1 Vendor ID Register (0x0; RO)

This is a read-only register that has the same value for all PCI functions. It identifies unique Intel products. The value of this field is loaded from the *PCI\_VENDORID* register loaded from NVM. The default value, if not loaded, is 0x8086.

### 9.2.2.2 Device ID Register (0x2; RO)

This is a read-only register that identifies individual X550 PCI functions. Both ports have the same default value equals to 0x1562, and can be auto-loaded from the NVM during initialization with different values for each port as well as the dummy function (See [Section 4.4](#) for dummy function relevance).

The device ID values available for different the X550 SKUs are:

- 0x1563: X550 LOM & NIC. This is the value used for LOM & Sage Pond NIC.
- 0x1564: X550 VF for Hyper-V. This is the value used for VFs under Hyper-V (windows 8). This value is never exposed as part of the hardware configuration space.
- 0x1565: X550 VF for non-Hyper-V. This is the value used for VFs under “other” virtual environments.

### 9.2.2.3 Command Register (0x4; RW)

Shaded bits are not used by this implementation and are hard-wired to 0b. Each function has its own Command register. Unless explicitly specified, functionality is the same in both functions.

| Bit(s) | Init. | Description                                                                                                                                                                        |

| 15     | 0b    | RW1C | <b>Detected Parity Error</b>                                                                                                                                                                                                                                                                                    |

1. The *Interrupt Status* field is a RO field that indicates that an interrupt message is pending internally to the device.

#### 9.2.2.5 Revision Register (0x8; RO)

The default revision ID of this device is 0x00 for X550 A0 and 0x01 for X550 B0. The value of the rev ID is a logic XOR between the default value and the value in the NVM PCIe Device Revision ID (PCI\_REVID). Note that LAN 0 and LAN 1 functions have the same revision ID.

#### 9.2.2.6 Class Code Register (0x9; RO)

The class code is a read-only value that identifies the device functionality according to the value of the *Storage Class* bit in the NVM *PCI\_CLASS* NVM register.

- Class Code = 0x020000 (Ethernet Adapter) if NVM->*Storage Class* = 0b
- Class Code = 0x010000 (SCSI Storage device) if NVM->*Storage Class* = 1b

In the dummy function the class code equals to 0xFF0000.

#### 9.2.2.7 Cache Line Size Register (0xC; RW)

This field is implemented by PCIe devices as a read/write field for legacy compatibility purposes but has no impact on any PCIe device functionality. The default value is zero.

### 9.2.2.8 Latency Timer (0xD; RO)

Not used. Hard-wired to 0b.

### 9.2.2.9 Header Type Register (0xE; RO)

This indicates if a device is single- or multi-function. If a single LAN function is the only active one, this field has a value of 0x00 to indicate a single function device. If other functions are enabled, this field has a value of 0x80 to indicate a multi-function device. [Table 9-5](#) lists the different options to set the header type field.

**Table 9-5. Header Type Settings**

| LAN 0 Enable | LAN 1 Enable | Cross-Mode Enable | Header Type Expected Value |
|--------------|--------------|-------------------|----------------------------|
| 0            | 0            | X                 | N/A (no function)          |
| 1            | 0            | 0                 | 0x00                       |
| 0            | 1            | 0                 | 0x80 (dummy exist)         |
| 1            | 1            | X                 | 0x80 (dual function)       |
| 1            | 0            | 1                 | 0x80 (dummy exist)         |
| 0            | 1            | 1                 | 0x00                       |

### 9.2.2.10 Subsystem Vendor ID Register (0x2C; RO)

This value can be loaded automatically from the NVM at power up or reset. A value of 0x8086 is the default for this field at power up if the NVM does not respond or is not programmed. All functions are initialized to the same value.

### 9.2.2.11 Subsystem ID Register (0x2E; RO)

This value can be loaded automatically from the NVM at power up with a default value of 0x0000.

| PCI Function  | Default Value | NVM Address |
|---------------|---------------|-------------|
| LAN Functions | 0x0000        | 0x0B        |

### 9.2.2.12 Cap\_Ptr Register (0x34; RO)

The *Capabilities Pointer* field (*Cap\_Ptr*) is an 8-bit field that provides an offset in the X550's PCI configuration space for the location of the first item in the capabilities linked list. The X550 sets this bit and implements a capabilities list to indicate that it supports PCI power management, MSIs, and PCIe extended capabilities. Its value is 0x40, which is the address of the first entry: PCI power management.

### 9.2.2.13 Interrupt Line Register (0x3C; RW)

Read/write register programmed by software to indicate which of the system interrupt request lines the X550's interrupt pin is bound to. Refer to the PCI definition for more details. Each PCI function has its own register.

### 9.2.2.14 Interrupt Pin Register (0x3D; RO)

Read-only register. LAN 0 / LAN 1 — A value of 0x1...0x4 indicates that this function implements a legacy interrupt on INTA#...INTD#, respectively. Loaded from the PCI\_CNF NVM word per function. For dummy function the returned value is 0x0 (Function uses no legacy interrupt Message).

**Note:** If only a single device/function of the X550 component is enabled, this value is ignored and the *Interrupt Pin* field of the enabled device reports INTA# usage.

### 9.2.2.15 Max\_Lat and Min\_Gnt (0x3E; RO)

Not used. Hard-wired to 0b.

For Dummy functions this register is RO - zero.

### 9.2.2.16 Memory and IO Base Address Registers (0x10...0x27; RW)

Base Address Registers (BARs) are used to map the X550 register space of the device functions. The X550 has a memory BAR, I/O BAR and MSI-X BAR described in Table 9-6. The BARs location and sizes are described in the Table 9-6 and Table 9-8. The fields within each BAR are then described in Table 9-8.

**Table 9-6. X550 Base Address Registers Description — LAN 0 / LAN 1**

| Mapping Windows | Mapping Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Memory BAR      | The internal registers memories and external Flash device are accessed as direct memory mapped offsets from the BAR. Software can access a Dword or 64 bits.<br>The Flash space in this BAR is enabled by the <i>FL_BAR_SIZE</i> and <i>CSRSIZE</i> fields in the <i>PCI_LBARCTRL</i> register. Address 0 in the Flash device is mapped to address 256 K in the memory BAR. When the usable Flash size + CSR space are smaller than the memory BAR, accessing addresses above the top of the Flash wraps back to the beginning of the Flash. |
| I/O BAR         | All internal registers and memories can be accessed using I/O operations. There are two 4-byte registers in the I/O mapping window: Addr Reg and Data Reg accessible as Dword entities. The I/O BAR is supported depending on the <i>IO_Sup</i> bit in the NVM at word <i>PCIe Control 3 – Offset 0x07</i> .                                                                                                                                                                                                                                 |
| MSI-X BAR       | The MSI-X vectors and Pending Bit Array (PBA) structures are accessed as direct memory mapped offsets from the MSI-X BAR. Software can access Dword entities.                                                                                                                                                                                                                                                                                                                                                                                |

**Table 9-7. X550 Base Address Setting in 64-bit BARs Mode**

| BAR | Addr | 31                                       | 5 | 4 | 3   | 2 | 1 | 0 |
|-----|------|------------------------------------------|---|---|-----|---|---|---|
| 0   | 0x10 | Memory CSR + FLASH BAR Low see Table 9-8 |   |   | 0/1 | 1 | 0 | 0 |
| 1   | 0x14 | Memory CSR + FLASH BAR High (RW)         |   |   |     |   |   |   |
| 2   | 0x18 | IO BAR (RW — 31:5)                       |   | 0 | 0   | 0 | 0 | 1 |
| 3   | 0x1C | Reserved (RO — 0)                        |   |   |     |   |   |   |
| 4   | 0x20 | MSI-X BAR Low (RW — 31:14; RO 0b — 13:4) |   |   | 0/1 | 1 | 0 | 0 |
| 5   | 0x24 | MSI-X BAR High (RW)                      |   |   |     |   |   |   |

**Table 9-8. Base Address Registers Fields**

| Field                                                  | Bit(s) | Type | Description                                                                                                                                                                                                                                                                     |
|--------------------------------------------------------|--------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| 111b        | 1       | 16 MB                         | 8 MB                   | 8 MB               |

### 9.2.2.17 Expansion ROM Base Address Register (0x30; RW)

This register is used to define the address and size information for boot-time access to the Expansion ROM Module in the Flash memory. It is enabled by the PCI\_LBARCTRL.EXROM\_DIS register field. This register returns a zero value for functions without an expansion ROM window and for dummy functions.

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                            |
|----------|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| En       | 0      | 0b    | RW   | <b>Enable</b><br>0b = Disables expansion ROM access.<br>1b = Enables expansion ROM access.                                                                                                                                                             |
| Reserved | 10:1   | 0x0   | R    | Reserved.<br>Always read as 0x0. Writes are ignored.                                                                                                                                                                                                   |
| Address  | 31:11  | 0x0   | RW   | <b>Address</b><br>Read-write bits are hard-wired to 0b and dependent on the memory mapping window size. The LAN Expansion ROM spaces can be either 64 KB or up to 8MB in powers of 2. Mapping window size is set by PCI_LBARCTRL.EXROM_BAR_SIZE field. |

## 9.2.3 PCI Capabilities

The first entry of the PCI capabilities link list is pointed to by the Cap\_Ptr register. Table 9-10 lists the capabilities supported by the X550.

**Table 9-10. PCI Capabilities List for LAN Functions**

| Address   | Item                 | Next Pointer             |
|-----------|----------------------|--------------------------|
| 0x40:4F   | PCI Power Management | 0x50 / 0xA0 <sup>1</sup> |
| 0x50:6F   | MSI                  | 0x70                     |
| 0x70:8F   | MSI-X                | 0xA0                     |
| 0xA0:DF   | PCIe Capabilities    | 0xE0 / 0x00              |
| 0xE0:0xEF | VPD Capability       | 0x00                     |

1. In the dummy function, the power management capability points to the PCIe capabilities.

**Table 9-11. PCI Capabilities for Dummy Function**

| Address | Item                 | Next Pointer |
|---------|----------------------|--------------|
| 0x40:47 | PCI Power Management | 0x50         |
| 0xA0:DB | PCIe Capabilities    | 0x00         |

### 9.2.3.1 PCI Power Management Capability

All fields are reset at full power up. All fields except *PME\_En* and *PME\_Status* are reset after exiting from the D3cold state. If AUX power is not supplied, the *PME\_En* and *PME\_Status* fields also reset after exiting from the D3cold state. Refer to the detailed description for registers loaded from the NVM at initialization.

**Table 9-12. PCI Power Management Capability Structure**

| Byte Offset | Byte 3                        | Byte 2                    | Byte 1                            | Byte 0               |
|-------------|-------------------------------|---------------------------|-----------------------------------|----------------------|
| 0x40        | Power Management Capabilities |                           | Next Pointer (0x50 / 0xA0)        | Capability ID (0x01) |
| 0x44        | Data                          | Bridge Support Extensions | Power Management Control & Status |                      |

Table 9-13 summarizes sharing of the Power Management Capability registers among the different PCI functions.

**Table 9-13. Sharing the Power Management Capability Registers**

| Field                             | Sub-field     | Shared? | Replicated? | Comments          |
|-----------------------------------|---------------|---------|-------------|-------------------|
| Capability ID                     |               | x       |             |                   |
| Next Pointer                      |               |         | x           |                   |
| Power Management Capabilities     | PME_Support   | x       |             |                   |
|                                   | D2_Support    | x       |             |                   |
|                                   | D1_Support    | x       |             |                   |
|                                   | AUX Current   | x       |             |                   |
|                                   | DSI           | x       |             |                   |
|                                   | PME Clock     | x       |             | Hard-wired to 0b. |
|                                   | Version       | x       |             |                   |
| Power Management Control / Status | PME_Status    |         | x           |                   |
|                                   | Data_Scale    | x       |             |                   |
|                                   | Data_Select   |         | x           |                   |
|                                   | PME_En        |         | x           |                   |
|                                   | No_Soft_Reset | x       |             |                   |

| Data Register                     |               |         | x           |                   |

#### 9.2.3.1.1 Capability ID Register (0x40; RO)

This field equals 0x01 indicating the linked list item as being the PCI Power Management registers.

#### 9.2.3.1.2 Next Pointer Register (0x41; RO)

This field provides an offset to the next capability item in the capability list. This field equals for both LAN ports to 0x50 pointing to the MSI capability. In dummy function, it equals to 0xA0 pointing to the PCIe Capabilities.

### 9.2.3.1.3 Power Management Capabilities — PMC Register (0x42; RO)

This register describes the device functionality during the power management states as listed in the following table. Note that each device function has its own register.

| Bit(s) | Init.  | Type | Description                                                                                                                                                                                                                                                                                              |
|--------|--------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2:0    | 011b   | RO   | <b>Version</b><br>The X550 complies with the PCI PM specification revision 1.2.                                                                                                                                                                                                                          |

### 9.2.3.1.4 Power Management Control/Status Register — PMCSR (0x44; RW)

This register is used to control and monitor power management events in the device. Note that each device function has its own PMCSR.

| Bit(s) | Init.             | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------|-------------------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1:0    | 00b               | RW   | <b>PowerState</b><br>This field is used to set and report the power state of a function as follows:<br>00b = D0<br>01b = D1 (cycle ignored if written with this value)<br>10b = D2 (cycle ignored if written with this value)<br>11b = D3                                                                                                                                                                                      |
| 2      | 0b                | RO   | Reserved for PCIe.                                                                                                                                                                                                                                                                                                                                                                                                             |
| 3      | 1b                | RO   | <b>No_Soft_Reset</b><br>This bit is always set to 1b to indicate that the X550 does not perform an internal reset upon transition from D3hot to D0 via software control of the <i>PowerState</i> bits. Configuration context is kept as part of the transition from the D3hot to the D0 state, thus a full re-initialization sequence of the configuration space is not needed to return the X550 to the D0 Initialized state. |
| 7:4    | 0x0               | RO   | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 8      | 0b<br>at power up | RWS  | <b>PME_En</b><br>If power management is enabled in the NVM. | 14:13  | 01b            | RO    | <b>Data_Scale</b><br>This field indicates the scaling factor that is used when interpreting the value of the Data register.<br>This field equals 01b (indicating 0.1 watt/units) if the <i>Data_Select</i> field is set to 0, 3, 4, 7, (or 8 for function 0 in multi-function device). Otherwise, it equals 00b. |
| 15     | 0b at power up | RW1CS | <b>PME_Status</b><br>This bit is set to 1b when the function detects a wake-up event independent of the state of the <i>PME_En</i> bit. Writing a 1b clears this bit.                                                                                                                                            |

### 9.2.3.1.5 PMCSR\_BSE Bridge Support Extensions Register (0x46; RO)

This register is not implemented in the X550; values set to 0x00.

### 9.2.3.1.6 Data Register (0x47; RO)

This optional register is used to report power consumption and heat dissipation. The reported register is controlled by the *Data\_Select* field in the PMCSR; the power scale is reported in the *Data\_Scale* field in the PMCSR. The data for this field is loaded from the NVM via the PCI\_PWRDATA register if power management is enabled in the NVM or with a default value of 0x00. The values for the X550's functions are as follows (the relevant column is selected based on the value of the *Data\_Select* field):

| Function           | D0 (Consume/ Dissipate) | D3 (Consume/ Dissipate) | Common                                                                                                 | Data_Scale |
|--------------------|-------------------------|-------------------------|--------------------------------------------------------------------------------------------------------|------------|
| <b>Data_Select</b> | (0x0/0x4)               | (0x3/0x7)               | (0x8)                                                                                                  |            |
| 0                  | PCI_PWRDATA.D0_POWER    | PCI_PWRDATA.D3_POWER    | Function zero of a Multi-function device:<br>PCI_PWRDATA.COMM_POWER<br>Single-function device:<br>0x00 | 01b        |
| 1                  | PCI_PWRDATA.D0_POWER    | PCI_PWRDATA.D3_POWER    | 0x00                                                                                                   | 01b        |

**Note:** For other *Data\_Select* values the Data register output is reserved (0b).

### 9.2.3.2 MSI Capability

**Note:** This capability is not available for dummy functions.

This structure is required for PCIe devices.

**Table 9-14. MSI Capability Structure**

| Byte Offset | Byte 3                   | Byte 2 | Byte 1              | Byte 0               |
|-------------|--------------------------|--------|---------------------|----------------------|
| 0x50        | Message Control (0x0080) |        | Next Pointer (0x70) | Capability ID (0x05) |
| 0x54        | Message Address          |        |                     |                      |
| 0x58        | Message Upper Address    |        |                     |                      |
| 0x5C        | Reserved                 |        | Message Data        |                      |
| 0x60        | Mask Bits                |        |                     |                      |
| 0x64        | Pending Bits             |        |                     |                      |

Table 9-15 summarizes configuration sharing of the MSI Capability registers among the different PCI functions.

**Table 9-15. Configuration Sharing of the MSI Capability**

| Field                | Sub-field                 | Shared? | Replicated? | Comments |
|----------------------|---------------------------|---------|-------------|----------|
| Capability ID        |                           | x       |             |          |
| Next Pointer         |                           |         | x           |          |
| Message Control      | MSI Enable                |         | x           |          |
|                      | Multiple Messages Capable | x       |             |          |
|                      | Multiple Message Enable   |         | x           |          |
|                      | 64-bit Capable            | x       |             |          |
|                      | MSI per-vector masking    | x       |             |          |
| Message Address Low  |                           |         | x           |          |
| Message Address High |                           |         | x           |          |
| Message Data         |                           |         | x           |          |
| Mask Bits            |                           |         | x           |          |
| Pending Bits         |                           |         | x           |          |

### 9.2.3.2.1 Capability ID Register (0x50; RO)

This field equals 0x05 indicating that the linked list item as being the MSI registers.

### 9.2.3.2.2 Next Pointer Register (0x51; RO)

This field provides an offset to the next capability item in the capability list. Its value of 0x70 and points to MSI-X capability.

### 9.2.3.2.3 Message Control Register (0x52; RW)

**Note:** There is a dedicated register (per PCI function) to separately enable its MSI.

| Bit(s) | Init.           | Type | Description                                                                                                                                                                          |
|--------|-----------------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0      | 0b              | RW   | <b>MSI Enable</b><br>1b = Message Signaled Interrupts — The X550 generates an MSI for interrupt assertion instead of INTx signaling.                                                 |
| 3:1    | 000b            | RO   | <b>Multiple Messages Capable</b><br>The X550 indicates a single requested message per function.                                                                                      |
| 6:4    | 000b            | RW   | <b>Multiple Message Enable</b><br>Since the X550 requests a single vector in the <i>Multiple Message Capable</i> field, software is expected to write 000b to this field.            |
| 7      | 1b              | RO   | <b>64-bit Capable</b><br>A value of 1b indicates that the X550 is capable of generating 64-bit message addresses.                                                                    |
| 8      | 1b <sup>1</sup> | RO   | <b>MSI per-vector masking</b><br>A value of 0b indicates that the X550 is not capable of per-vector masking. A value of 1b indicates that the X550 is capable of per-vector masking. |
| 15:9   | 0x0             | RO   | Reserved. Reads as 0x0.                                                                                                                                                              |

1. The value is loaded from the MSI Mask bit in the NVM.

#### 9.2.3.2.4 Message Address Low Register (0x54; RW)

Written by the system to indicate the lower 32 bits of the address to use for the MSI memory write transaction. The lower two bits always return 0b regardless of the write operation.

#### 9.2.3.2.5 Message Address High Register (0x58; RW)

Written by the system to indicate the upper 32 bits of the address to use for the MSI memory write transaction.

#### 9.2.3.2.6 Message Data Register (0x5C; RW)

Written by the system to indicate the lower 16 bits of the data written in the MSI memory write Dword transaction. The upper 16 bits of the transaction are written as 0b.

#### 9.2.3.2.7 Mask Bits Register (0x60; RW)

The Mask Bits and Pending Bits registers enable software to disable or defer message sending on a per-vector basis. As the X550 supports only one message, only bit 0 of these registers are implemented.

| Bit(s) | Init. | Type | Description                                                                           |
|--------|-------|------|---------------------------------------------------------------------------------------|
| 0      | 0b    | RW   | <b>MSI Vector 0 Mask</b><br>If set, the X550 is prohibited from sending MSI messages. |
| 31:1   | 0x0   | RO   | Reserved.                                                                             |

#### 9.2.3.2.8 Pending Bits Register (0x64; RW)

| Bit(s) | Init. | Type | Description                                                       |
|--------|-------|------|-------------------------------------------------------------------|
| 0      | 0b    | RO   | <b>MSI Message</b><br>If set, the X550 has a pending MSI message. |
| 31:1   | 0x0   | RO   | Reserved.                                                         |

### 9.2.3.3 MSI-X Capability

**Note:** This capability is not available for dummy functions.

More than one MSI-X capability structure per function is prohibited while a function is permitted to have both an MSI and an MSI-X capability structure.

In contrast to the MSI capability structure, which directly contains all of the control/status information for the function's vectors, the MSI-X capability structure instead points to an MSI-X table structure and an MSI-X Pending Bit Array (PBA) structure, each residing in memory space.

Each structure is mapped by a BAR belonging to the function that begins at 0x10 in the configuration space. A BAR Indicator Register (BIR) indicates which BAR and a Qword-aligned offset indicates where the structure begins relative to the base address associated with the BAR. The BAR is 64-bit, but must map to the memory space. A function is permitted to map both structures with the same BAR or map each structure with a different BAR.

The MSI-X table structure (Section 9.2.3.4) typically contains multiple entries, each consisting of several fields: *Message Address*, *Message Upper Address*, *Message Data*, and *Vector Control*. Each entry is capable of specifying a unique vector.

The PBA structure [MSI-X Table Offset Register (0x74; RW)] contains the function's pending bits, one per table entry, organized as a packed array of bits within Qwords. The last Qword is not necessarily fully populated.

To request service using a given MSI-X table entry, a function performs a Dword memory write transaction using:

- The contents of the *Message Data* field entry for data.
- The contents of the *Message Upper Address* field for the upper 32 bits of the address.
- The contents of the *Message Address* field entry for the lower 32 bits of the address.

A memory read transaction from the address targeted by the MSI-X message produces undefined results.

The MSI-X table and MSI-X PBA are permitted to co-reside within a naturally aligned 4 KB address range, though they must not overlap with each other.

MSI-X table entries and *Pending* bits are each numbered 0 through N-1, where N-1 is indicated by the *Table Size* field in the MSI-X Message Control register. For a given arbitrary MSI-X table entry K, its starting address can be calculated with the formula:

Entry starting address = Table base + K\*16

For the associated *Pending* bit K, its address for Qword access and bit number within that Qword can be calculated with the formulas:

Qword address = PBA base + (K div 64)\*8

Qword bit# = K mod 64

Software that chooses to read *Pending* bit K with Dword accesses can use these formulas:

Dword address = PBA base + (K div 32)\*4

Dword bit# = K mod 32

**Table 9-16. MSI-X Capability Structure**

| Byte Offset | Byte 3                    | Byte 2 | Byte 1              | Byte 0               |
|-------------|---------------------------|--------|---------------------|----------------------|
| 0x70        | Message Control (0x00090) |        | Next Pointer (0xA0) | Capability ID (0x11) |
| 0x74        | Table Offset              |        |                     |                      |
| 0x78        | PBA Offset                |        |                     |                      |

Table 9-17 summarizes configuration sharing of the MSI-X Capability registers among the different PCI functions.

**Table 9-17. Configuration Sharing of the MSI-X Capability**

| Field           | Sub-field  | Shared? | Replicated? | Comments |
|-----------------|------------|---------|-------------|----------|
| Capability ID   |            | x       |             |          |
| Next Pointer    |            |         | x           |          |
| Message Control | Table Size | x       |             |          |
| Function Mask   |            |         | x           |          |

### 9.2.3.3.1 Capability ID Register (0x70; RO)

This field equals 0x11 indicating that the linked list item as being the MSI-X registers.

### 9.2.3.3.2 Next Pointer Register (0x71; RO)

This field provides an offset to the next capability item in the capability list. Its value of 0xA0 points to PCIe capability.

### 9.2.3.3.3 Message Control Register (0x72; RW)

**Note:** There is a dedicated register (per PCI function).

| Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------|-------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10:0   | 0x3F  | RO   | <b>Table Size</b><br>System software reads this field to determine the MSI-X Table Size N, which is encoded as N-1. The X550 supports up to 64 different interrupt vectors per function.<br>This field is loaded from the PCI_CNF2.MSI_X_PF_N register field.                                                                                                                                                                                      |
| 13:11  | 000b  | RO   | Reserved. Always returns 000b on a read. A write operation has no effect.                                                                                                                                                                                                                                                                                                                                                                          |
| 14     | 0b    | RW   | <b>Function Mask</b><br>0b = Each vector's <i>Mask</i> bit determines whether the vector is masked or not.<br>1b = All of the vectors associated with the function are masked, regardless of their per-vector <i>Mask</i> bit states.<br>Setting or clearing the MSI-X <i>Function Mask</i> bit has no effect on the state of the per-vector <i>Mask</i> bits.                                                                                     |
| 15     | 0b    | RW   | <b>MSI-X Enable</b><br>0b = The function is prohibited from using MSI-X to request service.<br>1b = If 1b and the <i>MSI Enable</i> bit in the MSI Message Control register is 0b, the function is permitted to use MSI-X to request service and is prohibited from using its INTx# pin.<br>System configuration software sets this bit to enable MSI-X. A device driver is prohibited from writing this bit to mask a function's service request. |

#### 9.2.3.3.4 MSI-X Table Offset Register (0x74; RW)

| Bit(s) | Init.   | Type | Description                                                                                                                                                                                                                                                                                |
|--------|---------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2:0    | 0x3/0x4 | RO   | <b>Table BIR</b><br>Indicates which one of a function's BARs, beginning at 0x10 in the configuration space, is used to map the function's MSI-X table into the memory space. while BIR values: 0...5 correspond to BARs 0x10...0x 24, respectively.                                        |
| 31:3   | 0x0     | RO   | <b>Table Offset</b><br>Used as an offset from the address contained in one of the function's BARs to point to the base of the MSI-X table. The lower three <i>Table BIR</i> bits are masked off (set to 0b) by software to form a 32-bit Qword-aligned offset.<br>This field is read only. |

#### 9.2.3.3.5 MSI-X Pending Bit Array — PBA Offset (0x78; RW)

| Bit(s) | Init.  | Type | Description                                                                                                                                                                                                                                                                         |
|--------|--------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2:0    | 0x4    | RO   | <b>PBA BIR</b><br>Indicates which one of a function's BARs, beginning at 0x10 in the configuration space, is used to map the function's MSI-X PBA into the memory space. while BIR values: 0...5 correspond to BARs 0x10...0x 24, respectively.                                     |
| 31:3   | 0x0400 | RO   | <b>PBA Offset</b><br>Used as an offset from the address contained in one of the functions BARs to point to the base of the MSI-X PBA. The lower three <i>PBA BIR</i> bits are masked off (set to 0b) by software to form a 32-bit Qword-aligned offset.<br>This field is read only. |

#### 9.2.3.4 MSI-X Table Structure

| Dword3 — MSIXTVCTRL | Dword2 — MSIXMSG | Dword1 — MSIXTUADD | Dword0 — MSIXTADD | Entry Number | BAR 3 — Offset |
|---------------------|------------------|--------------------|-------------------|--------------|----------------|
| Vector Control      | Msg Data         | Msg Upper Address  | Msg Lower Address | 0            | Base (0x0000)  |
| Vector Control      | Msg Data         | Msg Upper Address  | Msg Lower Address | 1            | Base + 1*16    |
| Vector Control      | Msg Data         | Msg Upper Address  | Msg Lower Address | 2            | Base + 2*16    |
| ...                 | ...              | ...                | ...               | ...          |                |
| Vector Control      | Msg Data         | Msg Upper Address  | Msg Lower Address | 63           | Base + 63*16   |
| Vector Control      | Msg Data         | Msg Upper Address  | Msg Lower Address | 64           | Base + 64*16   |
| ...                 | ...              | ...                | ...               | ...          |                |
| Vector Control      | Msg Data         | Msg Upper Address  | Msg Lower Address | 255          | Base + 255*16  |

**Note:** All MSI-X vectors > MSI-X 63, are usable only by the Virtual Functions (VFs) in IOV mode. These vectors are not exposed to the operating system by the *Table Size* field in the *MSI-X Message Control* word.

See [Section 8.2.2.7](#) for details of the MSI-X registers in BAR 3 of the PF.

### 9.2.3.5 VPD Registers

**Note:** This capability is not available for dummy functions.

The X550 supports access to a VPD structure stored in the NVM using the following set of registers.

Initial values of the configuration registers are marked in parenthesis.

**Note:** The VPD structure is available through both ports functions. As the interface is common to the two functions, accessing the VPD structure of one function while an access to the NVM is in process on the other function can yield to unexpected results.

**Table 9-18. VPD Capability Structure**

| Byte Offset | Byte 3      | Byte 2 | Byte 1              | Byte 0               |
|-------------|-------------|--------|---------------------|----------------------|
| 0xE0        | VPD Address |        | Next Pointer (0x00) | Capability ID (0x03) |
| 0xE4        | VPD Data    |        |                     |                      |

Table 9-19 summarizes configuration sharing of the VPD Capability registers among the different PCI functions.

**Table 9-19. Configuration Sharing of the VPD Capability**

| Field         | Shared? | Replicated? | Comments |
|---------------|---------|-------------|----------|
| Capability ID | X       |             |          |
| Next Pointer  | X       |             |          |
| VPD Address/F | X       |             |          |
| VPD Data      | X       |             |          |

#### 9.2.3.5.1 Capability ID Register (0xE0; RO)

This field equals 0x3 indicating the linked list item as being the VPD registers.

#### 9.2.3.5.2 Next Pointer Register (0xE1; RO)

Offset to the next capability item in the capability list. A 0x00 value indicates that it is the last item in the capability-linked list.

#### 9.2.3.5.3 VPD Address Register (0xE2; RW)

Word-aligned byte address of the VPD area in the NVM to be accessed. The register is read/write, and the initial value at power-up is indeterminate.

| Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------|-------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14:0   | X     | RW   | <b>Address</b><br>Dword-aligned byte address of the VPD area in the NVM to be accessed. The register is read/write, and the initial value at power-up is indeterminate. The two LSBs are RO as zero.                                                                                                                                                                                                          |
| 15     | 0b    | RW   | <b>F</b><br>A flag used to indicate when the transfer of data between the VPD Data register and the storage component completes. The Flag register is written when the VPD Address register is written.<br>0b = Read — Set by hardware when data is valid.<br>1b = Write — Cleared by hardware when data is written to the NVM.<br>The VPD address and data should not be modified before the action is done. |

### 9.2.3.5.4 VPD Data Register (0xE4; RW)

VPD read/write data.

| Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------|-------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0   | X     | RW   | <b>VPD Data</b><br>VPD data can be read or written through this register. The LS byte of this register (at offset 4 in this capability structure) corresponds to the byte of VPD at the address specified by the VPD Address register. The data read from or written to this register uses the normal PCI byte transfer capabilities. Four bytes are always transferred between this register and the VPD storage component. Reading or writing data outside of the VPD space in the storage component is not allowed.<br>In a write access, the data should be set before the address and the flag is set. |

### 9.2.3.6 PCIe Capability

The X550 implements the PCIe capability structure linked to the legacy PCI capability list for endpoint devices as follows:

**Table 9-20. PCIe Capability Structure**

| Byte Offset | Byte 3                                   | Byte 2 | Byte 1                   | Byte 0               |
|-------------|------------------------------------------|--------|--------------------------|----------------------|
| 0xA0        | PCI Express Capability Register (0x0002) |        | Next Pointer (0xE0/0x00) | Capability ID (0x10) |
| 0xA4        | Device Capability                        |        |                          |                      |
| 0xA8        | Device Status                            |        | Device Control           |                      |
| 0xAC        | Link Capability                          |        |                          |                      |
| 0xB0        | Link Status                              |        | Link Control             |                      |
| 0xB4        | Reserved                                 |        |                          |                      |
| 0xB8        | Reserved                                 |        | Reserved                 |                      |
| 0xBC        | Reserved                                 |        |                          |                      |
| 0xC0        | Reserved                                 |        | Reserved                 |                      |
| 0xC4        | Device Capability 2                      |        |                          |                      |

### 9.2.3.6.1 Capability ID Register (0xA0; RO)

This field equals 0x10 indicating that the linked list item as being the PCIe Capabilities registers.

### 9.2.3.6.2 Next Pointer Register (0xA1; RO)

Offset to the next capability item in the capability list. Its value of 0xE0 points to the VPD structure. If VPD is disabled or for a dummy function, a value of 0x00 value indicates that it is the last item in the capability-linked list.

### 9.2.3.6.3 PCIe Capabilities Register (0xA2; RO)

The PCIe Capabilities register identifies PCIe device type and associated capabilities. This is a read-only register identical to all functions.

| Bit(s) | Init. | Type | Description                                                                                                                                                                |
|--------|-------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3:0    | 0x2   | RO   | <b>Capability Version</b><br>Indicates the PCIe capability structure version. The X550 supports PCIe version 2 (also loaded from the PCI_CAPSUP.PCI_E_VER bit in the NVM). |
| 7:4    | 0x0   | RO   | <b>Device/Port Type</b><br>Indicates the type of PCIe functions. All functions are native PCI functions with a value of 0x0.                                               |
| 8      | 0b    | RO   | <b>Slot Implemented</b><br>The X550 does not implement slot options. Therefore, this field is hard-wired to 0b.                                                            |
| 13:9   | 0x0   | RO   | <b>Interrupt Message Number</b><br>The X550 does not implement multiple MSI per function. As a result, this field is hard-wired to 0x0.                                    |
| 15:14  | 00b   | RO   | Reserved.                                                                                                                                                                  |

### 9.2.3.6.4 Device Capabilities Register (0xA4; RO)

This register identifies the PCIe device specific capabilities. It is a read-only register with the same value for the two LAN functions and for all other functions.

| Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                            |
|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2:0    | 010b  | RO   | <b>Max Payload Size Supported</b><br>This field indicates the maximum payload that The X550 can support for TLPs. It is loaded from the NVM with a default value of 512 bytes.                                                                                                                         |
| 4:3    | 00b   | RO   | <b>Phantom Function Supported</b><br>Not supported by the X550.                                                                                                                                                                                                                                        |
| 5      | 0b    | RO   | <b>Extended Tag Field Supported</b><br>Maximum supported size of the <i>Tag</i> field. The X550 supports a 5-bit <i>Tag</i> field for all functions.                                                                                                                                                   |
| 8:6    | 011b  | RO   | <b>Endpoint L0s Acceptable Latency</b><br>This field indicates the acceptable latency that the X550 can withstand due to the transition from L0s state to the L0 state. All functions share the same value loaded from the NVM PCIe Init Configuration 1 bits [8:6].<br>A value of 011b equals 512 ns. |
| 11:9   | 110b  | RO   | <b>Endpoint L1 Acceptable Latency</b><br>This field indicates the acceptable latency that the X550 can withstand due to the transition from L1 state to the L0 state.<br>A value of 110b equals 32 $\mu$ s to 64 $\mu$ s.<br>All functions share the same value loaded from the NVM.                   |
| 12     | 0b    | RO   | <b>Attention Button Present</b><br>Hard-wired in the X550 to 0b for all functions.                                                                                                                                                                                                                     |
| 13     | 0b    | RO   | <b>Attention Indicator Present</b><br>Hard-wired in the X550 to 0b for all functions.                                                                                                                                                                                                                  |
| 14     | 0b    | RO   | <b>Power Indicator Present</b><br>Hard-wired in the X550 to 0b for all functions.                                                                                                                                                                                                                      |

### 9.2.3.6.8 Link Control Register (0xB0; RO)

This register controls PCIe link specific parameters. There is a dedicated register per each function.

| Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

The following registers are supported only if the capability version is two and above.

### 9.2.3.6.10 Device Capability 2 Register (0xC4; RO)

This register identifies the PCIe device-specific capabilities. It is a read-only register with the same value for both LAN functions.

| Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

### 9.2.3.6.11 Device Control 2 Register (0xC8; RW)

This register controls the PCIe specific parameters. Note that there is a dedicated register per each function.

| Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## 9.2.4 PCIe Extended Configuration Space

PCIe configuration space is located in a flat memory-mapped address space. PCIe extends the configuration space beyond the 256 bytes available for PCI to 4096 bytes. The X550 decodes an additional four bits (bits 27:24) to provide the additional configuration space as shown. PCIe reserves the remaining four bits (bits 31:28) for future expansion of the configuration space beyond 4096 bytes.

The configuration address for a PCIe device is computed using a PCI-compatible bus, device, and function numbers as follows:

|           |           |           |           |           |           |           |           |                           |          |          |          |
|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|---------------------------|----------|----------|----------|
| <b>31</b> | <b>28</b> | <b>27</b> | <b>20</b> | <b>19</b> | <b>15</b> | <b>14</b> | <b>12</b> | <b>11</b>                 | <b>2</b> | <b>1</b> | <b>0</b> |
| 0000b     |           | Bus #     |           | Device #  |           | Fun #     |           | Register Address (offset) |          |          | 00b      |

PCIe extended configuration space is allocated using a linked list of optional or required PCIe extended capabilities following a format resembling PCI capability structures. The first PCIe extended capability is located at offset 0x100 in the device configuration space. The first Dword of the capability structure identifies the capability/version and points to the next capability.

The X550 supports the following PCIe extended capabilities:

**Table 9-22. Extended Capabilities List**

| Capability                                 | Offset | Next Header                           | Page |
|--------------------------------------------|--------|---------------------------------------|------|
| Advanced Error Reporting                   | 0x100  | Any of the below / 0x000              | 724  |
| Serial Number                              | 0x140  | Any of the below / 0x000 <sup>1</sup> | 729  |
| Alternative RID Interpretation (ARI)       | 0x150  | Any of the below / 0x000 <sup>1</sup> | 731  |
| IOV Support <sup>2</sup>                   | 0x160  | Any of the below / 0x000              | 732  |
| TPH Requester                              | 0x1A0  | Any of the below / 0x000              | 738  |
| Access Control Services (ACS) <sup>3</sup> | 0x1B0  | Any of the below / 0x000              | 740  |
| Latency Tolerance Reporting (LTR)          | 0x1C0  | Any of the below / 0x000              | 741  |
| Secondary PCI Express                      | 0x1D0  | 0x000                                 | 743  |

1. Depends on NVM settings enabling the ARI/IOV structures.

2. In a dummy function, the IOV and TPH structures are not exposed.

3. When in Single function mode (function 1 is disabled), the ACS capability is not exposed.

### 9.2.4.1 Advanced Error Reporting Capability (AER)

The PCIe advanced error reporting capability is an optional extended capability to support advanced error reporting. The tables that follow list the PCIe advanced error reporting extended capability structure for PCIe devices.

**Table 9-23. AER Capability Structure**

| Byte Offset | Byte 3                       | Byte 2 | Byte 1        | Byte 0                     |
|-------------|------------------------------|--------|---------------|----------------------------|
| 0x100       | Next Capability offset       |        | Version (0x1) | AER Capability ID (0x0001) |
| 0x104       | Uncorrectable Error Status   |        |               |                            |
| 0x108       | Uncorrectable Error Mask     |        |               |                            |
| 0x10C       | Uncorrectable Error Severity |        |               |                            |

**Table 9-23. AER Capability Structure (Continued)**

| Byte Offset    | Byte 3                                           | Byte 2 | Byte 1 | Byte 0 |
|----------------|--------------------------------------------------|--------|--------|--------|
| 0x110          | Correctable Error Status                         |        |        |        |
| 0x114          | Correctable Error Mask                           |        |        |        |
| 0x118          | Advanced Error Capabilities and Control Register |        |        |        |
| 0x11C... 0x128 | Header Log                                       |        |        |        |

Table 9-24 summarizes configuration sharing of the AER Capability registers among the different PCI functions.

**Table 9-24. Configuration Sharing of the AER Capability**

| Field                                   | Sub-field               | Shared? | Replicated? | Comments                              |
|-----------------------------------------|-------------------------|---------|-------------|---------------------------------------|
| Enhanced Capability Header Register     | Extended Capability ID  | x       |             |                                       |
|                                         | Capability Version      | x       |             |                                       |
|                                         | Next Capability Offset  |         | x           |                                       |

### 9.2.4.1.2 Uncorrectable Error Status Register (0x104; RW1CS)

The Uncorrectable Error Status register reports error status of individual uncorrectable error sources on a PCIe device. An individual error status bit that is set to 1b indicates that a particular error occurred; software can clear an error status by writing a 1b to the respective bit. Register is cleared by LAN\_PWR\_GOOD.

| Bit(s) | Init. | Type  | Description                                                     |

### 9.2.4.1.3 Uncorrectable Error Mask Register (0x108; RWS)

The Uncorrectable Error Mask register controls reporting of individual uncorrectable errors by device to the host bridge via a PCIe error message. A masked error (respective bit set in mask register) is not reported to the host bridge by an individual device. Note that there is a mask bit per bit of the Uncorrectable Error Status register.

| Bit(s) | Init. | Type  | Description                             |
|--------|-------|-------|-----------------------------------------|

#### 9.2.4.1.4 Uncorrectable Error Severity Register (0x10C; RWS)

The Uncorrectable Error Severity register controls whether an individual uncorrectable error is reported as a fatal error. An uncorrectable error is reported as fatal when the corresponding error bit in the severity register is set. If the bit is cleared, the corresponding error is considered non-fatal.

| Bit(s) | Init. | Type  | Description                                 |
|--------|-------|-------|---------------------------------------------|

| 31:26  | 0x0   | RsvdP | Reserved.                                   |

#### 9.2.4.1.5 Correctable Error Status Register (0x110; RW1CS)

The Correctable Error Status register reports error status of individual correctable error sources on a PCIe device. When an individual error status bit is set to 1b it indicates that a particular error occurred; software can clear an error status by writing a 1b to the respective bit. Register is cleared by LAN\_PWR\_GOOD.

| Bit(s) | Init. | Type  | Description                        |
|--------|-------|-------|------------------------------------|
| 0      | 0b    | RW1CS | <b>Receiver Error Status</b>       |

#### 9.2.4.1.6 Correctable Error Mask Register (0x114; RWS)

The Correctable Error Mask register controls reporting of individual correctable errors by device to the host bridge via a PCIe error message. A masked error (respective bit set in mask register) is not reported to the host bridge by an individual device. There is a mask bit per bit in the Correctable Error Status register.

| Bit(s) | Init. | Type  | Description                                                                                                                                                   |

| 15:12  | 0x0   | RsvdP | Reserved.                                                                                                                                                                                                                                                 |

### 9.2.4.1.8 Header Log Register (0x11C:128; RO)

The header log register captures the header for the transaction that generated an error. This register is 16 bytes.

| Bit(s) | Init. | Type | Description                                                                |
|--------|-------|------|----------------------------------------------------------------------------|
| 127:0  | 0x0   | ROS  | <b>Header Log Register</b><br>Header of the packet in error (TLP or DLLP). |

### 9.2.4.2 Serial Number Capability

The PCIe device serial number capability is an optional extended capability that can be implemented by any PCIe device. The device serial number is a read-only 64-bit value that is unique for a given PCIe device.

The X550 implements this capability on all the functions and returns the same value in both.

**Table 9-25. Serial Number Capability Structure**

| Byte Offset | Byte 3                               | Byte 2 | Byte 1        | Byte 0                           |
|-------------|--------------------------------------|--------|---------------|----------------------------------|
| 0x140       | Next Capability Offset               |        | Version (0x1) | Serial ID Capability ID (0x0003) |
| 0x144       | Serial Number Register (Lower Dword) |        |               |                                  |
| 0x148       | Serial Number Register (Upper Dword) |        |               |                                  |

Table 9-26 summarizes configuration sharing of the Serial ID Capability registers among the different PCI functions.

**Table 9-26. Configuration Sharing of the Serial Number Capability**

| Field                               | Sub-field              | Shared? | Replicated? | Comments |
|-------------------------------------|------------------------|---------|-------------|----------|

| Bit(s) | Init.           | Type | Description                                                                                                                                                                                                                                                    |
|--------|-----------------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 19:16  | 0x1             | RO   | <b>Capability Version</b><br>This field is a PCI-SIG defined version number that indicates the version of the capability structure present.<br><b>Note:</b> Must be set to 0x1 for this version of the specification.                                          |
| 31:20  | See description | RO   | <b>Next Capability Offset</b><br>This field contains the offset to the next PCIe capability structure or 0x000 if no other items exist in the linked list of capabilities.<br>See Table 9-22 and Table 9-11 for possible values of the next capability offset. |

### 9.2.4.2.2 Serial Number Registers (0x144:0x148; RO)

The Serial Number register is a 64-bit field that contains the IEEE defined 64-bit Extended Unique Identifier (EUI-64\*). The register at offset 0x144 holds the lower 32 bits and the register at offset 0x148 holds the higher 32 bits. The following figure details the allocation of register fields in the Serial Number register.

| Bit(s) | Type | Description                                                                                                                                                                                                                                         |
|--------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:0   | RO   | <b>PCIe Device Serial Number</b><br>This field contains the IEEE defined 64-bit EUI-64*. This identifier includes a 24-bit company ID value assigned by IEEE registration authority and a 40-bit extension identifier assigned by the manufacturer. |

The serial number uses the Ethernet MAC Address according to the following definition:

| Field                 | Company ID |        |        | Extension Identifier |        |                        |        |        |
|-----------------------|------------|--------|--------|----------------------|--------|------------------------|--------|--------|
| Order                 | Addr+0     | Addr+1 | Addr+2 | Addr+3               | Addr+4 | Addr+5                 | Addr+6 | Addr+7 |
| Most Significant Byte |            |        |        |                      |        | Least Significant Byte |        |        |
| Most Significant Bit  |            |        |        |                      |        | Least Significant Bit  |        |        |

The serial number can be constructed from the 48-bit Ethernet MAC Address in the following form:

| Field                  | Company ID |        |        | MAC Label |        | Extension identifier   |        |        |
|------------------------|------------|--------|--------|-----------|--------|------------------------|--------|--------|
| Order                  | Addr+0     | Addr+1 | Addr+2 | Addr+3    | Addr+4 | Addr+5                 | Addr+6 | Addr+7 |
| Most Significant Bytes |            |        |        |           |        | Least Significant Byte |        |        |
| Most Significant Bit   |            |        |        |           |        | Least Significant Bit  |        |        |

In this case, the MAC label is 0xFFFF.

For example, assume that the company ID is (Intel) 00-A0-C9 and the extension identifier is 23-45-67. In this case, the 64-bit serial number is:

| Field                 | Company ID |        |        | MAC Label |        | Extension Identifier   |        |        |
|-----------------------|------------|--------|--------|-----------|--------|------------------------|--------|--------|
| Order                 | Addr+0     | Addr+1 | Addr+2 | Addr+3    | Addr+4 | Addr+5                 | Addr+6 | Addr+7 |
|                       | 00         | A0     | C9     | FF        | FF     | 23                     | 45     | 67     |
| Most Significant Byte |            |        |        |           |        | Least Significant Byte |        |        |
| Most Significant Bit  |            |        |        |           |        | Least Significant Bit  |        |        |

The Ethernet MAC Address for the serial number capability is loaded from the NVM (not the same field that is loaded from NVM into the *RAL* and *RAH* registers). It is reflected in the *PCI\_SERL* and *PCI\_SERH* registers. The default value in case of no NVM is 0x0.

**Note:** The official document that defines EUI-64\* is:  
<http://standards.ieee.org/regauth/oui/tutorials/EUI64.html>

### 9.2.4.3 Alternate Routing ID Interpretation (ARI) Capability

To allow more than eight functions per endpoint without requesting an internal switch, as is usually needed in virtualization scenarios, the PCI-SIG defines a new capability that allows a different interpretation of the *Bus*, *Device*, and *Function* fields. The capability is exposed when the *PCI\_CAPSUP.ARI\_EN* bit is set from NVM.

The ARI capability structure is as follows:

**Table 9-27. ARI Capability Structure**

| Byte Offset | Byte 3                 | Byte 2        | Byte 1                     | Byte 0 |
|-------------|------------------------|---------------|----------------------------|--------|
| 0x150       | Next Capability Offset | Version (0x1) | ARI Capability ID (0x000E) |        |
| 0x154       | ARI Control Register   |               | ARI Capabilities           |        |

Table 9-28 summarizes configuration sharing of the ARI Capability registers among the different PCI functions.

**Table 9-28. Configuration Sharing of the ARI Capability**

| Field                               | Sub-field              | Shared? | Replicated? | Comments |
|-------------------------------------|------------------------|---------|-------------|----------|
| Enhanced Capability Header Register | Extended Capability ID | x       |             |          |
|                                     | Capability Version     | x       |             |          |
|                                     | Next Capability Offset |         | x           |          |
| ARI capability Register             | Next Function Pointer  |         | x           |          |

#### 9.2.4.3.1 PCIe ARI Header Register (0x150; RO)

| Field                  | Bit(s) | Init.           | Type | Description                                                                                                                                                                                       |
|------------------------|--------|-----------------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ID                     | 15:0   | 0xE             | RO   | <b>PCIe Extended Capability ID</b><br>PCIe extended capability ID for the alternative RID interpretation.                                                                                         |
| Version                | 19:16  | 0x1             | RO   | <b>Capability Version</b><br>This field is a PCI-SIG defined version number that indicates the version of the capability structure present.<br>Must be 0x1 for this version of the specification. |
| Next Capability Offset | 31:20  | See description | RO   | <b>Next Capability Offset</b><br>This field contains the offset to the next PCIe extended capability structure. See Table 9-22. and Table 9-11 for possible values of the next capability offset. |

### 9.2.4.3.2 PCIe ARI Capabilities and Control Register (0x154; RO)

| Field    | Bit(s) | Init.                                     | Type | Description                                                                                                                                                                                                                                 |
|----------|--------|-------------------------------------------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Reserved | 7:0    | 0x2                                       | RO   | Reserved.                                                                                                                                                                                                                                   |
| NFP      | 15:8   | 0x1 (func 0)<br>0x0 (func 1) <sup>1</sup> | RO   | <b>Next Function Pointer</b><br>This field contains the pointer to the next physical function configuration space or 0x0000 if no other items exist in the linked list of functions. Function 0 is the start of the link list of functions. |
| Reserved | 31:16  | 0x0                                       | RO   | Reserved.                                                                                                                                                                                                                                   |

1. Even if port 0 and port 1 are switched or function zero is a dummy function, this register should keep its attributes according to the function number. If LAN1 is disabled, the value of this field in function zero should be zero.

### 9.2.4.4 IOV Capability

**Note:** This capability structure is not exposed in a dummy function.

This is a structure used to support the SR-IOV capabilities reporting and control. The capability is exposed when the PCI\_CAPSUP.IOV\_EN bit is set from NVM and the PCI\_CNF2.NUM\_VFS is non zero.

**Table 9-29. IOV Capability Structure**

| Byte Offset | Byte 3                               | Byte 2                        | Byte 1        | Byte 0                     |
|-------------|--------------------------------------|-------------------------------|---------------|----------------------------|
| 0x160       | Next Capability Offset (0x0)         |                               | Version (0x1) | IOV Capability ID (0x0010) |
| 0x164       | SR IOV Capabilities                  |                               |               |                            |
| 0x168       | SR IOV Status                        |                               |               | SR IOV Control             |

|-----------------------|--------|-------|----------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VFE                   | 0      | 0b    | RW                                                                                     | <b>VF Enable/Disable</b><br>VF Enable manages the assignment of VFs to the associated PF. If <i>VF Enable</i> is set to 1b, VFs must be enabled, associated with the PF, and exists in the PCIe fabric. When enabled, VFs must respond to and can issue PCIe transactions following all other rules for PCIe functions.<br>If set to 0b, VFs must be disabled and not visible in the PCIe fabric; VFs cannot respond to or issue PCIe transactions.<br>In addition, if <i>VF Enable</i> is cleared after having been set, all of the VFs must no longer:<br><ul style="list-style-type: none"> <li>• Issue PCIe transactions</li> <li>• Respond to configuration space or memory space accesses.</li> </ul> The behavior must be as if an FLR was issued to each of the VFs. Specifically, VFs must not retain any context after <i>VF Enable</i> has been cleared. Any errors already logged via PF error reporting registers, remain logged. However, no new VF errors must be logged after <i>VF Enable</i> is cleared. |
| Reserved              | 2:1    | 00b   | RO                                                                                     | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| VF MSE                | 3      | 0b    | RW                                                                                     | <b>Memory Space Enable for Virtual Functions</b><br>VF MSE controls memory space enable for all VFs associated with this PF as with the <i>Memory Space Enable</i> bit in a functions PCI command register. The default value for this bit is 0b.<br>When VF Enable is 1, virtual function memory space access is permitted only when VF MSE is Set. VFs must follow the same error reporting rules as defined in the base specification if an attempt is made to access a virtual functions memory space when VF Enable is 1 and VF MSE is zero.<br>Implementation Note: Virtual functions memory space cannot be accessed when VF Enable is zero. Thus, VF MSE is “don't care” when VF Enable is zero, however, software may choose to set VF MSE after programming the VF BARn registers, prior to setting VF Enable to 1.                                                                                                                                                                                              |
| ARI Capable Hierarchy | 4      | 0b    | RW<br>(first function where SR-IOV is enabled)<br>ROS<br>(other function) <sup>1</sup> | <b>ARI Capable Hierarchy</b><br>The X550 is permitted to locate VFs in function numbers 8 to 255 of the captured bus number.<br>This field is R/W in the lowest numbered PF. Other functions use the PF0 value as sticky.<br><b>Note:</b> If either ARI Capable Hierarchy Preserved is set (see <a href="#">Section 9.2.4.4.2</a> ) or No_Soft_Reset is Set, a power state transition of this PF from D3hot to D0 does not affect the value of this bit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Reserved              | 31:5   | 0x0   | RO                                                                                     | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

1. Even if port 0 and port 1 are switched or function zero is a dummy function, this field should keep its attributes according to the function number.

#### 9.2.4.4.4 PCIe SR-IOV Max/Total VFs Register (0x16C; RO)

| Field      | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                      |
|------------|--------|-------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| InitialVFs | 15:0   | 64    | RO   | <b>InitialVFs</b><br>Indicates the number of VFs that are initially associated with the PF. If <i>VF Migration Capable</i> is cleared, this field must contain the same value as TotalVFs. In the X550 this parameter is equal to the TotalVFs in this register. |
| TotalVFs   | 31:16  | 64    | RO   | <b>TotalVFs</b><br>Defines the maximum number of VFs that can be associated with the PF. This field is loaded from the Max VFs field in the NVM. Reflected in <code>PCI_CNFG2.TOTAL_VFS</code> .                                                                 |

#### 9.2.4.4.5 PCIe SR-IOV Num VFs Register (0x170; RW)

| Field    | Bit(s) | Init.                                     | Type | Description                                                                                                                                                                                                                                                                                                |
|----------|--------|-------------------------------------------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NumVFs   | 15:0   | 0x0                                       | RW   | <b>Num VFs</b><br>Defines the number of VFs software has assigned to the PF. Software sets NumVFs to any value between one and the TotalVFs as part of the process of creating VFs. NumVFs VFs must be visible in the PCIe fabric after both NumVFs is set to a valid value <i>VF Enable</i> is set to 1b. |
| FDL      | 23:16  | 0x0 (func 0)<br>0x1 (func 1) <sup>1</sup> | RO   | <b>Function Dependency Link</b><br>Defines dependencies between physical functions allocation. In the X550 there are no constraints.                                                                                                                                                                       |
| Reserved | 31:24  | 0x0                                       | RO   | Reserved.                                                                                                                                                                                                                                                                                                  |

1. Even if port 0 and port 1 are switched or function zero is a dummy function, this register should keep its attributes according to the function number.

#### 9.2.4.4.6 PCIe SR-IOV VF RID Mapping Register (0x174; RO)

| Field | Bit(s) | Init.            | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------|--------|------------------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FVO   | 15:0   | 0x180            | RO   | <b>First VF offset</b><br>Defines the requestor ID (RID) offset of the first VF that is associated with the PF that contains this capability structure. The first VFs 16-bit RID is calculated by adding the contents of this field to the RID of the PF containing this field.<br>The content of this field is valid only when <i>VF Enable</i> is set. If <i>VF Enable</i> is 0b, the contents are undefined.<br>If the <i>ARI Enable</i> bit is set, this field changes to 0x80. |
| VFS   | 31:16  | 0x2 <sup>1</sup> | RO   | <b>VF stride</b><br>Defines the requestor ID (RID) offset from one VF to the next one for all VFs associated with the PF that contains this capability structure. The next VFs 16-bit RID is calculated by adding the contents of this field to the RID of the current VF.<br>The contents of this field is valid only when <i>VF Enable</i> is set and <i>NumVFs</i> is non-zero. If <i>VF Enable</i> is 0b or if <i>NumVFs</i> is zero, the contents are undefined.               |

1. See [Section 7.8.2.6.1](#).

#### 9.2.4.4.7 PCIe SR-IOV VF Device ID Register (0x178; RO)

| Field    | Bit(s) | Init.  | Type | Description                                                                                                                                                                                                       |
|----------|--------|--------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DEVID    | 31:16  | 0x1565 | RO   | <b>VF Device ID</b><br>This field contains the device ID that should be presented for every VF to the Virtual Machine (VM).<br>The value of this field can be read from the <i>IOV Control Word 2</i> in the NVM. |
| Reserved | 15:0   | 0x0    | RO   | Reserved.                                                                                                                                                                                                         |

#### 9.2.4.4.8 PCIe SR-IOV Supported Page Size Register (0x17C; RO)

| Field               | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------|--------|-------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Supported Page Size | 31:0   | 0x553 | RO   | <b>Supported Page Size</b><br>For PFs that supports the stride-based BAR mechanism, this field defines the supported page sizes. This PF supports a page size of $2^{(n+12)}$ if bit <i>n</i> is set. For example, if bit 0 is Set, the Endpoint (EP) supports 4KB page sizes. Endpoints are required to support 4 KB, 8 KB, 64 KB, 256 KB, 1 MB and 4 MB page sizes. All other page sizes are optional. |

#### 9.2.4.4.9 PCIe SR-IOV System Page Size Register (0x180; RW)

| Field     | Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------|--------|-------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Page Size | 31:0   | 0x1   | RW   | <b>Page Size</b><br>This field defines the page size the system uses to map the PF's and associated VFs' memory addresses. Software must set the value of the <i>System Page Size</i> to one of the page sizes set in the <i>Supported Page Sizes</i> field. As with <i>Supported Page Sizes</i> , if bit <i>n</i> is set in <i>System Page Size</i> , the PF and its associated VFs are required to support a page size of $2^{(n+12)}$ . For example, if bit 1 is set, the system is using an 8 KB page size. The results are undefined if more than one bit is set in <i>System Page Size</i> . The results are undefined if a bit is set in <i>System Page Size</i> that is not set in <i>Supported Page Sizes</i> .<br>When <i>System Page Size</i> is set, the PF and associated VFs are required to align all BAR resources on a <i>System Page Size</i> boundary. Each BAR size, including <i>VF BAR<sub>n</sub> Size</i> (described later) must be aligned on a <i>System Page Size</i> boundary. Each BAR size, including <i>VF BAR<sub>n</sub> Size</i> must be sized to consume a multiple of <i>System Page Size</i> bytes. All fields requiring page size alignment within a function must be aligned on a <i>System Page Size</i> boundary. <i>VF Enable</i> must be zero when <i>System Page Size</i> is set. The results are undefined if <i>System Page Size</i> is set when <i>VF Enable</i> is set. |

#### 9.2.4.4.10 PCIe SR-IOV BAR 0 — Low Register (0x184; RW)

| Field    | Bit(s) | Init. | Type | Description                                                                                                                                                    |
|----------|--------|-------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Mem      | 0      | 0b    | RO   | <b>Memory</b><br>0b = Indicates memory space.                                                                                                                  |
| Mem Type | 2:1    | 10b   | RO   | <b>Memory Type</b><br>Indicates the address space size.<br>10b = 64-bit.<br>This bit is loaded from the NVM. It is reflected in the <i>PCI_VFSUP</i> register. |

#### 9.2.4.4.14 PCIe SR-IOV BAR 3 — High Register (0x194; RW)

| Field      | Bit(s) | Init. | Type | Description       |
|------------|--------|-------|------|-------------------|
| BAR4 — MSB | 31:0   | 0x0   | RW   | MSB part of BAR3. |

#### 9.2.4.4.15 PCIe SR-IOV BAR 5 Register (0x198; RO)

| Field | Bit(s) | Init. | Type | Description          |
|-------|--------|-------|------|----------------------|
| BAR5  | 31:0   | 0x0   | RO   | This BAR is not used |

#### 9.2.4.4.16 PCIe SR-IOV VF Migration State Array Offset Register (0x19C; RO)

| Field    | Bit(s) | Init. | Type | Description |
|----------|--------|-------|------|-------------|
| Reserved | 31:0   | 0x0   | RO   | Reserved.   |

#### 9.2.4.5 TPH Requester Capability

The TPH Requester capability is an optional extended capability to support TLP Processing Hints. [Table 9-31](#) lists the TPH extended capability structure for PCIe devices.

**Table 9-31. TPH Requester Capability Structure**

| Byte Offset | Byte 3                            | Byte 2 | Byte 1        | Byte 0                     |  |
|-------------|-----------------------------------|--------|---------------|----------------------------|--|
| 0x1A0       | Next Capability Offset            |        | Version (0x1) | TPH Capability ID (0x0017) |  |
| 0x1A4       | TPH Requester Capability Register |        |               |                            |  |
| 0x1A8       | TPH Requester Control Register    |        |               |                            |  |

[Table 9.2.4.5.3](#) summarizes configuration sharing of the TPH Requester Capability registers among the different PCI functions.

**Table 9-32. Configuration Sharing of the TPH Requester Capability**

| Field                               | Sub-field              | Shared? | Replicated? | Comments                                          |
|-------------------------------------|------------------------|---------|-------------|---------------------------------------------------|
| Enhanced Capability Header Register | Extended Capability ID | x       |             |                                                   |

### 9.2.4.6 Access Control Services (ACS) Capability

The PCIe ACS defines a set of control points within a PCIe topology to determine whether a TLP should be routed normally, blocked, or redirected. ACS is applicable to RCs, switches, and multifunction devices and is not exposed in Single function mode (when function 1 is disabled). The capability is exposed when the PCI\_CAPSUP.ACS\_EN bit is set from NVM.

The ACS Capability structure is shared and exposed to all PFs.

Table 9-33 lists the PCIe ACS extended capability structure for PCIe devices.

**Table 9-33. ACS Capability Structure**

| Byte Offset | Byte 3                     | Byte 2 | Byte 1                        | Byte 0 |

## 9.2.4.7 Latency Tolerance Reporting (LTR) Capability

The Latency Tolerance Reporting Capability is an optional Extended Capability that allows software to provide platform latency information to devices with upstream ports (Endpoints and Switches). This capability structure is required if the device supports Latency Tolerance Reporting (LTR). The capability is exposed when the PCI\_CAPSUP.LTR\_EN bit is set from NVM.

The LTR Capability structure is implemented only in Function 0 even when Function 0 is a dummy function, and controls the component's Link behavior on behalf of all the Functions of the device

Table 9-34 lists the PCIe LTR extended capability structure for PCIe devices.

**Table 9-34. LTR Capability Structure**

| Byte Offset | Byte 3                                 | Byte 2 | Byte 1                     | Byte 0 |

### 9.2.4.8 Secondary PCI Express Extended Capability

The Secondary PCI Express Extended Capability structure is required for all Ports and RCRBs that support a Link speed of 8.0 GT/s or higher. For Multi-Function Upstream Ports, this capability must be implemented in Function 0 and must not be implemented in other Functions. The capability is exposed when the PCI\_CAPSUP.SEC\_EN bit is set from NVM.

Table 9-35 lists the Secondary PCI Express extended capability structure for PCIe devices.

**Table 9-35. Secondary PCI Express Extended Capability Structure**

| Byte Offset | Byte 3                                                      | Byte 2 | Byte 1 | Byte 0 |

| 31:2   | 0x0   | RsvdZ    | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                |

### 9.2.4.8.3 Lane Error Status Register (0x1D8)

The Lane Error Status register consists of a 32-bit vector, where each bit indicates if the corresponding PCI Express Lane detected an error.

| Bit(s) | Init. | Type  | Description                                                                                                                                                                                                                                                                                            |
|--------|-------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0    | 0x0   | RW1CS | <b>Lane Error Status Bits</b><br>Each bit indicates if the corresponding Lane detected a Lane-based error. A value of 1b indicates that a Lane based-error was detected on the corresponding Lane Number.<br>The default value of this field is 0b.<br>This field is intended for debug purposes only. |
| 31:8   | 0x0   | RsvdZ | Reserved.                                                                                                                                                                                                                                                                                              |

### 9.2.4.8.4 Lane Equalization Control Register (0x1DC: 0x1E3)

The Equalization Control register consists of control fields required for per Lane equalization and number of entries in this register are sized by Maximum Link Width.

## 9.2.5 Driver Forward Compatibility Register (0x94; RO)

This register is an advisory register that returns a fixed value indicating the type of software device driver class needed for this device.

| Bit(s) | Init.  | Type | Description                                                                                                    |
|--------|--------|------|----------------------------------------------------------------------------------------------------------------|
| 15:0   | 0xFFFF | RO   | <b>Pointer to Admin Queues</b><br>A value of 0xFFFF indicates that this device does not support admin. queues. |
| 19:16  | 0x0    | RO   | <b>Status</b><br>Not implemented in the X550.                                                                  |
| 31:20  | 0xA0A  | RO   | <b>Signature</b><br>Signature indicating a driver class register.                                              |

## 9.2.6 CSR Access Via Configuration Address Space

The registers described in the section are not part of the PCI Express standard configuration and can be used to access the CSR space before memory BARs are allocated. When this mechanism is used, there is no need to expose an I/O BAR for pre boot operation.

**Note:** These registers are not available for dummy functions.

### 9.2.6.1 IOADDR Register (0x98; R/W)

This is a read/write register. Each function has its own IOADDR register. Functionality is the same in all functions. Register is cleared at power-up (LAN\_PWR\_GOOD) or PCIe reset.

**Note:** When functioning in a D3 state, software should not attempt to access CSRs via the IOADDR and IODATA registers.

| Bit(s) | Init. | Type             | Description                                                                                                                                                                                                                                                                                                                                                               |
|--------|-------|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 30:0   | 0x0   | R/W <sup>1</sup> | <b>Internal Register or Internal Memory location Address</b><br>0x00000-0x1FFFF = Internal registers and memories<br>0x20000-0x7FFFFFFF = Undefined                                                                                                                                                                                                                       |
| 31     | 0b    | R/W              | <b>Configuration IO Access Enable</b><br>0b = CSR configuration read or write disabled.<br>1b = CSR configuration read or write enabled.<br>When this bit is set, accesses to the IODATA register actually generate transactions to the X550. Otherwise, accesses to the IODATA register are don't-cares (writes are discarded silently, reads return arbitrary results). |

1. In the event that the PCI\_CAPSUP.CSR\_CONF\_EN bit is cleared, accesses to the IOADDR register via the configuration address space is ignored and has no effect on the register and the CSRs referenced by the IOADDR register.

### 9.2.6.2 IODATA Register (0x9C; R/W)

This is a read/write register. Each function has its own IODATA register. Functionality is the same in all functions. Register is cleared at power-up (LAN\_PWR\_GOOD) or PCIe reset.

| Bit(s) | Init. | Type             | Description                                                                                                                                                                                    |
|--------|-------|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0   | 0x0   | R/W <sup>1</sup> | Data field for reads or writes to the Internal register or internal memory location as identified by the current value in IOADDR. All 32 bits of this register can be read from or written to. |

1. In the event that the *IO\_by\_cfg* bit in the *PCIe Init Configuration 2* EEPROM word is cleared, access to the IODATA register via the configuration address space is ignored and has no effect on the register and the CSRs referenced by the IOADDR register.

## 9.3 Virtual Functions Configuration Space

The configuration space reflected to each of the VF is a sparse version of the physical function configuration space. [Table 9-36](#) describes the behavior of each register in the VF configuration space.

**Table 9-36. VF PCIe Configuration Space**

| Section                 | Offset  | Name                  | VF behavior | Notes                                   |

## 9.3.2 PCI Capabilities

### 9.3.2.1 MSI-X Capability

The only registers with a different layout than the PF for MSI-X, is the control register.

**Note:** The message address and data registers in enhanced mode use the first MSI-X entry of each VF in the regular MSI-X table.

See [Section 8.3.4.1](#) for details of the MSI-X registers in BAR 3 of the VF.

#### 9.3.2.1.1 VF MSI-X Control Register (0x72; RW)

| Bit(s) | Init.            | Type | Description                   |
|--------|------------------|------|-------------------------------|
| 10:0   | 0x2 <sup>1</sup> | RO   | <b>TS</b><br>Table Size.      |
| 13:11  | 000b             | RO   | Reserved.                     |
| 14     | 0b               | RW   | <b>Mask</b><br>Function Mask. |
| 15     | 0b               | RW   | <b>En</b><br>MSI-X Enable.    |

1. Default value is read from the NVM. This field is loaded from the PCI\_CNF2.MSI\_X\_VF\_N register field.

### 9.3.2.1.2 MSI-X Table Offset Register (0x74; RW)

| Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                   |
|--------|-------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2:0    | 011b  | RO   | <b>Table BIR</b><br>Indicates which one of a function's BARs, beginning at 0x10 in the configuration space, is used to map the function's MSI-X table into the memory space. BIR values: 0...5 correspond to BARs 0x10...0x24, respectively. BIR equals 3 to indicate BAR 3 and 4 are used for MSI-X vectors. |
| 31:3   | 0x0   | RO   | <b>Table Offset</b><br>Used as an offset from the address contained in one of the function's BARs to point to the base of the MSI-X table. The lower three <i>Table BIR</i> bits are masked off (set to 0b) by software to form a 32-bit Qword-aligned offset.<br>This field is read only.                    |

### 9.3.2.1.3 MSI-X PBA Register (0x78; RO)

| Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                                                                                              |
|--------|-------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2:0    | 011b  | RO   | <b>PBA BIR</b><br>Indicates which one of a function's BARs, located beginning at 0x10 in configuration space, is used to map the function's MSI-X PBA into memory space. BIR values: 0...5 correspond to BARs 0x10...0x24, respectively. BIR equals 3 to indicate BAR 3 and 4 are used for MSI-X PBA.                                                                    |
| 31:3   | 0x400 | RO   | <b>PBA Offset</b><br>Used as an offset from the address contained by one of the function's BARs to point to the base of the MSI-X PBA. The lower three <i>PBA BIR</i> bits are masked off (set to zero) by software to form a 32-bit Qword-aligned offset.<br>This value is changed by hardware to be half of the value programmed to the IOV System Page Size register. |

## 9.3.2.2 PCIe Capability Registers

The Device Control and Device Status registers have some fields which are specific per VF.

### 9.3.2.2.1 VF Device Control Register (0xA8; RW)

| Bit(s) | Init. | Type | Description                                                  |
|--------|-------|------|--------------------------------------------------------------|
| 0      | 0b    | RO   | <b>Correctable Error Reporting Enable</b><br>Zero for VFs.   |
| 1      | 0b    | RO   | <b>Non-Fatal Error Reporting Enable</b><br>Zero for VFs.     |
| 2      | 0b    | RO   | <b>Fatal Error Reporting Enable</b><br>Zero for VFs.         |
| 3      | 0b    | RO   | <b>Unsupported Request Reporting Enable</b><br>Zero for VFs. |
| 4      | 0b    | RO   | <b>Enable Relaxed Ordering</b><br>Zero for VFs.              |
| 7:5    | 000b  | RO   | <b>Max Payload Size</b><br>Zero for VFs.                     |
| 9:8    | 00b   | RO   | Reserved.                                                    |
| 10     | 0b    | RO   | <b>Auxiliary Power PM Enable</b><br>Zero for VFs.            |
| 11     | 0b    | RO   | <b>Enable No Snoop</b><br>Zero for VFs.                      |

| Bit(s) | Init. | Type | Description                                                  |
|--------|-------|------|--------------------------------------------------------------|
| 14:12  | 000b  | RO   | <b>Max Read Request Size</b><br>Zero for VFs.                |
| 15     | 0b    | RW   | <b>Initiate Function Level Reset</b><br>Specific to each VF. |

### 9.3.2.2.2 VF Device Status Register (0xAA; RW1C)

| Bit(s) | Init. | Type | Description                                                                                                                                                                                                                                                                                     |
|--------|-------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0      | 0b    | RW1C | <b>Correctable Detected</b><br>Indicates status of correctable error detection. Zero for VF.                                                                                                                                                                                                    |
| 1      | 0b    | RW1C | <b>Non-Fatal Error Detected</b><br>Indicates status of non-fatal error detection. Zero for VF.                                                                                                                                                                                                  |
| 2      | 0b    | RW1C | <b>Fatal Error Detected</b><br>Indicates status of fatal error detection. Zero for VF.                                                                                                                                                                                                          |
| 3      | 0b    | RW1C | <b>Unsupported Request Detected</b><br>Indicates that the X550 received an unsupported request. This field is identical in all functions. The X550 cannot distinguish which function caused an error. Zero for VF.                                                                              |
| 4      | 0b    | RO   | <b>Aux Power Detected</b><br>Zero for VFs.                                                                                                                                                                                                                                                      |
| 5      | 0b    | RO   | <b>Transaction Pending</b><br>Specific per VF. When set, indicates that a particular function (PF or VF) has issued non-posted requests that have not been completed. A function reports this bit cleared only when all completions for any outstanding non-posted requests have been received. |
| 15:6   | 0x0   | RO   | Reserved.                                                                                                                                                                                                                                                                                       |

## 9.3.3 PCIe Extended Capabilities

### 9.3.3.1 AER Registers

The following registers in the AER capability have a different behavior in a VF function.

Unlike the PF AER registers, these registers are not sticky since the VF is reset on FLR and on in-band reset.

#### 9.3.3.1.1 Uncorrectable Error Status Register (0x104; RW1C)

| Bit(s) | Init. | Type | Description                                  |
|--------|-------|------|----------------------------------------------|
| 3:0    | 0x0   | RO   | Reserved.                                    |
| 4      | 0b    | RO   | <b>Data Link Protocol Error Status</b>       |
| 5      | 0b    | RO   | <b>Surprise Down Error Status (Optional)</b> |
| 11:6   | 0x0   | RO   | Reserved.                                    |
| 12     | 0b    | RW1C | <b>Poisoned TLP Status</b>                   |
| 13     | 0b    | RO   | <b>Flow Control Protocol Error Status</b>    |
| 14     | 0b    | RW1C | <b>Completion Timeout Status</b>             |
| 15     | 0b    | RW1C | <b>Completer Abort Status</b>                |
| 16     | 0b    | RW1C | <b>Unexpected Completion Status</b>          |

| Bit(s) | Init. | Type | Description                                                                             |
|--------|-------|------|-----------------------------------------------------------------------------------------|
| 17     | 0b    | RO   | <b>Receiver Overflow Status</b>                                                         |
| 18     | 0b    | RO   | <b>Malformed TLP Status</b>                                                             |
| 19     | 0b    | RO   | <b>ECRC Error Status</b>                                                                |
| 20     | 0b    | RW1C | <b>Unsupported Request Error Status</b><br>When caused by a function that claims a TLP. |
| 21     | 0b    | RO   | <b>ACS Violation Status</b>                                                             |
| 31:22  | 0x0   | RO   | Reserved.                                                                               |

### 9.3.3.1.2 Correctable Error Status Register (0x110; RW1C)

The Correctable Error Status register reports error status of individual correctable error sources on a PCIe device. When an individual error status bit is set to 1b it indicates that a particular error occurred; software can clear an error status by writing a 1b to the respective bit.

| Bit(s) | Init. | Type | Description                            |
|--------|-------|------|----------------------------------------|
| 0      | 0b    | RW1C | <b>Receiver Error Status</b>           |
| 5:1    | 0x0   | RO   | Reserved.                              |
| 6      | 0b    | RW1C | <b>Bad TLP Status</b>                  |
| 7      | 0b    | RW1C | <b>Bad DLLP Status</b>                 |
| 8      | 0b    | RW1C | <b>REPLAY_NUM Rollover Status</b>      |
| 11:9   | 000b  | RO   | Reserved.                              |
| 12     | 0b    | RW1C | <b>Replay Timer Timeout Status</b>     |
| 13     | 0b    | RW1C | <b>Advisory Non-Fatal Error Status</b> |
| 31:14  | 0x0   | RO   | Reserved.                              |

## 10.0 PHY Registers

### 10.1 Introduction

This chapter describes the PHY registers in the X550, which are accessible via the internal MDIO interface. Refer to [Section 3.7.2](#).

The PHY is internally divided into a series of MDIO Manageable Devices (MMDs), each of which performs a logical function as per the 10GBASE-T standard:

- MMD #1 contains the PMA, which is basically the analog front-end of the chip ([Section 10.2](#)).
- MMD #3 contains the PCS, which handles the 10GBASE-T transmission frame coding and decoding, including the 128-DSQ and LDPC work ([Section 10.3](#)).
- MMD #7 contains the auto-negotiation function ([Section 10.4](#)).
- MMD #29 contains the controls for the GbE and 100 Mb/s PCS machinery ([Section 10.5](#)).
- MMD# 30 contains the global control functionality for the PHY, including the embedded micro controller ([Section 10.6](#)).

#### 10.1.1 PHY Register Structure

A map of these regions is shown in [Table 10-1](#).

**Table 10-1. MMD Device Addresses**

| 5-bit Device Address (Hex) | MMD Name                   |
|----------------------------|----------------------------|
| 0                          | Reserved                   |
| 1                          | PMA/PMD (128 DSQ)          |
| 2                          | Reserved                   |
| 3                          | PCS (64/65B coder/decoder) |
| 4                          | Reserved                   |
| 5 → 6                      | Reserved                   |
| 7                          | Auto-negotiation           |
| 8 → 1C                     | Reserved                   |
| 1D                         | Clause 22 Extension        |
| 1E                         | Global                     |
| 1F                         | Reserved                   |

Any attempt to read from the reserved MMD addresses returns a value of 0x00, and any writes to these addresses have no effect.

## 10.1.2 Format and Nomenclature

PHY registers within the device are referenced in the format:

Region . Register . Bit

where **Region** corresponds to the MMD region being addressed, **Register** corresponds to the register within the MMD region, and **Bit** is the bit within the register. All registers within the MDIO register space are 16 bits. The address of the register is the 16 bit MDIO address.

All read and write operation are word based, which means that the entire 16 bit register is read or written (versus individual bits). Within the MDIO register space, there are several different bit types. A list of these bit types are listed in [Table 10-2](#).

**Table 10-2. Field Types within the MDIO Register Space**

| Type | Description                                                                                                                                                                                                                                         |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LL   | <b>Latching Low</b><br>If the condition the bit is monitoring goes low, this bit latches low, generates a maskable interrupt, and stays low until read. Reading this bit resets it to one. This bit is read-only.                                   |
| LH   | <b>Latching High</b><br>If the condition the bit is monitoring goes high, this bit latches high, generates a maskable interrupt, and stays high until read. Reading this bit resets it to zero. This bit is read-only.                              |
| LRF  | <b>Latch Rising or Falling</b><br>Set high on either a rising or falling edge. If a transition occurs, this bit latches high, generates a maskable interrupt, and stays high until read. Reading this bit resets it to zero. This bit is read-only. |
| PD   | <b>Provisionable Defaults</b><br>Indicates that the default value associated with this field is provisionable.                                                                                                                                      |
| RO   | <b>Read-Only</b><br>Read-only field. Writes are ignored.                                                                                                                                                                                            |
| ROS  | <b>Read Only Static</b><br>Read-only static field. The same value is always returned. Writes are ignored.                                                                                                                                           |
| RSV  | <b>Reserved</b><br>Reserved for future use.                                                                                                                                                                                                         |
| RW   | <b>Read/Write</b><br>Field can be both read from and written to.                                                                                                                                                                                    |
| SC   | <b>Self-Clearing</b><br>A read/write register which resets itself upon completion of an action.                                                                                                                                                     |
| SCT  | <b>Saturating Counter</b><br>A read-only counter that saturates at the limit, and is cleared on read.                                                                                                                                               |
| SCTL | <b>Saturating Counter LSW</b><br>The Least Significant Word of a Saturating Counter. This register clears the pair to zero on read and snapshots the mate MSW to shadow memory, awaiting read.                                                      |
| SCTM | <b>Saturating Counter MSW</b><br>The Most Significant Word of a Saturating Counter. Reading this completes the read process of the register pair.                                                                                                   |

## 10.1.3 Structure

The following structure is used for registers:

1. All Clause 45 registers (registers defined in Clause 45) are placed in their respective areas within the MMDs as specified.
2. Intel specific registers associated with each of the Clause 45 MMDs are placed in the Intel specific area beginning at 0xC000, according to the register map listed in [Table 10-3](#).

**Table 10-3. Register Layout**

| Base Offset (Hex) | Description                     |
|-------------------|---------------------------------|
| C000              | Tx & Overall MMD Control        |
| C400              | Tx & Overall MMD Provisioning   |
| C800              | Tx & Overall MMD State          |
| CC00              | Tx & Overall MMD Alarms         |
| D000              | Standard Interrupt Mask         |
| D400              | Tx & Overall MMD Interrupt Mask |
| D800              | Tx & Overall MMD Debug          |
| DC00              | Reserved                        |
| E000              | Rx Control                      |
| E400              | Rx Provisioning                 |
| E800              | Rx State                        |
| EC00              | Rx Alarms                       |
| F000              | Standard Interrupt Mask         |
| F400              | Rx Interrupt Mask               |
| F800              | Rx Debug                        |
| FC00              | Global Interrupt Flags          |

The table is split into a transmit portion, and a receive portion, with the transmit portion also containing any overall Intel specific registers for the MMD. In this table, the following definitions apply:

**Table 10-4. Terms Used within the Register Layout**

| Term                          | Definition                                                            |
|-------------------------------|-----------------------------------------------------------------------|
| Control                       | Action bits that affect the operation of the MMD, such as reset.      |
| Provisioning                  | Static provisioning bits that control the behavior of the MMD.        |
| State                         | Bits that reflect the state of the MMD.                               |
| Alarm                         | Bits that can generate maskable interrupts.                           |
| Standard Interrupt Mask       | Interrupt masks for alarm bits defined in the Clause 45 register set. |
| Intel Specific Interrupt Mask | Interrupt masks for Intel Specific alarms.                            |

3. Interrupts are handled in an hierarchical fashion, with the PHY top level interrupt indication being reported in the EICR register. Below this are two maskable interrupt trees: one composed of standard interrupts, and one composed of Intel defined interrupts. The top level summary register for these trees resides at the end of the register space in MMD #30 - the Global PHY Standard Interrupt Flags (1E.FC00). Feeding this are interrupt registers from each of the individual MMDs.
  - a. The standard interrupt tree is designed so that the source of any interrupt can be determined in a maximum of two MDIO reads.
  - b. The Intel defined interrupt tree requires at most three MDIO reads to determine the source of an interrupt.
  - c. All interrupts are maskable, whether they are from the Standard interrupt tree, or from the Intel Specific interrupt tree.

### 10.1.4 PHY Registers and Documentation

The PHY registers for X550 are provided in the following tables, listed by the numerical order of their MMD address.

## 10.2 PMA Registers

### 10.2.1 PMA Standard Control 1: Address 1.0

| Bit | Name                         | Type     | Default | Description                                                                                                                                                                                                                                                                   |
|-----|------------------------------|----------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | Loopback                     | RW<br>PD | 0b      | <b>Loopback</b><br>This enables the PMA analog system loopback.<br>0b = Normal operation.<br>1b = Enable loopback mode.                                                                                                                                                       |
| 1   | Reserved                     | RSV      |         | Reserved. Do not modify.                                                                                                                                                                                                                                                      |

### 10.4.12 Auto-Negotiation Extended Next Page Transmit Register: Address 7.16

**Note:** This register is used in conjunction with Bit 7.C400.5 and registers 7.17 and 7.18 to hard-provision the auto-negotiation extended next page that is sent. By using this register, it is possible to hard code the 1 GbE and 10 GbE capabilities.

| Bit | Name                     | Type     | Default | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| 5:2 | Extra Page Count [3:0]    | RW PD | 0x4     | <b>Extra Page Count</b><br>Number of extra pages to send at the end of the auto-negotiation sequence when the link partner is a legacy GbE PHY. Intervals between pages for GbE PHYs might be much longer. If this is the case, the link partner might still be in auto-negotiation when the X550 starts its training. This might confuse the link partner MDI/MDI-X state machine. Sending extra pages seems to correct this problem. |
| 6   | WoL Enable                | RW PD | 0b      | <b>WoL Enable</b><br>Setting this bit enables WoL operation. In this state, power is minimized by turning off all interfaces except the MDI receive path and the MDIO interface.                                                                                                                                                                                                                                                       |

## 10.6.5 Global Standard Vendor Devices in Package 2: Address 1E.6

| Bit | Name                              | Type | Default | Description                                                                                                                                                                                                                           |
|-----|-----------------------------------|------|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| C:0 | Reserved                          | RSV  |         | Reserved. Do not modify.                                                                                                                                                                                                              |
| D   | Clause 22 Extension Present       | ROS  | 1b      | <b>Clause 22 Extension Present</b><br>0b = Clause 22 extension is not present in the package.<br>1b = Clause 22 extension is present in the package.<br>This is always set to 1b, as the X550 uses this device for the GbE registers. |
| E   | Vendor Specific Device #1 Present | ROS  | 1b      | <b>Vendor Specific Device #1 Present</b><br>0b = Device #1 is not present in the package.<br>1b = Device #1 is present in the package.<br>This is always set to 1b, as the X550 uses this device for the global control registers.    |
| F   | Vendor Specific Device #2 Present | ROS  | 1b      | <b>Vendor Specific Device #2 Present</b><br>0b = Device #2 is not present in the package.<br>1b = Device #2 is present in the package.<br>This is always set to 1b, as the X550 uses this device for the DSP PMA registers.           |

## 10.6.6 Global Standard Status 2: Address 1E.8

| Bit | Name                 | Type | Default | Description                                                                                                                                                                                                                                                |
|-----|----------------------|------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| D:0 | Reserved             | RSV  |         | Reserved. Do not modify.                                                                                                                                                                                                                                   |
| F:E | Device Present [1:0] | ROS  | 10b     | <b>Device Present</b><br>00b = No device at this address.<br>01b = No device at this address.<br>10b = Device present at this address.<br>11b = No device at this address.<br>This field is always set to 10b, as the global MMD resides here in the X550. |

## 10.6.7 Global Standard Package Identifier 1: Address 1E.E

| Bit | Name                   | Type | Default | Description                                              |
|-----|------------------------|------|---------|----------------------------------------------------------|
| F:0 | Package ID MSW [1F:10] | RO   |         | <b>Package ID MSW</b><br>Bits [31:16] of the Package ID. |

## 10.6.8 Global Standard Package Identifier 2: Address 1E.F

| Bit | Name                 | Type | Default | Description                                             |
|-----|----------------------|------|---------|---------------------------------------------------------|
| F:0 | Package ID LSW [F:0] | RO   |         | <b>Package ID LSW</b><br>Bits [15:0] of the Package ID. |

## 10.6.9 Global Firmware ID: Address 1E.20

| Bit | Name                                 | Type | Default | Description                                                                                                                                                        |
|-----|--------------------------------------|------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0 | Firmware Minor Revision Number [7:0] | RO   |         | <b>Firmware Minor Revision Number</b><br>The lower six bits of major and minor firmware revision are exchanged in auto-negotiation when the PHYID message is sent. |
| F:8 | Firmware Major Revision Number [7:0] | RO   |         | <b>Firmware Major Revision Number</b><br>The lower six bits of major and minor firmware revision are exchanged in auto-negotiation when the PHYID message is sent. |

## 10.6.10 Global Diagnostic Provisioning: Address 1E.C400

| Bit | Name               | Type  | Default | Description                                                                  |
|-----|--------------------|-------|---------|------------------------------------------------------------------------------|
| E:0 | Reserved           | RSV   |         | Reserved. Do not modify.                                                     |
| F   | Enable Diagnostics | RW PD | 0b      | <b>Enable Diagnostics</b><br>1b = The X550 performs diagnostics on power up. |

## 10.6.11 Global Thermal Provisioning 2: Address 1E.C421

| Bit | Name                              | Type     | Default             | Description                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----|-----------------------------------|----------|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| F:0 | High Temp Failure Threshold [F:0] | RW<br>PD | 0x4600 <sup>1</sup> | <b>High Temp Failure Threshold</b><br>[F:0] of high temperature failure threshold.<br>2's complement value with the LSB representing 1/256 °C. This corresponds to -40 °C = 0xD800. Default is 70 °C.<br><b>Note:</b> All Thresholds are orthogonal and can be set to any value regardless the value of the other thresholds. IN other words, High Temperature Warning (1E.C423) could be higher than High Temperature Failure (1E.C421). |

1. The default value is overridden to 0x6600 by the provisioning mechanism (see [Section 6.4.9.6](#)).

## 10.6.12 Global Thermal Provisioning 3: Address 1E.C422

| Bit | Name                             | Type     | Default | Description                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----|----------------------------------|----------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| F:0 | Low Temp Failure Threshold [F:0] | RW<br>PD | 0x0     | <b>Low Temp Failure Threshold</b><br>[F:0] of low temperature failure threshold.<br>2's complement value with the LSB representing 1/256 °C. This corresponds to -40 °C = 0xD800. Default is 0 °C.<br><b>Note:</b> All Thresholds are orthogonal and can be set to any value regardless the value of the other thresholds. In other words, High Temperature Warning (1E.C423) could be higher than High Temperature Failure (1E.C421). |

## 10.6.13 Global Thermal Provisioning 4: Address 1E.C423

| Bit | Name                              | Type     | Default             | Description                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----|-----------------------------------|----------|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| F:0 | High Temp Warning Threshold [F:0] | RW<br>PD | 0x3C00 <sup>1</sup> | <b>High Temp Warning Threshold</b><br>[F:0] of high temperature warning threshold.<br>2's complement value with the LSB representing 1/256 °C. This corresponds to -40 °C = 0xD008. Default is 60 °C.<br><b>Note:</b> All Thresholds are orthogonal and can be set to any value regardless the value of the other thresholds. In other words, High Temperature Warning (1E.C423) could be higher than High Temperature Failure (1E.C421). |

1. The default value is overridden to 0x6600 by the provisioning mechanism (see [Section 6.4.9.6](#)).

## 10.6.14 Global Thermal Provisioning 5: Address 1E.C424

| Bit | Name                             | Type     | Default | Description                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----|----------------------------------|----------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| F:0 | Low Temp Warning Threshold [F:0] | RW<br>PD | 0x0A00  | <b>Low Temp Warning Threshold</b><br>[F:0] of low temperature Warning threshold<br>2's complement value with the LSB representing 1/256 °C. This corresponds to -40 °C = 0xD800. Default is 10 °C.<br><b>Note:</b> All Thresholds are orthogonal and can be set to any value regardless the value of the other thresholds. In other words, High-Temperature-Warning (1E.C423) could be higher than High-Temperature-Failure (1E.C421). |

## 10.6.15 Global Reserved Provisioning 1: Address 1E.C470

| Bit | Name                                  | Type     | Default | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| E:D | Extended MDI Diagnostics Select [1:0] | RW<br>PD | 00b     | <b>Extended MDI Diagnostics Select / Diagnostics Select</b><br>These bits select what sort of cable diagnostics to perform. For regular cable diagnostics, Bit [F] is set to 0b, and the diagnostics are triggered by setting Bit [4]. For extended diagnostics, Bit [F] is set to 1b, and the desired extended diagnostics are selected by Bits [E:D]. The routine is then triggered by setting Bit [4]. Each of the extended diagnostic routines present data for all for MDI pairs (A, B, C, D) consecutively, and after the data for each channel is gathered Bits [F:D] are reset. To get the data for the next pair, Bits [F:D] must be set back to the desired value, which must be the same as the initial channel. This continues until the data for all channels has been gathered. The address in memory where the data is stored is given in 1E.C802 and 1E.C804.<br>For PSD, the structure is as follows: <ul style="list-style-type: none"><li>Int32 info</li><li>Int16 data[Len]</li><li>Info = Len &lt;&lt; 16   TxEnable &lt;&lt; 8   Pair (0 = A, etc.)</li></ul> For TDR: <ul style="list-style-type: none"><li>Int32 info</li><li>Int16 tdr_A[Len]</li><li>Int16 tdr_B[Len]</li><li>Int16 tdr_C[Len]</li><li>Int16 tdr_D[Len]</li></ul> Info = Len << 16   Channel<br>TDR data is from the current pair or all other pairs.<br>At the end of retrieving extended MDI diagnostic data, the X550 is reset. Conversely, the only way to exit this routine once it starts is to issue a PMA reset.<br>Bits [E:D] settings: <ul style="list-style-type: none"><li>00b = TDR data.</li><li>01b = RFI channel PSD.</li><li>10b = Noise PSD while the local Tx is off.</li><li>11b = Noise PSD while the local Tx is on.</li></ul> Bit [F] settings: <ul style="list-style-type: none"><li>0b = Provide normal cable diagnostics.</li><li>1b = Provide extended MDI diagnostics information.</li></ul> |

### 10.6.32 Global Fault Message: Address 1E.C850

| Bit | Name          | Type | Default | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----|---------------|------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| F:0 | Message [F:0] | RO   |         | <b>Message</b><br>Error code describing fault.<br>Code Number:<br>0x8001 = Firmware is not compatible with the chip architecture. This fault occurs when firmware is compiled for a different core that is loaded.<br>0x8002 = VCO calibration failed. This occurs when the main PLLs on the chip fail to lock (no trigger is possible).<br>0x8003 = XAUI calibration failed. This occurs when the XAUI PLLs fail to lock (no trigger is possible).<br>0x8005 = Unexpected device ID. This occurs if the device ID programmed into the internal E-Fuse registers is not valid (no trigger is possible).<br>0x8006 = Computed checksum does not match expected checksum. This occurs when the Flash checksum check performed at boot time fails. This only occurs when the system boots from Flash.<br>0x8007 = Detected a bit error in static memory. To trigger, corrupt one of the static regions.<br>0xC001 = Illegal Instruction exception. This occurs when the processor attempts to execute an illegal instruction. To trigger this, write an illegal instruction to program memory. It's possible that the bit error check triggers before the illegal instruction executes.<br>0xC002 = Instruction Fetch Error. Internal physical address or a data error during instruction fetch (no trigger is possible).<br>0xC003 = Load Store Error. Internal physical address or data error during load store operation (no trigger is possible).<br>0xC004 = Privileged Instruction. Attempt to execute a privileged operation without sufficient privilege (no trigger is possible).<br>0xC005 = Unaligned Load or Store. Attempt to load or store data at an address that cannot be handled due to alignment (no trigger is possible).<br>0xC006 = Instruction fetch from prohibited space (no trigger is possible).<br>0xC007 = Data load from prohibited space (no trigger is possible).<br>0xC008 = Data store into prohibited space (no trigger is possible).<br>0xDEAD = Uncorrectable IRAM error.<br>0xDEAE = DRAM parity error.<br>0xDD00 = CRD16 IRAM check failure (IRAM load error).<br>0xFACA = E-Fuse CRC16 check failure (E-Fuse is corrupted). |

### 10.6.33 Global Primary Status: Address 1E.C851

## 11.0 System Manageability

Network management is an important requirement in today's networked computer environment. Software-based management applications provide the ability to administer systems while the operating system is functioning in a normal power state (not in a pre-boot state or powered-down state). The Intel® Out of Band Management fill the management void that exists when the operating system is not running or fully functional. This is accomplished by providing mechanisms by which manageability network traffic can be routed to and from a Management Controller (BMC).

This chapter describes the supported management interfaces and hardware configurations for platform system management. It describes the interfaces to an external BMC, the partitioning of platform manageability among system components, and the functionality provided by the X550 in each platform configuration.

### 11.1 Pass-Through (PT) Functionality

Pass-Through (PT) is the term used when referring to the process of sending and receiving Ethernet traffic over the sideband interface. The X550 has the ability to route Ethernet traffic to the host operating system as well as the ability to send Ethernet traffic over the sideband interface to an external BMC. See [Figure 11-1](#).

**Figure 11-1. Sideband Interface**

The sideband interface provides a mechanism by which the X550 can be shared between the host and the BMC. By providing this sideband interface, the BMC can communicate with the LAN without requiring a dedicated Ethernet controller. The X550 supports three sideband interfaces:

- SMBus
- NC-SI
- PCIe (together with MCTP) - when the system is up.

The usable bandwidth for either direction is up to 1 Mb/s when using SMBus and 100 Mb/s for the NC-SI interface. When working over PCIe, the bandwidth is limited only by the PCIe bandwidth and the the X550 processing capabilities and can sustain any network bandwidth. The X550 should support MCTP over PCIe pass through traffic at a rate of up to 1 Mb/s. Only one mode of sideband can be active at any given time. The configuration is done using an NVM setting.

The maximal packet size supported for traffic received from the LAN to the BMC is 1518 bytes and additional VLAN or E-tag. For traffic from the BMC to the LAN the maximal supported packet size is 1536 bytes including all tags.

**Note:** In MCTP mode, the PCIe and SMBus interface can receive MCTP commands in parallel. For example, the MCTP enumeration process can be done both over SMBus and over PCIe. However, only one of the interfaces can receive NC-SI commands or pass-through traffic.

### 11.1.1 Supported Topologies

The X550 can support some management topologies. The following connections are available:

- Single connection via legacy SMBus (See [Section 11.5](#)).
- Single connection via NC-SI over RMII (See [Section 11.6](#))
- Single connection via NC-SI over MCTP. This connection can be over SMBus, PCI Express or both. This connection can be used either for pass-through or for control only (See [Section 11.7](#)).

The topology used is defined in the *Redirection Sideband Interface* field in the *Common Firmware Parameters* NVM word (see [Section 6.5.2.2](#)) and is common to all the ports in the device.

### 11.1.2 Pass-Through Packet Routing

When an Ethernet packet reaches the X550, it is examined and compared to a number of configurable filters. These filters are configurable by the BMC and include, but not limited to, filtering on:

- MAC Address
- IP Address
- UDP/IP Ports
- VLAN Tags
- EtherType

If the incoming packet matches any of the configured filters, it is passed to the BMC. Otherwise it is not passed.

The packet filtering process is described in [Section 11.3](#).

## 11.2 Components of the Sideband Interface

There are two components to a sideband interface:

- Physical Layer
- Logical Layer

### 11.2.1 Physical Layer

This is the electrical connection between the X550 and BMC.

#### 11.2.1.1 SMBus

The SMBus physical layer is defined by the SMBus specification. The interface is made up of two connections: Data and Clock. There is also an optional third connection: the Alert line. This line is used by the X550 to notify the BMC that there is data available for reading. Refer to the SMBus specification for details.

The SMBus can run at three speeds: 100 KHz (standard SMBus), or 400 KHz (I<sup>2</sup>C fast mode) or 1 MHz (I<sup>2</sup>C fast mode plus). The speed used is selected by the *SMBus Connection Speed* in *SMBus Notification Timeout and Flags* NVM word.

##### 11.2.1.1.1 PEC Support

SMBus transactions can be protected by using Packet Error Code (PEC). Packet Error Checking, whenever applicable, is implemented by appending a PEC byte at the end of each message transfer. The PEC byte is a CRC8 calculation on all the message bytes.

PEC is added in transmit and expected in receive for the following SMBus packets:

- ARP packets.
- MCTP over SMBus transactions.

For ARA cycles and legacy SMBus transactions, a PEC is not expected.

Table 11-1 describes the behavior of the device in each PEC configured mode for transactions directly handled by the hardware upon reception of packets with or without PEC.

**Table 11-1. SMBus PEC Modes<sup>1</sup>**

| SMBus Transaction<br>(Relative to the X550) | X550 PEC Mode | Target PEC Mode                                     |                                                                   |
|---------------------------------------------|---------------|-----------------------------------------------------|-------------------------------------------------------------------|
|                                             |               | PEC Enabled                                         | PEC Disabled                                                      |
| Master Write <sup>2</sup>                   | Enabled       | (A) Target ACKs the PEC byte.                       | (A) Target NACKs the PEC byte.                                    |
|                                             | Disabled      | (A) Target receives stop before expected PEC byte.  | (A) PEC byte is not expected.                                     |
| Slave Write <sup>3</sup>                    | Enabled       | (A) Target ACKs last data byte; PEC byte is NACKed. | (A) Target NACKs last data byte; No PEC byte is written by Slave. |
|                                             | Disabled      | (A) Target ACKs last data byte; PEC byte is 0xFF.   | (A) Target NACKs last data byte and generates Stop after that.    |

Table 11-1. SMBus PEC Modes<sup>1</sup> (Continued)

| SMBus Transaction<br>(Relative to the X550) | X550 PEC Mode | Target PEC Mode                                         |                                                                  |
|---------------------------------------------|---------------|---------------------------------------------------------|------------------------------------------------------------------|
|                                             |               | PEC Enabled                                             | PEC Disabled                                                     |
| Slave Read <sup>4</sup>                     | Enabled       | (A) Target sends PEC byte; PEC byte is ACKed by Slave.  | (A) Target does not send PEC byte and generates Stop after that. |
|                                             | Disabled      | (R) Target sends PEC byte; PEC byte is NACKed by Slave. | (A) Target does not send PEC byte and generates Stop after that. |

1. (A) - Accept Transaction (R) - Reject Transaction
2. Used in Legacy SMBus writes commands (Direct receive) and in MCTP over SMBus (Transmitted transactions).
3. Used in Legacy SMBus Read commands.
4. Used in Legacy SMBus mode (Alert/Async-Notify) and in MCTP over SMBus (Received transactions).

**Note:** In SMBus ARP and MCTP, the specification indicates that PEC must be used. However, if PEC is not used by the master, the transaction is still accepted and processed by the device.

The PEC behavior is controlled by the *SMBus Transaction PEC* bit in the *SMBus Notification Timeout and Flags* NVM word: If this bit is set, PEC is added for master SMBus write transactions. a PEC is added to slave read transactions and can be received in slave write transaction. If this bit is cleared, PEC is not added to master write or slave read transactions, a slave write transaction with PEC is dropped. This bit should be set for MCTP mode and should be cleared in legacy SMBus mode.

### 11.2.1.2 NC-SI

The X550 uses the DMTF standard Sideband Interface. This interface consists of 6 lines for transmission and reception of Ethernet packets and two optional lines for arbitration among more than one physical network controller.

The physical layer of NC-SI is very similar to the RMII interface, although not an exact duplicate. Refer to the NC-SI specification for details of the differences.

### 11.2.1.3 PCIe

The X550 uses the VDMs (Vendor Defined Messages) over PCIe defined in the DMTF MCTP specification to convey pass-through traffic or NC-SI control traffic. See [Section 3.1](#) for details of the PCIe interface.

## 11.2.2 Logical Layer

### 11.2.2.1 Legacy SMBus

The protocol layer for SMBus consists of commands the BMC issues to configure filtering for the X550 management traffic and the reading and writing of Ethernet frames over the SMBus interface. There is no industry standard protocol for sideband traffic over SMBus. The protocol layer for SMBus on the X550 is Intel proprietary. The Legacy SMBus protocol is described in [Section 11.5](#).

### 11.2.2.2 NC-SI

The DMTF also defines the protocol layer for the NC-SI interface. NC-SI compliant devices are required to implement a minimum set of commands. The specification also provides a mechanism for vendors to add additional capabilities through the use of OEM commands. Intel OEM NC-SI commands for the X550 are discussed in [Section 11.6.3](#). For information on base NC-SI commands, see the NC-SI specification.

NC-SI traffic can run on top of three different Physical layers:

1. NC-SI Physical layer as described in [Section 11.2.1.2](#).
2. MCTP over PCIe. This protocol allows control and pass-through traffic over PCIe of a NIC or a LOM device. The NC-SI over MCTP protocol is slightly different than the standard NC-SI as it includes additional NC-SI commands. This mode is usually paired with an MCTP over SMBus, where this mode is used in S0 states and the SMBus interface is used in Sx state. The MCTP protocol and the differences from standard NC-SI is described in [Section 11.7](#).
3. MCTP over SMBus. As described above, this layer is paired with the MCTP over PCIe to support Sx modes.

The X550 exposes one NC-SI package with up to two channels, one per port.

If the number of ports available changes, the package moves to initialization required state and should be re-enumerated. If the transition occurs while one of the ports is in Keep PHY link up state, the transition is delayed until the Keep PHY link up state is cleared.

The X550 implements a type C NC-SI interface (Single package, common bus buffers and shared Rx queue) as described in section 5.2 of the NC-SI specification.

#### 11.2.2.2.1 Package ID Setting

The package ID can be set either from the *Package ID* field in the *NC-SI Configuration 1* NVM word ([Section 6.5.4.5](#)), or from an SDP pin. If set from SDP, the Package ID is {0, SDP0\_0 value, 0}. The mode used is set by the *NC-SI Package ID from SDP* field in the *NC-SI Configuration 2* NVM word ([Section 6.5.4.6](#)). Note that when the package ID is set from the SDP pin, SDP0\_0 should be set as input is *ESDP.SDP0\_IODIR* field.

The internal channel ID matches the lowest numbered PCIe function number through which this port is exposed to the host.

#### 11.2.2.2.2 Channel ID Mapping

The mapping of the channels to physical ports is according to the *NC-SI Channel to Port Mapping* NVM word ([Section 6.5.4.21](#)) if the *Table Valid* bit is set. If this bit is not set, the following algorithm should be used:

```
CHANNEL_ID = 0
If (FACTPS.LAN_FUNCTION_SEL == 0) // no swap
    For (x = 0 to 1) {
        PORT = x;
        If (FACTPS.LANx_VALID) NC-SI_Channel[PORT] = CHANNEL_ID++;
    }
Else // swap
    For (x = 0 to 1) {
        PORT = 1 - x;
        If (FACTPS.LANx_VALID) NC-SI_Channel[PORT] = CHANNEL_ID++;
    }
```

## 11.3 Packet Filtering

Since both the host operating system and BMC use the X550 to send and receive Ethernet traffic, there needs to be a mechanism by which incoming Ethernet packets can be identified as those that should be sent to the BMC rather than the host operating system.

There are two different types of filtering available. The first is filtering based upon the MAC Address. With this filtering, the BMC has at least one dedicated MAC Address and incoming Ethernet traffic with the matching MAC Address(es) are passed to the BMC. This is the simplest filtering mechanism to utilize and it allows an BMC to receive all types traffic (including, but not limited to, IPMI, NFS, HTTP etc).

The other mechanism available utilizes a highly configurable mechanism by which packets can be filtered using a wide range of parameters. Using this method, the BMC can share a MAC Address (and IP Address, if desired) with the host OS and receive only specific Ethernet traffic. This method is useful if the BMC is only interested in specific traffic, such as IPMI packets.

### 11.3.1 Manageability Receive Filtering

This section describes the manageability receive packet filtering flow. Packet reception by the X550 can generate one of the following results:

- Discarded.
- Sent to host memory.
- Sent to the external BMC.
- Sent to both the BMC and host memory.

The decisions regarding forwarding of packets to the host and to the BMC are separate and are configured through two sets of registers. However, the BMC may define some types of traffic as exclusive. This traffic is forwarded only to the BMC, even if it passes the filtering process of the host. These types of traffic are defined using the MNGONLY register ([Section 8.2.2.19.8](#)).

An example of packets that might be necessary to send exclusively to the BMC might be specific TCP/UDP ports of a shared MAC Address or a MAC Address dedicated to the BMC. If the BMC configures the manageability filters to send these ports to the BMC, it should configure the settings to not send them to the host, otherwise, these ports are received and handled by the host operating system.

The BMC controls the types of packets that it receives by programming receive manageability filters. The following filters are accessible to the BMC:

**Table 11-2. Filters Accessible to BMC**

| Filters                              | Functionality                                                | When Reset   |
|--------------------------------------|--------------------------------------------------------------|--------------|
| Filters Enable                       | General configuration of the manageability filters           | LAN_PWR_GOOD |
| Manageability Only                   | Enables routing of packets exclusively to the manageability. | LAN_PWR_GOOD |
| Manageability Decision Filters [7:0] | Configuration of manageability decision filters              | LAN_PWR_GOOD |
| MAC Address [3:0]                    | Four unicast MAC manageability addresses                     | LAN_PWR_GOOD |
| VLAN Filters [7:0]                   | Eight VLAN tag values                                        | LAN_PWR_GOOD |
| UDP/TCP Port Filters [15:0]          | 16 destination port values                                   | LAN_PWR_GOOD |
| Flexible 128 bytes TCO Filter        | Length and values for one flex TCO filter                    | LAN_PWR_GOOD |
| IPv4 and IPv6 Address Filters [3:0]  | IP Address for manageability filtering                       | LAN_PWR_GOOD |

All filtering capabilities are available on both the NC-SI and legacy SMBus interfaces. However, in NC-SI mode, to program part of the capabilities, the Intel OEM commands described in [Section 11.6.3](#) should be used.

All filters are reset only on Internal Power On Reset. Register filters that enable filters or functionality are also reset by firmware reset in NC-SI mode. These registers can be loaded from the NVM following a reset in SMBus mode. See [Section 6.5.2.3](#) for description of their location in the NVM map.

The high-level structure of manageability filtering is done using two steps.

1. The packet is parsed and fields in the header are compared to programmed filters.
2. A set of decision filters are applied to the result of the first step.

Some general rules apply:

- Fragmented packets are passed to manageability but not parsed beyond the IP header.
- Packets with L2 errors (CRC, alignment, etc.) are not forwarded to the BMC.
- Packets longer than 2KB are filtered out.
- The filtering relates only to the outer L3/L4 header. In tunneled packets, the inner L2, L3 and L4 header parameters are not considered for manageability filtering.

The following sections describe the manageability filtering, followed by the final filtering rules.

The filtering rules are created by programming the decision filters as described in [Section 11.3.4](#).

## 11.3.2 L2 Filters

### 11.3.2.1 MAC and VLAN Filters

The manageability MAC filters allow comparison of the Destination MAC Address to one of 4 filters defined in the MMAH and MMAL registers.

The VLAN filters allow comparison of the 12-bit VLAN tag to one of 8 filters defined in the MAVTV registers.

### 11.3.2.2 EtherType Filters

Manageability L2 EtherType filters allow filtering of received packets based on the Layer 2 EtherType field. The L2 type field of incoming packets is compared against the EtherType filters programmed in the Manageability EtherType Filter (METF; up to 4 filters); the result is incorporated into decision filters.

Each Manageability EtherType filter can be configured as pass (positive) or reject (negative) using a polarity bit. For the reverse polarity mode to be effective and block certain type of packets, the EtherType filter should be part of all the enabled decision filters.

An examples for usage of L2 EtherType filters is to determine the destination of 802.1X control packets. The 802.1X protocol is executed at different times in either the management controller or by the Host. L2 EtherType filters are used to route these packets to the proper agent.

In addition to the flexible EtherType filters, the X550 supports 2 fixed EtherType filters used to block NC-SI control traffic (0x88F8) and flow control traffic (0x8808) from reaching the manageability interface. The NC-SI EtherType is used for communication between the management controller on the NC-SI link and the X550. Packets coming from the network are not expected to carry this EtherType and such packets are blocked to prevent attacks on the management controller. Flow control packets

should be consumed by the MAC and as such are not expected to be forwarded to the management interface.

### 11.3.3 L3/L4 Filtering

The manageability filtering stage combines checks done at previous stages with additional L3/L4 checks to make a the decision on whether to route a packet to the BMC. The following sections describe the manageability filtering done at layers L3/L4 and final filtering rules.

**Note:** The L3 filters do not match tunneled fields (L3, L4 or ARP).

#### 11.3.3.1 ARP Filtering

ARP filtering — The X550 supports filtering of ARP request packets (initiated externally) and ARP responses (to requests initiated by the BMC).

In legacy SMBus mode, the ARP filters can be used as part of the ARP offload described in [Section 11.5.4](#). ARP offload is not specifically available when using NC-SI. However, the general filtering mechanism is utilized to filter incoming ARP traffic as requested using the Enable Broadcast Filtering NC-SI command.

To limit the reception of ARP packets to the ARP packets dedicated to this station (ARP target IP = BMC IP), the ARP request/response filter can be bind to specific IP Address, by setting both the ARP Request/Response and the IP AND bits in an MDEF filter, as the *IP* bit is set also if there is a match on the target IP (the TPA field in the ARP packet) of an ARP request or an ARP response.

**Note:** If the OR section of the MDEF is all cleared and one of the IPv4 address are set, ARP packets matching the IP Address pass the filter. If these packets should be dropped, an OR Ethertype filter with a a value of 0x0800 (IPv4) should be added.

#### 11.3.3.2 Neighbor Discovery Filtering and MLD

The X550 supports filtering of the following ICMPv6 packets.

**Neighbor Discovery packets:**

- 0x86 (134d) - Router Advertisement.
- 0x87 (135d) - Neighbor Solicitation.
- 0x88 (136d) - Neighbor Advertisement.
- 0x89 (137d) - Redirect.

**MLD packets:**

- 0x82 (130d) - MLD Query
- 0x83 (131d) - MLDv1 Report
- 0x84 (132d) - MLD Done
- 0x8F (143d) - MLDv2 Report

The Neighbor Discovery packets has dedicated enables for each type in the decision filters. For MLD, a single enable controls the forwarding of all the MLD packets. This means that either all the MLD packets types are selected for reception or none of them.

### 11.3.3.3 RMCP Filtering

The X550 supports filtering by fixed destination port numbers, port 0x26F and port 0x298. These ports are IANA reserved for RMCP.

In SMBus mode, there are filters that can be enabled for these ports. When using NC-SI, they are not specifically available. However, the general filtering mechanism can be utilized to filter incoming ARP traffic.

### 11.3.3.4 Flexible Port Filtering

The X550 implements 16 flex destination port filters. The X550 directs packets whose L4 destination port matches to the BMC. The BMC must ensure that only valid entries are enabled in the decision filters.

### 11.3.3.5 IP Address Filtering

The X550 supports filtering by destination IP Address using IPv4 and IPv6 address filters. These are dedicated to manageability. The X550 provides four IPv6 address filters or three IPv6 addresses and four IPv4 address filters.

The IPv4 match rises also for ARP packets for which the Target IP matches the IP Address in the MIPAF4 register.

### 11.3.3.6 Checksum Filtering

If bit `MANC.EN_XSUM_FILTER` is set, the X550 directs packets to the BMC only if they match all other filters previously described as well as pass L3/L4 checksum (if it exists).

The X550 may be instructed to direct packets to the BMC only if they pass L3/L4 checksum (if they exist) in addition to matching other filters previously described.

Enabling the XSUM filter when using the SMBus interface is accomplished by setting the *Enable XSUM Filtering to Manageability* bit (`MANC.EN_XSUM_FILTER`). This is done using the Update Management Receive Filter Parameters command (see [Section 11.5.11.1.6](#)), or using Set Common Filters Receive Control Bytes (data 2:4, command 0xC2) (see [Section 11.5.11.1.7](#)).

To enable the XSUM filtering when using NC-SI, use the Enable Checksum Offloading command (see [Section 11.6.3.15](#)).

### 11.3.4 Flexible 128 Byte Filter

The X550 provides one flex TCO filter. This filter looks for a pattern match within the first 128 bytes of the packet.

Flex filters are temporarily disabled when read from or written to by the host. Any packet received during a read or write operation is dropped. Filter operation resumes once the read or write access completes.

#### 11.3.4.1 Flexible Filter Structure

The filter is composed of the following fields:

- **Flexible Filter Length** — This field indicates the number of bytes in the packet header that should be inspected. The field also indicates the minimal length of packets inspected by the filter. Packet below that length are not inspected. Valid values for this field are:  $8*n$ , where  $n=1...16$ .
- **Data** — This is a set of up to 128 bytes comprised of values that header bytes of packets are tested against.
- **Mask** — This is a set of 128 bits corresponding to the 128 data bytes that indicate for each corresponding byte if is tested against its corresponding byte. The general filter is 128 bytes that the BMC configures; all of these bytes may not be needed or used for the filtering, so the mask is used to indicate which of the 128 bytes are used for the filter.

Each filter tests the first 128 bytes (or less) of a packet, where not all bytes must necessarily be tested.

#### 11.3.4.2 TCO Filter Programming

Programming each filter is done using the following commands (NC-SI or SMBus) in a sequential manner:

1. **Filter Mask and Length** — This command configures the following fields:
  - a. **Mask** — A set of 16 bytes containing the 128 bits of the mask. Bit 0 of the first byte corresponds to the first byte on the wire.
  - b. **Length** — A 1-byte field indicating the length.
2. **Filter Data** — The filter data is divided into groups of bytes. as described below:

| Group | Test Bytes |
|-------|------------|
| 0x0   | 0-29       |
| 0x1   | 30-59      |
| 0x2   | 60-89      |
| 0x3   | 90-119     |
| 0x4   | 120-127    |

Each group of bytes need to be configured using a separate command, where the group number is given as a parameter. The command has the following parameters:

- **Group number** — A 1-byte field indicating the current group addressed.
- **Data bytes** — Up to 30 bytes of test-bytes for the current group.

## 11.3.5 Configuring Manageability Filters

There are a number of pre-defined filters that are available for the BMC to enable, such as ARPs and IPMI ports 298h 26Fh. These are generally enabled by setting the appropriate bit within the MANC register using specific commands.

For more advanced filtering needs, the BMC has the ability to configure a number of configurable filters. It is a two-step process to use these filters. They must first be configured and then enabled.

### 11.3.5.1 Manageability Decision Filters

Manageability decision filters (MDEF) are a set of eight filters, each with the same structure. The filtering rule for each decision filter is programmed by the BMC and defines which of the L2, VLAN, Ethertype and L2/L3 filters participate in decision making. Any packet that passes at least one rule is directed to manageability and possibly to the host.

The inputs to each decision filter are:

- Packet passed a valid management L2 exact address filter.
- Packet is a broadcast packet.
- Packet has a VLAN header and it passed a valid manageability VLAN filter.
- Packet matched one of the valid IPv4 or IPv6 manageability address filters.
- Packet is a multicast packet.
- Packet passed ARP filtering (request or response).
- Packet passed neighbor solicitation filtering.
- Packet passed MLD filtering.
- Packet passed 0x298/0x26F port filter.
- Packet passed a valid flex port filter.
- Packet passed a valid flex TCO filter.
- Packet passed or failed an L2 EtherType filter.
- Packet passed or failed Flow Control or NC-SI L2 EtherType Discard filter.

The structure of each decision filter is shown in [Figure 11-2](#). A boxed number indicates that the input is conditioned by a mask bit defined in the MDEF register and MDEF\_EXT register for this rule. Decision filter rules are as follows:

- At least one bit must be set in a register. If all bits are cleared (MDEF/MDEF\_EXT = 0x0000), the decision filter is disabled and ignored.
- All enabled AND filters must match for the decision filter to match. An AND filter not enabled in the MDEF/MDEF\_EXT registers is ignored. If an AND filter is preceded by a OR filter, at least one of the enabled OR inputs must match for the filter to pass.
- If no OR filter is enabled in the register, the OR filters are ignored in the decision (the filter might still match).
- If one or more OR filters are enabled in the register, at least one of the enabled OR filters must match for the decision filter to match.

**Figure 11-2. Manageability Decision Filters**

A decision filter (for any of the 8 filters) defines which of the above inputs is enabled as part of a filtering rule. The BMC programs two 32-bit registers per rule (MDEF[7:0] & MDEF\_EXT[7:0]) with the settings as described in [Section 8.2.2.19.9](#) and [Section 8.2.2.19.5](#). A set bit enables its corresponding filter to participate in the filtering decision.

In addition to the controls described above, the MDEF\_EXT.APPLY\_TO\_HOST\_TRAFFIC and MDEF\_EXT.APPLY\_TO\_NETWORK\_TRAFFIC bits defines which traffic is compared to this filter. At least one of these bits must be set for the filter to be valid.

If the MDEF\_EXT.APPLY\_TO\_HOST\_TRAFFIC bit is set, the traffic from the host is candidate for this filter. If the MDEF\_EXT.APPLY\_TO\_NETWORK\_TRAFFIC bit is set, the traffic from the network is candidate for this filter. If both bits are set, this filter is applied to all traffic.

### 11.3.5.2 Exclusive Traffic

The decisions regarding forwarding of packets to the host for LAN traffic or to the LAN for host traffic are independent from the management decision filters. However, the BMC may define some types of traffic as exclusive. The behavior for such traffic is defined by the using the bits corresponding to the decision filter in the MNGONLY register (one bit per each of the eight decision rules) and the MDEF\_EXT.APPLY\_TO\_HOST\_TRAFFIC and MDEF\_EXT.APPLY\_TO\_NETWORK\_TRAFFIC bits.

Table 11-3 describes the behavior in each case. If one or more filters match the traffic and at least one of the filters is set as exclusive, the traffic is treated as exclusive.

**Table 11-3. Exclusive Traffic Behavior**

| Traffic Source | Filter Matches                                                                                             |                                             | Filter Does Not Match                                        |
|----------------|------------------------------------------------------------------------------------------------------------|---------------------------------------------|--------------------------------------------------------------|
|                | MNGONLY = 0                                                                                                | MNGONLY = 1                                 | N/A                                                          |
| From network   | Traffic is forwarded to the manageability.<br>Traffic is forwarded to the host according to host filtering | Traffic is forwarded only to manageability. | Traffic is forwarded to the host according to host filtering |
| From host      | Traffic is forwarded to the manageability and to the LAN                                                   | Traffic is forwarded only to manageability. | Traffic is forwarded to the LAN                              |

Any traffic matching any of the configurable filters (see Section 11.3.5.1) can be used as filters to pass traffic to the host.

**Table 11-4. MNGONLY Register Description and Usage**

| Bits | Description       | Default                                                                                                                                                                                                                           |
|------|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0    | Decision Filter 0 | Determines if packets that have passed decision filter 0 are sent exclusively to the manageability path.                                                                                                                          |
| 1    | Decision Filter 1 | Determines if packets that have passed decision filter 1 are sent exclusively to the manageability path.                                                                                                                          |
| 2    | Decision Filter 2 | Determines if packets that have passed decision filter 2 are sent exclusively to the manageability path.                                                                                                                          |
| 3    | Decision Filter 3 | Determines if packets that have passed decision filter 3 are sent exclusively to the manageability path.                                                                                                                          |
| 4    | Decision Filter 4 | Determines if packets that have passed decision filter 4 are sent exclusively to the manageability path.                                                                                                                          |
| 5    | Unicast and Mixed | NC-SI mode:<br>Determines if unicast and mixed packets are sent exclusively to the manageability path.<br>SMBus mode:<br>Determines if packets that have passed decision filter 5 are sent exclusively to the manageability path. |
| 6    | Global Multicast  | NC-SI mode:<br>Determines if multicast packets are sent exclusively to the manageability path.<br>SMBus mode:<br>Determines if packets that have passed decision filter 6 are sent exclusively to the manageability path.         |
| 7    | Broadcast         | NC-SI mode:<br>Determines if broadcast packets are sent exclusively to the manageability path.<br>SMBus mode:<br>Determines if ARP packets are sent exclusively to the manageability path.                                        |
| 31:8 | Reserved          | Reserved.                                                                                                                                                                                                                         |

When using the SMBus interface, the BMC enables these filters by issuing the Update Management Receive Filter Parameters command (see Section 11.5.11.1.6) with the parameter of 0x0F.

The MNGONLY register is also configurable when using NC-SI using the Set Intel Filters — Manageability Only Command (see Section 11.6.3.7.2).

All manageability filters are controlled by the BMC only and not by the LAN device driver.

### 11.3.5.3 Global Controls

On top of the MDEF filters, the MANC register contains some global controls applied to all the packets to be candidate for manageability filtering:

- Receive Enable bits:
  - The *RCV\_TCO\_EN* field controls the reception of manageability traffic. It should be set only if one of the following bits is set also.
  - The *EN\_BMC2OS* bit controls the reception of manageability traffic from the host.
  - The *EN\_BMC2NET* bit controls the reception of manageability traffic from the network.

- VLAN filtering:

To support the NC-SI VLAN modes the following controls are provided:

- The *FIXED\_NET\_TYPE* field controls if only VLAN tagged or VLAN un-tagged traffic is received. If this bit is cleared both types are received. If it is set, only the type described by the *NET\_TYPE* field is accepted.
- If set, the *NET\_TYPE* field indicates that only VLAN tagged traffic is received, if cleared only packets without VLAN is accepted. This field is validated by the *FIXED\_NET\_TYPE* field.

Both fields relates to the inner VLAN.

### 11.3.6 Filtering Programming Interfaces

The X550 provides multiple options to program the forwarding filters, depending on the interface used and the level of flexibility needed. [Table 11-5](#) describes the different options and points to the description of the relevant commands.

**Table 11-5. Filtering Programming Interfaces**

| Interface                      | Flexible/Abstract                | Description                                                                                                                                                                                                                                                                                       |
|--------------------------------|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NC-SI (over RMII or over MCTP) | Abstract (dedicated MAC Address) | The regular NC-SI commands can be used to allow forwarding based on a dedicated MAC Address. The list of supported commands can be found in <a href="#">Section 11.6.2.1</a> . When using these commands, one of the two other modes can be used to add finer grain filtering.                    |
|                                | Flexible                         | This interface described in most of the subsections of <a href="#">Section 11.6.3.4</a> . It uses the packet reduction commands to reduce the forwarding scope of the filters set by the regular NC-SI commands and the packet addition commands to add new packet types to the forwarding rules. |
| SMBus                          | Abstract                         | The Set Common filter command ( <a href="#">Section 11.5.11.1.7</a> ) can be used to set the most common filters. When using this commands the flexible filtering interface should not be used. When sending this command, all previous filtering requests are cleared.                           |
|                                | Flexible                         | The Update MNG RCV Filter Parameters ( <a href="#">Section 11.5.11.1.6</a> ) can be used to define the exact filtering rules to be applied.                                                                                                                                                       |

## 11.3.7 Possible Configurations

This section describes ways of using management filters. Actual usage may vary.

### 11.3.7.1 Dedicated MAC Packet Filtering

- Select one of the eight rules for dedicated MAC filtering.
- Load Host MAC Address to one of the management MAC Address filters and set the appropriate bit in field 3:0 of the MDEF register.
- Set other bits to qualify which packets are allowed to pass through. For example:
  - Set bit 5 in MDEF to qualify with the first manageability VLAN.
  - Set relevant bits 13 to 20 in MDEF to qualify with a match to one of the IP Addresses.
  - Set any L3/L4 bits (bits 27 to 31 in MDEF and bits 16 to 23 in MDEF\_EXT) to qualify with any of a set of L3/L4 filters.

### 11.3.7.2 Broadcast Packet Filtering

- Select one of the eight rules for broadcast filtering.
- Set bit 25 in MDEF of the decision rule to enforce broadcast filtering.
- Set other bits to qualify which broadcast packets are allowed to pass through. For example:
  - Set bit 5 in MDEF to qualify with the first manageability VLAN.
  - Set relevant bits 13 to 20 in MDEF to qualify with a match to one of the IP Addresses.
  - Set any L3/L4 bits (bits 27 to 31 in MDEF, and bits 16 to 23 in MDEF\_EXT) to qualify with any of a set of L3/L4 filters.

### 11.3.7.3 VLAN Packet Filtering

- Select one of the eight rules for VLAN filtering.
- Set bit 5 to 12 in MDEF to qualify with the relevant manageability VLANs.
- Set other bits to qualify which VLAN packets are allowed to pass through. For example:
  - Set any L3/L4 bits (bits 27 to 31 in MDEF, and bits 16 to 23 in MDEF\_EXT) to qualify with any of a set of L3/L4 filters.

#### 11.3.7.4 IPv6 Filtering

IPv6 filtering is done using the following IPv6-specific filters:

- IP Unicast filtering — requires filtering for Link Local address and a Global address. Filtering setup might depend on whether the MAC Address is shared with the host or dedicated to manageability:
  - Dedicated MAC Address (for example, dynamic address allocation with DHCP does not support multiple IP Addresses for one MAC Address). In this case, filtering can be done at L2 using two dedicated unicast MAC filters.
  - Shared MAC Address (for example, static address allocation sharing addresses with host). In this case, filtering needs to be done at L3, requiring two IPv6 address filters, one per address.
- A neighbor Discovery filter — The X550 supports IPv6 neighbor Discovery protocol. Since the protocol relies on multicast packets, the X550 supports filtering of these packets. IPv6 multicast addresses are translated into corresponding Ethernet multicast addresses in the form of 33-33-xx-xx-xx-xx, where the last 32 bits of address are taken from the last 32 bits of the IPv6 multicast address. As a result, two direct MAC filters can be used to filter IPv6 solicited-node multicast packets as well as IPv6 all node multicast packets.

#### 11.3.7.5 Receive Filtering with Shared IP

When using the Legacy SMBus interface, it is possible to share the host MAC and IP Address with the BMC. This functionality is also available when using base NC-SI using Intel OEM commands.

When the BMC shares the MAC and IP Address with the host, receive filtering is based on identifying specific flows through port allocation. The following setting might be used when using the legacy SMBus interface:

- Select one of the eight rules.
- Set a manageability dedicated MAC filter to the host MAC Address and set the matching bit (0-3) in the MDEF register.
- If VLAN is used for management, load one or more management VLAN filters and set the matching bit (5-12) in the MDEF register.

ARP filter/neighbor Discovery filter is enabled when the BMC is responsible for handling the ARP protocol. Set bit 27 or bit 28 in the MDEF register for this functionality.

### 11.3.8 Determining Manageability MAC Address

If the BMC wishes to use a dedicated MAC Address or configure the automatic ARP response mechanism (only available in SMBus mode), it may be beneficial for the BMC to be able to determine the MAC Address used by the host.

Both the NC-SI and SMBus interfaces provide an Intel OEM command to read the System MAC Address.

A possible use for this is that the MAC Address programmed at manufacturing time does not increment by one each time, but rather by two. In this way, the BMC can read the System MAC Address and add one to it and be guaranteed of a unique MAC Address.

Determining the IP Address being used by the host is beyond the scope of this document.

## 11.4 OS-to-BMC Traffic

### 11.4.1 Overview

Traditionally, the communication between a host and the local BMC is not handled through the network interface and requires a dedicated interface such as an IPMI KCS interface. The X550 allows the host and the local BMC communication via the regular pass-through interface, and thus allow management of a local console using the same interface used to manage any BMC in the network.

When this flow is used, the host sends packets to the BMC through the network interface. The X550 examines these packets and then decides if they should be forwarded to the BMC. On the inverse path, when the BMC sends a packet on the pass-through interface, the X550 checks if it should be forwarded to the network, the host, or both. [Figure 11-3](#) describes the flow for OS-to-BMC traffic for the NC-SI over RMII case. OS2BMC is available also when working over MCTP. It is not supported in legacy SMBus mode.

The OS-to-BMC flow can be enabled using the *OS2BMC enable* field for the relevant port in the *OS 2 BMC configuration* structure of the NVM.

**Figure 11-3. OS-to-BMC Diagram**

The OS-to-BMC flow is enabled only for ports enabled by the NC-SI “Enable Channel” command or via the *OS-to-BMC Enable* field for the relevant port in the OS-to-BMC configuration structure of the NVM. When the MC uses IPsec for the flow directed to the host, it should make sure the X550 does not offload the IPsec flow by exposing the IP Address used via the *Set IP Address* NC-SI OEM command.

OS2BMC traffic must comply with NC-SI specifications and is therefore limited to maximum sized frames of 1536 bytes (in both directions).

## 11.4.2 Filtering

When OS-to-BMC traffic is enabled, the filters used for network to BMC traffic are also used for OS-to-BMC traffic. Traffic considered as exclusive to the BMC (Relevant bit in MNGONLY is set) is also considered as exclusive to the BMC when sent from the Host and not forwarded to the network.

### 11.4.2.1 Handling of OS-to-BMC Packets

All the regular transmit offloads are also available for OS-to-BMC packets.

### 11.4.2.2 BMC-to-OS Filtering

When OS-to-BMC is enabled, as with regular BMC transmit traffic, the port (OS or network) to which the packet is sent is fixed according to the source MAC Address of the packet. After that, the BMC traffic is filtered according to the L2 Host filters of the selected port (as described in [Section 7.1.2](#)). According to the results of the filtering the packet can be forwarded to the OS, the network or both.

The following rules apply to the forwarding of OS packets:

- If *BMC to net* is disabled, all the traffic from the BMC is sent to the Host.
- If *BMC to host* is disabled, all the traffic from the BMC is sent to the network.
- If both *BMC to net* and *BMC to host* are enabled, the packet is forwarded only according to the destination MAC Address and VLAN tag. Unicast packets that matches one of the exact filters (RAH/RAL) are sent only to the Host. Other packets that pass the L2 Host filtering are sent to both the Host and the network. Packets that do not pass the L2 host filtering are sent only to the network.

**Note:** In virtualization mode, if packet is received by host only due to default pooling (PFVTCTL.DIS\_DEF\_POOL bit is cleared), it is not sent to the host (even if *BMC to net* is disabled).

### 11.4.2.3 Queuing of Packets Received from the BMC

Packets received from the BMC are queued in the default queue.

#### 11.4.2.4 Offloads of Packets Received from the BMC

Packets received from the BMC and forwarded to the OS do not pass the same path as regular network packets. Thus parts of the offloads provided for the network packets are not available for the BMC packets. Packet received from the BMC are identified by the *RDESC.STATUS.BMC* bit.

The following list describes which offloads are available for BMC packets:

- CRC is checked and removed on the BMC packets.
- The BMC packets are not detected as time sync packet. The *RDESC.STATUS.TS* is always clear for these packets.
- In systems where the double VLAN feature is enabled (*CTRL\_EXT.EXTENDED\_VLAN* is set), the *VEXT* bit is valid for BMC packets and reflects the presence of a tag with an Ethertype matching the value in *EXVET* register.

**Note:** In systems that uses double VLAN, the BMC is expected to send all packets (apart from NC-SI commands) with the outer VLAN included. Failing to do so may cause corruptions to the packet received by the OS

- The *RDESC.ERRORS* field is always cleared for these packets.

**Note:** Traffic sent from the BMC does not cause a PME event, even if it matches one of the wake-up filters set by the port.

#### 11.4.3 Blocking of Network to BMC Flow

In some systems the BMC may have its own private connection to the network and may use the X550 port only for the OS-to-BMC traffic. In this case, the BMC to network flow should be blocked while enabling the OS-to-BMC and OS to network flows.

This can be done by clearing the *MANC.EN\_BMC2NET* bit for the relevant port. The BMC can control this functionality using the "Enable Network to BMC flow" and "Disable Network to BMC flow" NC-SI OEM commands. This can also be controlled using the *Network to BMC disable* field in the NVM "OS2BMC Configuration Structure".

**Notes:** When network to BMC flow is blocked and OS-to-BMC flow is enabled, all the traffic from the BMC is sent to the OS without any check. The OS traffic filtering is still done using the regular decision filters.

The NC-SI channel should not be enabled for receive or transmit before at least one of the *EN\_BMC2NET* or *EN\_BMC2OS* fields is set, unless used for AEN transmissions only. In this case, the channel may be enabled for receive, but all receive filters should be cleared.

#### 11.4.4 OS2BMC and Flow Control

The traffic between the host and manageability uses the same buffers as any loopback traffic. Thus it flows through the transmit buffer and then through the receive buffer. If the transmit buffer is flow controlled, the host to BMC traffic is also stopped. If the receive buffer is full, the traffic is dropped or the transmit is stopped according to the flow control policy of this traffic class.

Packets received to the manageability (either from host or from network) may be dropped if the manageability internal buffers are full.

## 11.4.5 Statistics

Packets sent from the OS to the BMC should be counted by all statistical counters as packets sent by the OS. If they are sent to both the network and to the BMC, they are counted once.

Packets sent from the BMC to the host are counted as packets received by the host. If they are sent to the host and to the network, they are counted both as received packets and as packet transmitted to the network.

In addition, the X550 supports the following statistical counters that measure just the BMC-to-OS and OS-to-BMC traffic:

- O2BGPTC: OS-to-BMC packets received by BMC
- O2BSPC: OS-to-BMC packets transmitted by OS and received by manageability buffer.
- B2OSPC: BMC-to-OS packets sent by BMC
- B2OGPRC: BMC-to-OS packets received by OS.

The driver can use these statistics to count packets dropped by the X550 during the transfer between the OS and the BMC or the LAN and the BMC as follows:

- Dropped packets in BMC-to-OS path =  $B2OSPC - B2OGPRC$
- Dropped packet in BMC to LAN path =  $B2OSDPC - (B2OSPC - B2OGPRC)$
- Dropped packets in OS-to-BMC path =  $O2BSPC - O2BGPTC$
- Dropped packets in LAN to BMC path =  $MNGPDC$

See [Section 7.1.7.2](#) and [Section 7.1.5.2](#) for details of the statistics hierarchy.

## 11.4.6 OS-to-BMC Enablement

The X550 supports the unified network software model for OS-to-BMC traffic, where the OS-to-BMC traffic is shared with the regular traffic. In this model, there is no need for a special configuration of the OS networking stack or the BMC stack. However, if the link is down, the OS-to-BMC communication is stopped.

To enable OS-to-BMC, either:

- Enable OS2BMC in the *Port Traffic Type* field in the *Traffic Type Parameters* NVM word for the relevant port.
- Send an Enable Network to BMC Command

**Note:** When OS2BMC is enabled, OS must avoid sending packets longer than 1.5 KB to BMC.

## 11.5 SMBus Pass-Through Interface

SMBus is the system management bus defined by Intel. It is used in personal computers and servers for low-speed system management communications. This section describes how the SMBus interface operates in legacy pass-through mode.

### 11.5.1 General

The SMBus sideband interface includes standard SMBus commands used for assigning a slave address and gathering device information as well as Intel proprietary commands used specifically for the pass-through interface.

### 11.5.2 Pass-Through Capabilities

This section details manageability capabilities the X550 provides while in SMBus mode. Pass-through traffic is carried by the sideband interface as described in [Section 11.1](#).

These services are not available in NC-SI mode.

When operating in SMBus mode, in addition to exposing a communication channel to the LAN for the BMC, the X550 provides the following manageability services to the BMC:

- **ARP handling** — The X550 can be programmed to auto-ARP replying for ARP request packets to reduce the traffic over the BMC interconnect.
- **Default configuration of filters by NVM** — When working in SMBus mode, the default values of the manageability receive filters can be set according to the PT LAN and flex TCO NVM structures.

### 11.5.3 Port to SMBus Mapping

The X550 is presented on the SMBus manageability link as two different devices (for example, via two different SMBus addresses on which each device is connected to a different LAN port). There is no logical connection between the devices.

The fail-over between the LAN ports is done by the BMC (by sending/receiving packets through different devices). The status report to the BMC, ARP handling, DHCP, and other pass-through functionality are unique for each port and configured by the BMC.

If the number of enable ports changes, the port enable state is updated, and an alarm is set according to the programmed notification method. Bit 6 in Status data byte 2 of all the currently-enabled functions is set to indicate the change. The BMC can then detect the change in the configuration and do a new ARP flow or try to discover if new ports were added or removed.

## 11.5.4 Automatic Ethernet ARP Operation

The X550 can offload the Ethernet Address Resolution Protocol (ARP) for the BMC to reduce the bandwidth required on the SMBus link.

Automatic Ethernet ARP parameters are loaded from the NVM when the X550 is powered up or configured through the sideband management interface. The following parameters should be configured to enable ARP operation:

- ARP auto-reply enabled.
- ARP IP Address (to filter ARP packets).
- ARP MAC Addresses (for ARP responses).

These are all configurable over the sideband interface using the advanced version of the Receive Enable command.

When an ARP request packet is received and ARP auto-reply is enabled, the X550 checks the targeted IP Address (after the packet has passed L2 checks and ARP checks). If the targeted IP matches the IP configuration for the X550, it replies with an ARP response.

The X550 responds to ARP request targeted to the ARP IP Address with the configured ARP MAC Address. In case that there is no match, the X550 silently discards the packets. If the X550 is not configured to do auto-ARP response, it can be configured to forward the ARP packets to the BMC (which can respond to ARP requests).

When the external BMC uses the same IP and MAC Address of the OS, the ARP operation should be coordinated with the host operating system.

**Note:** If sharing the MAC and IP with the host operating system is possible, the X550 provides the ability to read the stem MAC Address, allowing the BMC to share the MAC Address. There is no mechanism however provided by the X550 to read the IP Address. The host OS (or an agent within) and BMC must coordinate the sharing of IP Addresses.

## 11.5.5 SMBus Transactions

This section gives a brief overview of the SMBus protocol. Following is an example for a format of a typical SMBus transaction.

**Table 11-6. Typical SMBus Transaction**

|          |                      |           |          |                |          |                  |          |          |
|----------|----------------------|-----------|----------|----------------|----------|------------------|----------|----------|
| <b>1</b> | <b>7</b>             | <b>1</b>  | <b>1</b> | <b>8</b>       | <b>1</b> | <b>8</b>         | <b>1</b> | <b>1</b> |
| <b>S</b> | <b>Slave Address</b> | <b>Wr</b> | <b>A</b> | <b>Command</b> | <b>A</b> | <b>PEC</b>       | <b>A</b> | <b>P</b> |
|          | 1100 001             | 0         | 0        | 0000 0010      | 0        | [Data Dependent] | 0        |          |

The top row of the table identifies the bit length of the field in a decimal bit count. The middle row (bordered) identifies the name of the fields used in the transaction. The last row appears only with some transactions, and lists the value expected for the corresponding field. This value can be either hexadecimal or binary.

The SMBus controller is a master for some transactions and a slave for others. The differences are identified in this document.

Shorthand field names are listed in [Table 11-7](#) and are fully defined in the SMBus specification.

**Table 11-7. Shorthand Field Names**

| Field Name | Definition                         |
|------------|------------------------------------|
| S          | SMBus START Symbol                 |
| P          | SMBus STOP Symbol                  |
| PEC        | Packet Error Code                  |
| A          | ACK (Acknowledge)                  |
| N          | NACK (Not Acknowledge)             |
| Rd         | Read Operation (Read Value = 1b)   |
| Wr         | Write Operation (Write Value = 0b) |

### 11.5.5.1 SMBus Addressing

The SMBus is presented as up to two SMBus devices on the SMBus (two addresses). All pass-through functionality is duplicated on the SMBus address, where each SMBus address is connected to a different LAN port. Note that it is not permitted to configure multiple ports to the same SMBus address. When a LAN function is disabled, the corresponding SMBus address is not presented to the BMC.

SMBus addresses (enabled from the NVM) can be re-assigned using the SMBus ARP protocol.

In addition to the SMBus address values, all parameters of the SMBus (SMBus channel selection, address mode, and address enable) can be set only through NVM configuration. Note that the NVM is read at the X550's power up and resets.

### 11.5.5.2 SMBus ARP Functionality

The X550 supports the SMBus ARP protocol as defined in the SMBus 2.0 specification. The X550 is a persistent slave address device so its SMBus address is valid after power-up and loaded from the NVM. The X550 supports all SMBus ARP commands defined in the SMBus specification both general and directed.

SMBus ARP capability can be disabled through the NVM.

### 11.5.5.3 SMBus ARP Flow

SMBus ARP flow is based on the status of two flags:

- **AV (Address Valid)** — This flag is set when the X550 has a valid SMBus address.
- **AR (Address Resolved)** — This flag is set when the X550 SMBus address is resolved (SMBus address was assigned by the SMBus ARP process).

These flags are internal X550 flags and are not exposed to external SMBus devices.

Since the X550 is a Persistent SMBus Address (PSA) device, the AV flag is always set, while the AR flag is cleared after power up until the SMBus ARP process completes. Since AV is always set, the X550 always has a valid SMBus address.

When the SMBus master needs to start an SMBus ARP process, it resets (in terms of ARP functionality) all devices on SMBus by issuing either Prepare to ARP or Reset Device commands. When the X550 accepts one of these commands, it clears its AR flag (if set from previous SMBus ARP process), but not its AV flag (the current SMBus address remains valid until the end of the SMBus ARP process).

Clearing the AR flag means that the X550 responds to SMBus ARP transactions that are issued by the master. The SMBus master issues a Get UDID command (general or directed) to identify the devices on the SMBus. The X550 always responds to the Directed command and to the General command only if its AR flag is not set.

After the Get UDID, The master assigns the X550 SMBus address by issuing an Assign Address command. The X550 checks whether the UDID matches its own UDID and if it matches, it switches its SMBus address to the address assigned by the command (byte 17). After accepting the Assign Address command, the AR flag is set and from this point (as long as the AR flag is set), the X550 does not respond to the Get UDID General command. Note that all other commands are processed even if the AR flag is set. If the address changed, from the one previously stored in the NVM, the X550 stores the SMBus address that was assigned in the SMBus ARP process in the NVM, so at the next power up, it returns to its assigned SMBus address. This process uses the NVM update flow described in [Section 3.4.2.1](#).

[Figure 11-4](#) shows the X550 SMBus ARP flow.

Figure 11-4. SMBus ARP Flow

### 11.5.5.4 SMBus ARP UDID Content

The UDID provides a mechanism to isolate each device for the purpose of address assignment. Each device has a unique identifier. The 128-bit number is comprised of the following fields:

**Table 11-8. UDID**

| 1 Byte                | 1 Byte                | 2 Bytes   | 2 Bytes   | 2 Bytes           | 2 Bytes             | 2 Bytes             | 4 Bytes               |
|-----------------------|-----------------------|-----------|-----------|-------------------|---------------------|---------------------|-----------------------|
| Device Capabilities   | Version/Revision      | Vendor ID | Device ID | Interface         | Subsystem Vendor ID | Subsystem Device ID | Vendor Specific ID    |
| See notes that follow | See notes that follow | 0x8086    | 0x1562    | 0x0004/<br>0x0024 | 0x0000              | 0x0000              | See notes that follow |
| MSB                   |                       |           |           |                   |                     |                     | LSB                   |

Where:

**Vendor ID:** The device manufacturer's ID as assigned by the SBS Implementers' Forum or the PCI SIG.

Constant value: 0x8086

**Device ID:** The device ID as assigned by the device manufacturer (identified by the *Vendor ID* field).

Constant value: 0x1562

**Interface:** Identifies the protocol layer interfaces supported over the SMBus connection by the device.

Bits 3:0 = 0x4 indicates SMBus Version 2.0

Bit 5 (ASF bit) = 1 in MCTP mode.

**Subsystem Fields:** These fields are not supported and return zeros.

**Device Capabilities:** Dynamic and Persistent Address, *PEC Support* bit:

| 7            | 6  | 5            | 4            | 3            | 2            | 1            | 0                  |
|--------------|----|--------------|--------------|--------------|--------------|--------------|--------------------|
| Address Type |    | Reserved (0) | Reserved (0) | Reserved (0) | Reserved (0) | Reserved (0) | PEC Supported      |
| 0b           | 1b | 0b           | 0b           | 0b           | 0b           | 0b           | 0b/1b <sup>1</sup> |
| MSB          |    |              |              |              |              |              | LSB                |

1. The value is set according to the *SMBus Transaction PEC* bit in the NVM

**Version/Revision:** UDID Version 1, Silicon Revision:

| 7            | 6            | 5            | 4 | 3 | 2                       | 1 | 0   |
|--------------|--------------|--------------|---|---|-------------------------|---|-----|
| Reserved (0) | Reserved (0) | UDID Version |   |   | Silicon Revision ID     |   |     |
| 0b           | 0b           | 001b         |   |   | See the following table |   |     |
| MSB          |              |              |   |   |                         |   | LSB |

Silicon Revision ID:

| Silicon Version | Revision ID |
|-----------------|-------------|
| A0              | 000b        |
| B0              | 001b        |

**Vendor Specific ID:** Four LSB bytes of the device Serial Number combined with the port number. The Serial Number is taken from the NVM and is reflected in the PCI\_SERL and PCI\_SERH registers.

| 1 Byte                                | 1 Byte              | 1 Byte              | 1 Byte              |
|---------------------------------------|---------------------|---------------------|---------------------|
| Port Number, MAC Address, Byte 3[6:0] | MAC Address, Byte 2 | MAC Address, Byte 1 | MAC Address, Byte 0 |
| MSB                                   |                     |                     | LSB                 |

### 11.5.5.5 SMBus ARP and Multi-Port

The X550 responds as two SMBus devices having two sets of AR/AV flags (one for each port). The X550 responds two time to the SMBus ARP master, once each for each port. All SMBus addresses are taken from the SMBus ARP address word of the NVM.

Note that the Unique Device Identifier (UDID) is different for the different ports in the *Version ID* field. The X550 first responds as port 0, and only when an address is assigned, then starts responding as port 1 to the Get UDID command.

### 11.5.5.6 Concurrent SMBus Transactions

The SMBus interface is single threaded. Thus, concurrent SMBus transactions are not permitted. Once a transaction is started, it must be completed before additional transaction can be initiated.

A transaction is defined as:

- All the SMBus commands used to receive a packet.
- All the SMBus commands used to send a packet.
- The read and write SMBus commands used as part of read parameters described in [Section 11.5.11.2](#).
- The single write SMBus commands described in [Section 11.5.11.1](#).

## 11.5.6 SMBus Notification Methods

The X550 supports three methods of notifying the BMC that it has information that needs to be read by the BMC:

- SMBus alert - Refer to [Section 11.5.6.1](#).
- Asynchronous notify - Refer to [Section 11.5.6.2](#).
- Direct receive - refer to [Section 11.5.6.3](#).

The notification method used by the X550 can be configured from the SMBus using the Receive Enable command ([Section 11.5.11.1.3](#)). The default method is set by the NVM in the *Notification Method* field in LAN Receive Enable 1 ([Section 6.5.3.17](#)).

**Note:** The SMBus notification method used must be the same for all ports.

The following events cause the X550 to send a notification event to the BMC:

- Receiving a LAN packet that is designated to the BMC.
- The firmware was reset and requires re-initialization.
- Receiving a Request Status command from the BMC initiates a status response.
- The X550 is configured to notify the BMC upon status changes (by setting the *EN\_STA* bit in the Receive Enable Command) and one of the following events happen:
  - TCO Command Aborted
  - Link Status changed
  - Power state change
  - Thermal Sensor Event

There can be cases where the BMC is hung and not responding to the SMBus notification. The X550 has a time-out value (defined in the NVM) to avoid hanging while waiting for the notification response. If the BMC does not respond until the time out expires, the notification is de-asserted and all pending data is silently discarded.

Note that the SMBus notification time-out value can only be set in the NVM. The BMC cannot modify this value.

### 11.5.6.1 SMBus Alert and Alert Response Method

The SMBus Alert# (SMBALERT\_N) signal is an additional SMBus signal that acts as an asynchronous interrupt signal to an external SMBus master. The X550 asserts this signal each time it has a message that it needs the BMC to read and if the chosen notification method is the SMBus alert method. Note that the SMBus alert method is an open-drain signal which means that other devices besides the X550 can be connected on the same alert pin. As a result, the BMC needs a mechanism to distinguish between the alert sources.

The BMC can respond to the alert by issuing an ARA Cycle command to detect the alert source device. The X550 responds to the ARA cycle with its own SMBus slave address (if it was the SMBus alert source) and de-asserts the alert when the ARA cycle is completes. Following the ARA cycle, the BMC issues a read command to retrieve the X550 message.

Some BMCs do not implement the ARA cycle transaction. These BMCs respond to an alert by issuing a Read command to the X550 (0xC0/0xD0 or 0xDE). The X550 always responds to a Read command, even if it is not the source of the notification. The default response is a status transaction. If the X550 is the source of the SMBus Alert, it replies the read transaction and then de-asserts the alert after the command byte of the read transaction.

**Note:** In SMBus Alert mode, the SMBALERT\_N pin is used for notification. Each port generate alerts on events that are independent of each other. If two ports have events to notify, the second alert is asserted only after the first event is handled. Hence, if an ARA cycle is not sent, a read status transaction should be done to all the ports in event of an ALERT\_N assertion.

**Note:**

The ARA cycle is an SMBus receive byte transaction to SMBus Address 0001-100b. Note that the ARA transaction does not support PEC. The ARA transaction format is as follows:

|   |                        |    |   |                                   |   |   |   |
|---|------------------------|----|---|-----------------------------------|---|---|---|
| 1 | 7                      | 1  | 1 | 8                                 | 1 | 1 | 1 |
| S | Alert Response Address | Rd | A | Slave Device Address              |   | A | P |
|   | 0001 100               | 1  | 0 | Manageability Slave SMBus Address | 0 | 1 |   |

If the BMC does not react to the alert in the delay defined by the *SMBus Notification Timeout* NVM field (Section 6.5.4.3), the ALERT pin is de-asserted and the Rx packet indication in the status word is cleared (and packet is dropped)

### 11.5.6.2 Asynchronous Notify Method

When configured using the asynchronous notify method, the X550 acts as a SMBus master and notifies the BMC of one of the events listed in Section 11.5.6 by issuing a modified form of the write word transaction. The asynchronous notify transaction SMBus address and data payload is configured using the Receive Enable command (Section 11.5.11.1.3) or using the NVM defaults. Note that the asynchronous notify is not protected by a PEC byte.

|   |                   |    |   |                         |   |   |               |   |                |   |   |
|---|-------------------|----|---|-------------------------|---|---|---------------|---|----------------|---|---|
| 1 | 7                 | 1  | 1 | 7                       | 1 | 1 | 8             | 1 | 8              | 1 | 1 |
| S | Target Address    | Wr | A | Sending Device Address  |   | A | Data Byte Low | A | Data Byte High | A | P |
|   | BMC Slave Address | 0  | 0 | MNG Slave SMBus Address | 0 | 0 | Interface     | 0 | Alert Value    | 0 |   |

The target address and data byte low/high are taken from the Receive Enable command or NVM configuration (Section 6.5.3.17 and Section 6.5.3.18).

If the BMC does not read the status in the delay defined by the *SMBus Notification Timeout* NVM field (Section 6.5.4.3), the Rx packet indication in the status word is cleared (and packet is dropped).

### 11.5.6.3 Direct Receive Method

If configured, the X550 has the capability to send a message it needs to transfer to the external BMC as a master over the SMBus instead of alerting the BMC and waiting for it to read the message.

The message format follows. Note that the command that is used is the same command that is used by the external BMC in the Block Read command. The opcode that the X550 puts in the data is also the same as it put in the Block Read command of the same functionality. The rules for the *F* and *L* flags (bits) are also the same as in the Block Read command.

|   |                   |    |   |            |           |                                 |   |     |
|---|-------------------|----|---|------------|-----------|---------------------------------|---|-----|
| 1 | 7                 | 1  | 1 | 1          | 1         | 6                               | 1 |     |
| S | Target Address    | Wr | A | F          | L         | Command                         | A | ... |
|   | BMC Slave Address | 0  | 0 | First Flag | Last Flag | Receive TCO Command<br>01 0000b | 0 |     |

|            |   |             |   |     |   |             |   |   |
|------------|---|-------------|---|-----|---|-------------|---|---|
| 8          | 1 | 8           | 1 |     | 1 | 8           | 1 | 1 |
| Byte Count | A | Data Byte 1 | A | ... | A | Data Byte N | A | P |
| N          | 0 |             | 0 |     | 0 |             | 0 |   |

## 11.5.7 Receive Pass-Through Flow

The X550 is used as a channel for receiving packets from the network link and passing them to the external BMC. The BMC configures the X550 to pass these specific packets to the BMC. Once a full packet is received from the link and identified as a manageability packet that should be transferred to the BMC, the X550 starts the receive TCO flow to the BMC.

The X550 uses the SMBus notification method to notify the BMC that it has data to deliver. Since the packet size might be larger than the maximum SMBus fragment size, the packet is divided into fragments, where the X550 uses the maximum fragment size allowed in each fragment (configured via the NVM). The last fragment of the packet transfer is always the status of the packet. As a result, the packet is transferred in at least two fragments. The data of the packet is transferred as part of the receive TCO LAN packet transaction.

When SMBus alert is selected as the BMC notification method, the X550 notifies the BMC on each fragment of a multi-fragment packet. When asynchronous notify is selected as the BMC notification method, the X550 notifies the BMC only on the first fragment of a received packet. It is the BMC's responsibility to read the full packet including all the fragments.

Any timeout on the SMBus notification results in discarding the entire packet. Any NACK by the BMC causes the fragment to be re-transmitted to the BMC on the next Receive Packet command.

The maximum size of the received packet is limited by the X550 to 1536 bytes. Packets larger than 1536 bytes are silently discarded. Any packet smaller than 1536 bytes is processed.

## 11.5.8 Transmit Pass-Through Flow

The X550 is used as the channel for transmitting packets from the external BMC to the network link. The network packet is transferred from the BMC over the SMBus and then, when fully received by the X550, is transmitted over the network link.

Each SMBus address is connected to a different LAN port. When a packet is received during a SMBus transaction using SMBus address #0, it is transmitted to the network using LAN port #0; it is transmitted through LAN port #1 if received on SMBus address #1, etc.

The X550 supports packets up to an Ethernet packet length of 1536 bytes. Since SMBus transactions can only be up to 240 bytes in length, packets might need to be transferred over the SMBus in more than one fragment. This is achieved using the *F* and *L* bits in the command number of the transmit TCO packet Block Write command. When the *F* bit is set, it is the first fragment of the packet. When the *L* bit is set, it is the last fragment of the packet. When both bits are set, the entire packet is in one fragment. The packet is sent over the network link only after all its fragments are received correctly over the SMBus. The maximum SMBus fragment size is defined within the NVM and cannot be changed by the BMC.

The minimum packet length defined by the 802.3 specification is 64 bytes. The X550 pads packets that are less than 64 bytes to meet the specification requirements (there is no need for the external BMC to pad packets less than 64 bytes). If the packet sent by the BMC is larger than 1536 bytes, the X550 silently discards the packet.

The X550 calculates the L2 CRC on the transmitted packet and adds its four bytes at the end of the packet. Any other packet field (such as XSUM or VLAN) must be calculated and inserted by the BMC (the X550 does not change any field in the transmitted packet, other than adding padding and CRC bytes).

If the network link is down when the X550 has received the last fragment of the packet from the BMC, it silently discards the packet. Note that any link down event during the transfer of any packet over the SMBus does not stop the operation since the X550 waits for the last fragment to end to see whether the network link is up again.

### 11.5.8.1 Transmit Errors in Sequence Handling

Once a packet is transferred over the SMBus from the BMC to the X550, the *F* and *L* flags should follow specific rules. The *F* flag defines the first fragment of the packet; the *L* flag that the transaction contains the last fragment of the packet. Table 11-9 lists the different flag options in transmit packet transactions.

**Table 11-9. Flag Options During Transmit Packet Transactions**

| Previous | Current   | Action/Notes                                                                                                                                          |
|----------|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| Last     | First     | Accept both.                                                                                                                                          |
| Last     | Not First | Error for the current transaction. Current transaction is discarded and an abort status is asserted.                                                  |
| Not Last | First     | Error in previous transaction. Previous transaction (until previous First) is discarded. Current packet is processed.<br>No abort status is asserted. |
| Not Last | Not First | Process the current transaction.                                                                                                                      |

**Note:** Since every other Block Write command in TCO protocol has both *F* and *L* flags on, they cause flushing any pending transmit fragments that were previously received. When running the TCO transmit flow, no other Block Write transactions are allowed in between the fragments.

### 11.5.8.2 TCO Command Aborted Flow

The X550 indicates to the BMC an error or an abort condition by setting the *TCO Abort* bit in the general status. The X550 might also be configured to send a notification to the BMC (see [Section 11.5.11.1.3.3](#)).

Following is a list of possible error and abort conditions:

- Any error in the SMBus protocol (NACK, SMBus timeouts, etc.).
- If the BMC does not respond until the notification timeout (programmed in the EEPROM) expires.
- Any error in compatibility between required protocols to specific functionality (for example, Rx Enable command with a byte count not equal to 1/14, as defined in the command specification).
- If the X550 does not have space to store the transmitted packet from the BMC (in its internal buffer space) before sending it to the link, the packet is discarded and the external BMC is notified via the *Abort* bit.
- Error in the *F/L* bit sequence during multi-fragment transactions.
- An internal reset to the X550's firmware.

## 11.5.9 SMBus Link State Control

While in SMBus mode, the default setting of the link is defined by the *Enable All PHYs in D3 N* bit in *Common Firmware Parameters* NVM word.

When a channel is enabled through NVM setting or through the *RCV\_EN* option of the Receive Enable Command, the link is established (if not already required for other purposes).

If the channel is disabled by clearing of the *RCV\_EN* option, the link may move back to the default defined by the *Enable All PHYs in D3 N* if not needed for other purposes.

**Note:** When the link is taken down due to *RCV\_EN* being cleared the transmit traffic from BMC is also stopped.

**Note:** Before transitioning to D3 it is the responsibility of the driver to request the PHY to be active for wake-up activities.

## 11.5.10 SMBus ARP Transactions

All SMBus ARP transactions include the PEC byte.

### 11.5.10.1 Prepare to ARP

This command clears the *Address Resolved* flag (set to false). It does not affect the status or validity of the dynamic SMBus address and is used to inform all devices that the ARP master is starting the ARP process:

|   |               |    |   |           |   |                        |   |   |
|---|---------------|----|---|-----------|---|------------------------|---|---|
| 1 | 7             | 1  | 1 | 8         | 1 | 8                      | 1 | 1 |
| S | Slave Address | Wr | A | Command   | A | PEC                    | A | P |
|   | 1100 001      | 0  | 0 | 0000 0001 | 0 | [Data Dependent Value] | 0 |   |

### 11.5.10.2 Reset Device (General)

This command clears the *Address Resolved* flag (set to false). It does not affect the status or validity of the dynamic SMBus address.

|   |               |    |   |           |   |                        |   |   |
|---|---------------|----|---|-----------|---|------------------------|---|---|
| 1 | 7             | 1  | 1 | 8         | 1 | 8                      | 1 | 1 |
| S | Slave Address | Wr | A | Command   | A | PEC                    | A | P |
|   | 1100 001      | 0  | 0 | 0000 0010 | 0 | [Data Dependent Value] | 0 |   |

### 11.5.10.3 Reset Device (Directed)

The *Command* field is NACKed if bits 7:1 do not match the current SMBus address. This command clears the *Address Resolved* flag (set to false) and does not affect the status or validity of the dynamic SMBus address.

|   |               |    |   |                            |   |                        |   |   |
|---|---------------|----|---|----------------------------|---|------------------------|---|---|
| 1 | 7             | 1  | 1 | 8                          | 1 | 8                      | 1 | 1 |
| S | Slave Address | Wr | A | Command                    | A | PEC                    | A | P |
|   | 1100 001      | 0  | 0 | Targeted Slave Address   0 | 0 | [Data Dependent Value] | 0 |   |

### 11.5.10.4 Assign Address

This command assigns SMBus address. The address and command bytes are always acknowledged.

The transaction is aborted (NACKed) immediately if any of the UDID bytes is different from the X550 UDID bytes. If successful, the manageability system internally updates the SMBus address. This command also sets the *Address Resolved* flag (set to true).

|   |               |    |   |           |   |            |   |     |
|---|---------------|----|---|-----------|---|------------|---|-----|
| 1 | 7             | 1  | 1 | 8         | 1 | 8          | 1 |     |
| S | Slave Address | Wr | A | Command   | A | Byte Count | A | ... |
|   | 1100 001      | 0  | 0 | 0000 0100 | 0 | 0001 0001  | 0 |     |

|                    |   |              |   |              |   |              |   |     |
|--------------------|---|--------------|---|--------------|---|--------------|---|-----|
| 8                  | 1 | 8            | 1 | 8            | 1 | 8            | 1 |     |
| Data 1             | A | Data 2       | A | Data 3       | A | Data 4       | A | ... |
| UDID Byte 15 (MSB) | 0 | UDID Byte 14 | 0 | UDID Byte 13 | 0 | UDID Byte 12 | 0 |     |

|              |   |              |   |             |   |             |   |     |
|--------------|---|--------------|---|-------------|---|-------------|---|-----|
| 8            | 1 | 8            | 1 | 8           | 1 | 8           | 1 |     |
| Data 5       | A | Data 6       | A | Data 7      | A | Data 8      | A | ... |
| UDID Byte 11 | 0 | UDID Byte 10 | 0 | UDID Byte 9 | 0 | UDID Byte 8 | 0 |     |

|             |   |             |   |             |   |     |
|-------------|---|-------------|---|-------------|---|-----|
| 8           | 1 | 8           | 1 | 8           | 1 |     |
| Data 9      | A | Data 10     | A | Data 11     | A | ... |
| UDID Byte 7 | 0 | UDID Byte 6 | 0 | UDID Byte 5 | 0 |     |

|             |   |             |   |             |   |             |   |     |
|-------------|---|-------------|---|-------------|---|-------------|---|-----|
| 8           | 1 | 8           | 1 | 8           | 1 | 8           | 1 |     |
| Data 12     | A | Data 13     | A | Data 14     | A | Data 15     | A | ... |
| UDID Byte 4 | 0 | UDID Byte 3 | 0 | UDID Byte 2 | 0 | UDID Byte 1 | 0 |     |

|                   |   |                  |   |                        |   |   |
|-------------------|---|------------------|---|------------------------|---|---|
| 8                 | 1 | 8                | 1 | 8                      | 1 | 1 |
| Data 16           | A | Data 17          | A | PEC                    | A | P |
| UDID Byte 0 (LSB) | 0 | Assigned Address | 0 | [Data Dependent Value] | 0 |   |

### 11.5.10.5 Get UDID (General and Directed)

The general get UDID SMBus transaction supports a constant command value of 0x03 and, if directed, supports a Dynamic command value equal to the dynamic SMBus address.

If the SMBus address has been resolved (*Address Resolved* flag set to true), the manageability system does not acknowledge (NACK) this transaction. If it's a General command, the manageability system always acknowledges (ACKs) as a directed transaction.

This command does not affect the status or validity of the dynamic SMBus address or the *Address Resolved* flag.

| S | Slave Address | Wr | A | Command   | A | S | ... |
|---|---------------|----|---|-----------|---|---|-----|
|   | 1100 001      | 0  | 0 | See Below | 0 |   |     |

| 7             | 1  | 1 | 8          | 1 |     |
|---------------|----|---|------------|---|-----|
| Slave Address | Rd | A | Byte Count | A | ... |
| 1100 001      | 1  | 0 | 0001 0001  | 0 |     |

| 8                  | 1 | 8            | 1 | 8            | 1 | 8            | 1 |     |
|--------------------|---|--------------|---|--------------|---|--------------|---|-----|
| Data 1             | A | Data 2       | A | Data 3       | A | Data 4       | A | ... |
| UDID Byte 15 (MSB) | 0 | UDID Byte 14 | 0 | UDID Byte 13 | 0 | UDID Byte 12 | 0 |     |

| 8            | 1 | 8            | 1 | 8           | 1 | 8           | 1 |     |
|--------------|---|--------------|---|-------------|---|-------------|---|-----|
| Data 5       | A | Data 6       | A | Data 7      | A | Data 8      | A | ... |
| UDID Byte 11 | 0 | UDID Byte 10 | 0 | UDID Byte 9 | 0 | UDID Byte 8 | 0 |     |

| 8           | 1 | 8           | 1 | 8           | 1 |     |
|-------------|---|-------------|---|-------------|---|-----|
| Data 9      | A | Data 10     | A | Data 11     | A | ... |
| UDID Byte 7 | 0 | UDID Byte 6 | 0 | UDID Byte 5 | 0 |     |

| 8           | 1 | 8           | 1 | 8           | 1 | 8           | 1 |     |
|-------------|---|-------------|---|-------------|---|-------------|---|-----|
| Data 12     | A | Data 13     | A | Data 14     | A | Data 15     | A | ... |
| UDID Byte 4 | 0 | UDID Byte 3 | 0 | UDID Byte 2 | 0 | UDID Byte 1 | 0 |     |

| 8                 | 1 | 8                    | 1 | 8                      | 1  | 1 |
|-------------------|---|----------------------|---|------------------------|----|---|
| Data 16           | A | Data 17              | A | PEC                    | ~Ä | P |
| UDID Byte 0 (LSB) | 0 | Device Slave Address | 0 | [Data Dependent Value] | 1  |   |

The Get UDID command depends on whether this is a Directed or General command.

The General Get UDID SMBus transaction supports a constant command value of 0x03.

The Directed Get UDID SMBus transaction supports a Dynamic command value equal to the dynamic SMBus address with the LSB bit set.

**Note:** Bit 0 (LSB) of Data byte 17 is always 1b.

## 11.5.11 SMBus Pass-Through Transactions

This section details commands (both read and write) that the X550 SMBus interface supports for pass-through.

### 11.5.11.1 Write SMBus Transactions

This section details the commands that the BMC can send to the X550 over the SMBus interface. The SMBus write transactions table lists the different SMBus write transactions supported by the X550.

| TCO Command                      | Transaction | Command                                   | Fragmentation | Page |
|----------------------------------|-------------|-------------------------------------------|---------------|------|
| Transmit Packet                  | Block Write | First: 0x84<br>Middle: 0x04<br>Last: 0x44 | Multiple      | 871  |
| Transmit Packet                  | Block Write | Single: 0xC4                              | Single        | 871  |
| Request Status                   | Block Write | Single: 0xDD                              | Single        | 872  |
| Receive Enable                   | Block Write | Single: 0xCA                              | Single        | 872  |
| Force TCO                        | Block Write | Single: 0xCF                              | Single        | 874  |
| Management Control               | Block Write | Single: 0xC1                              | Single        | 875  |
| Update MNG RCV Filter Parameters | Block Write | Single: 0xCC                              | Single        | 875  |
| Set Common Filters               | Block Write | Single: 0xC2                              | Single        | 877  |
| Clear All Filters                | Block Write | Single: 0xC3                              | Single        | 880  |

#### 11.5.11.1.1 Transmit Packet Command

The Transmit Packet command behavior is detailed in [Section 11.5.8](#). The Transmit Packet fragments have the following format.

The payload length is limited to the maximum payload length set in the NVM. If the overall packet length is bigger than 1536 bytes, the packet is silently discarded.

| Function                 | Command | Byte Count | Data 1          | ... | Data N          |
|--------------------------|---------|------------|-----------------|-----|-----------------|
| Transmit first fragment  | 0x84    | N          | Packet data MSB | ... | Packet data LSB |
| Transmit middle fragment | 0x04    |            |                 |     |                 |
| Transmit last fragment   | 0x44    |            |                 |     |                 |
| Transmit single fragment | 0xC4    |            |                 |     |                 |

### 11.5.11.1.2 Request Status Command

An external BMC can initiate a request to read the X550 manageability status by sending a Request Status command. When received, the X550 initiates a notification to an external BMC when status is ready. After this, the external controller is able to read the status, by issuing a read status command (see [Section 11.5.11.2.2](#)).

The format is as follows:

| Function       | Command | Byte Count | Data 1 |
|----------------|---------|------------|--------|
| Request Status | 0xDD    | 1          | 0      |

### 11.5.11.1.3 Receive Enable Command

The Receive Enable command is a single fragment command used to configure the X550. This command has two formats: short, 1-byte legacy format (providing backward compatibility with previous components) and long, 14-byte advanced format (allowing greater configuration capabilities). The Receive Enable command format is as follows:

| Function                | CMD  | Byte Count | Data 1               | Data 2       | ... | Data 7       | Data 8      | ... | Data 11     | Data 12        | Data 13       | Data 14          |
|-------------------------|------|------------|----------------------|--------------|-----|--------------|-------------|-----|-------------|----------------|---------------|------------------|
| Legacy Receive Enable   | 0xCA | 1          | Receive Control Byte | -            | ... | -            | -           | ... | -           | -              | -             | -                |
| Advanced Receive Enable |      | 14 (0x0E)  |                      | MAC Addr MSB |     | MAC Addr LSB | IP Addr MSB |     | IP Addr LSB | BMC SMBus Addr | I/F Data Byte | Alert Value Byte |

| Field   | Bit(s) | Description                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RCV_EN  | 0      | Receive TCO Enable.<br>0b = Disable receive TCO packets.<br>1b = Enable Receive TCO packets.<br>Setting this bit enables all manageability receive filtering operations. Enabling specific filters is done via the NVM or through special configuration commands.<br><b>Note:</b> When the RCV_EN bit is cleared, all receive TCO functionality is disabled, not just the packets that are directed to the BMC (also auto ARP packets). |
| RCV_ALL | 1      | Receive All Enable.<br>0b = Disable receiving all packets.<br>1b = Enable receiving all packets.<br>Forwards all packets received over the wire that passed L2 filtering to the external BMC. This flag has no effect if bit 0 (Enable TCO packets) is disabled.                                                                                                                                                                        |
| EN_STA  | 2      | Enable Status Reporting.<br>0b = Disable status reporting.<br>1b = Enable status reporting.                                                                                                                                                                                                                                                                                                                                             |

| Field      | Bit(s) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EN_ARP_RES | 3      | <p>Enable ARP Response.</p> <p>0b = Disable the X550 ARP response — The X550 treats ARP packets as any other packet, for example, packet is forwarded to the BMC if it passed other (non-ARP) filtering.</p> <p>1b = Enable the X550 ARP response — The X550 automatically responds to all received ARP requests that match the IP Address programmed by the BMC. The BMC IP Address is provided as part of the Receive Enable message (bytes 8:11). If a short version of the command is used, the X550 uses IP Address configured in the most recent long version of the command in which the <i>EN_ARP_RES</i> bit was set. If no such previous long command exists, the X550 uses the IP Address configured in the NVM as ARP Response IPv4 Address in the pass-through LAN configuration structure.</p> <p>If the <i>CBDM</i> bit is set, the X550 uses the BMC dedicated MAC Address in ARP response packets. If the <i>CBDM</i> bit is not set, the BMC uses the host MAC Address.</p> <p>When the ARP offload feature is activated, the X550 uses the following registers to filter the ARP traffic addressed to the BMC. BMC should not modify these registers:</p> <p>Manageability Decision Filter – MDEF6 (and corresponding bit 6 in Management Only traffic Register – <i>MNGONLY</i>).</p> <p>IPv4 address - MIPAF4[3]</p> |
| NM         | 5:4    | <p>Notification Method. Define the notification method the X550 uses.</p> <p>00b = SMBUS Alert.</p> <p>01b = Asynchronous notify.</p> <p>10b = Direct receive.</p> <p>11b = Not supported.</p> <p>Changing the notification method in any port updates the notification method of all ports.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Reserved   | 6      | Reserved. Must be set to 1b.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| CBDM       | 7      | <p>Configure the BMC Dedicated MAC Address.</p> <p><b>Note:</b> This bit should be 0b when the <i>RCV_EN</i> bit (bit 0) is not set.</p> <p>0b = The X550 shares the MAC Address for MNG traffic with the host MAC Address, which is specified in NVM words 0x0-0x2.</p> <p>1b = The X550 uses the BMC dedicated MAC Address as a filter for incoming receive packets.</p> <p>The BMC MAC Address is set in bytes 2-7 in this command.</p> <p>If a short version of the command is used, the X550 uses the MAC Address configured in the most recent long version of the command in which the <i>CBDM</i> bit was set.</p> <p>When the dedicated MAC Address feature is activated, the X550 uses the following registers to filter in all the traffic addressed to the BMC MAC. BMC should not modify these registers:</p> <p>Manageability Decision Filter – MDEF7 (and corresponding bit 7 in Management Only traffic Register – <i>MNGONLY</i>)</p> <p>Manageability MAC Address Low – <i>MMAL</i>[3]</p> <p>Manageability MAC Address High – <i>MAAH</i>[3]</p> <p>When the dedicated MAC Address feature is cleared, these registers are not programmed and the BMC may use other filters to enforce MAC filtering using the Update Management Receive Filter Parameters command.</p>                                                |

#### 11.5.11.1.3.1 Management MAC Address (Data Bytes 7:2)

Ignored if the *CBDM* bit is not set. This MAC Address is used to configure the dedicated MAC Address. In addition, it is used in the ARP response packet when the *EN\_ARP\_RES* bit is set. This MAC Address is also used when *CBDM* bit is set in subsequent short versions of this command.

#### 11.5.11.1.3.2 Management IP Address (Data Bytes 11:8)

This IP Address is used to filter ARP request packets.

#### 11.5.11.1.3.3 Asynchronous Notification SMBus Address (Data Byte 12)

This address is used for the asynchronous notification SMBus transaction and for direct receive. The SMBus address is stored in bit 7:1 of this byte. Bit 0 is always 0b.

#### 11.5.11.1.3.4 Interface Data (Data Byte 13)

Interface data byte used in asynchronous notification.

#### 11.5.11.1.3.5 Alert Value Data (Data Byte 14)

Alert Value data byte used in asynchronous notification.

### 11.5.11.1.4 Force TCO Command

This command causes the X550 to perform a TCO reset, TCO isolate, or firmware reset.

#### TCO Reset:

The Force TCO reset clears the data path (Rx/Tx) of the X550 to enable the BMC to transmit/receive packets through the X550 by assertion of a global reset. Force TCO reset is asserted only to the port related to the SMBus address the command. This command should only be used when the BMC is unable to transmit receive and suspects that the X550 is inoperable. The command also causes the LAN device driver to unload. It is recommended to perform a system restart to resume normal operation.

#### Firmware Reset:

This command causes re-initialization of all the embedded controller functions and re-load of related NVM words. A firmware reset is achieved by setting the GSCR.SET\_FWRST Aux bit.

The X550 considers the Force TCO reset command as an indication that the operating system is hung. The Force TCO command format is as follows:

| Function        | Command | Byte Count | Data 1   |
|-----------------|---------|------------|----------|
| Force TCO Reset | 0xCF    | 1          | TCO Mode |

Where TCO Mode is:

| Field                       | Bit(s) | Description                                                                                                                                                                                                                                        |
|-----------------------------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DO_TCO_RST                  | 0      | Perform TCO Reset.<br>0b = Do nothing.<br>1b = Perform TCO reset.                                                                                                                                                                                  |
| DO_TCO_ISOLATE <sup>1</sup> | 1      | Do TCO Isolate<br>0b = Enable PCIe write access to LAN port.<br>1b = Isolate Host PCIe write operation to the port<br><b>Note:</b> Should be used for debug only.                                                                                  |
| RESET_MGMT                  | 2      | Reset manageability; re-load manageability NVM words.<br>0b = Do nothing.<br>1b = Issue firmware reset to manageability.<br>Setting this bit generates a one-time firmware reset. Following the reset, management related data from NVM is loaded. |
| Reserved                    | 7:3    | Reserved (set to 0x00).                                                                                                                                                                                                                            |

1. TCO Isolate Host Write operation enabled in NVM.

**Note:** Only one of the fields should be set in a given command. Setting more than one field may yield unexpected results.

### 11.5.11.1.5 Management Control

This command is used to set generic manageability parameters. The parameters list is shown in [Table 11-10](#). The command is 0xC1 stating that it is a Management Control command. The first data byte is the parameter number and the data afterwards (length and content) are parameter specific as shown in Management Control Command Parameters/Content.

**Note:** If the parameter that the BMC sets is not supported by the X550. The X550 does not NACK the transaction. After the transaction ends, the X550 discards the data and asserts a transaction abort status.

The Management Control command format is as follows:

| Function           | Command | Byte Count | Data 1           | Data 2              | ... | Data N |
|--------------------|---------|------------|------------------|---------------------|-----|--------|
| Management Control | 0xC1    | N          | Parameter Number | Parameter Dependent |     |        |

**Table 11-10. Management Control Command Parameters/Content**

| Parameter        | #    | Parameter Data                                                                                                                                                                                                                                                                                                                             |
|------------------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Keep PHY Link Up | 0x00 | <p>A single byte parameter.</p> <p>Data 2:</p> <p>Bit 0: Set to indicate that the PHY link for this port should be kept up throughout system resets. This is useful when the server is reset and the BMC needs to keep connectivity for a manageability session.</p> <p>Bit [7:1] Reserved.</p> <p>0b = Disabled.</p> <p>1b = Enabled.</p> |

### 11.5.11.1.6 Update Management Receive Filter Parameters

This command is used to set the manageability receive filters parameters. The command is 0xCC. The first data byte is the parameter number and the data that follows (length and content) are parameter specific as listed in management RCV filter parameters.

If the parameter that the BMC sets is not supported by the X550, the X550 does not NACK the transaction. After the transaction ends, the X550 discards the data and asserts a transaction abort status.

The update management RCV receive filter parameters command format is as follows:

| Function                               | Command | Byte Count | Data 1           | Data 2              | ... | Data N |
|----------------------------------------|---------|------------|------------------|---------------------|-----|--------|
| Update Manageability Filter Parameters | 0xCC    | N          | Parameter Number | Parameter Dependent |     |        |

[Table 11-11](#) lists the different parameters and their content.

**Table 11-11. Management Receive Filter Parameters**

| Parameter                            | Number | Parameter Data                                                                                                                                                                                                                                                                                                                     |
|--------------------------------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Filters Enables                      | 0x1    | Defines the generic filters configuration. The structure of this parameter is four bytes as the Manageability Control (MANC) register (see <a href="#">Table 11-12</a> ).<br><b>Note:</b> The general filter enable is in the Receive Enable command that enables receive filtering.                                               |
| MNGONLY configuration                | 0xF    | This parameter defines which of the packets types identified as manageability packets in the receive path is never directed to the host memory.<br>Data 2:5 = MNGONLY register bytes (see <a href="#">Section 8.2.2.19.8</a> ) - Data 2 is the MSB.                                                                                |
| Flex Filter 0 Enable Mask and Length | 0x10   | Flex Filter 0 Mask.<br>Data 17:2 = Mask. Bit 0 in data 2 is the first bit of the mask.<br>Data 19:18 = Reserved. Should be set to 00b.<br>Data 20 = Flexible filter length.                                                                                                                                                        |
| Flex Filter 0 Data                   | 0x11   | Data 2 — Group of flex filter's bytes:<br>0x0 = bytes 0-29<br>0x1 = bytes 30-59<br>0x2 = bytes 60-89<br>0x3 = bytes 90-119<br>0x4 = bytes 120-127<br>Data 3:32 = Flex filter data bytes. Data 3 is LSB.<br>Group's length is not a mandatory 30 bytes; it might vary according to filter's length and must NOT be padded by zeros. |
| Decision Filters                     | 0x61   | This command is obsolete and should not be used anymore. Use 0x68 instead.                                                                                                                                                                                                                                                         |
| VLAN Filters                         | 0x62   | 3 bytes are required to load the VLAN tag filters.<br>Data 2 = VLAN filter number.<br>Data 3 = MSB of VLAN filter.<br>Data 4 = LSB of VLAN filter.                                                                                                                                                                                 |
| Flex Port Filters                    | 0x63   | 3 to 4 bytes are required to load the manageability flex port filters.<br>Data 2 = Flex port filter number.<br>Data 3 = MSB of flex port filter.<br>Data 4 = LSB of flex port filter.                                                                                                                                              |
| IPv4 Filters                         | 0x64   | 5 bytes are required to load the IPv4 address filter.<br>Data 2 = IPv4 address filter number (3:0).<br>Data 3 = LSB of IPv4 address filter.<br>...<br>Data 6 = MSB of IPv4 address filter.                                                                                                                                         |
| IPv6 Filters                         | 0x65   | 17 bytes are required to load the IPv6 address filter.<br>Data 2 = IPv6 address filter number (3:0).<br>Data 3 = LSB of IPv6 address filter.<br>...<br>Data 18 = MSB of IPv6 address filter.                                                                                                                                       |
| MAC Filters                          | 0x66   | 7 bytes are required to load the MAC Address filters.<br>Data 2 = MAC Address filters pair number (3:0).<br>Data 3 = MSB of MAC Address.<br>...<br>Data 8 = LSB of MAC Address.                                                                                                                                                    |
| EtherType Filters                    | 0x67   | 5 bytes to load EtherType Filters (METF)<br>Data 2 = METF filter index (valid values are 0, 1, 2, 3).<br>Data 3 = MSB of METF.<br>...<br>Data 6 = LSB of METF.                                                                                                                                                                     |

**Table 11-11. Management Receive Filter Parameters (Continued)**

| Parameter                | Number | Parameter Data                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Extended Decision Filter | 0x68   | 9 bytes to load the extended decision filters (MDEF_EXT & MDEF)<br>Data 2 — MDEF filter index (valid values are 0...5).<br>Data 3 — MSB of MDEF_EXT (DecisionFilter1).<br>...<br>Data 6 — LSB of MDEF_EXT (DecisionFilter1).<br>Data 7 — MSB of MDEF (DecisionFilter0).<br>...<br>Data 10 — LSB of MDEF (DecisionFilter0).<br>The command overwrites any previously stored value. |

**Table 11-12. Filter Enable Parameters**

| Bit   | Name                         | Description                                                                                                                                                                                                                                                                                                               |

| 22:19 | Reserved                     | Reserved.                                                                                                                                                                                                                                                                                                                 |
| 23    | Enable Xsum Filtering to MNG | When this bit is set, only packets that pass the L3 and L4 checksum are send to the manageability block.                                                                                                                                                                                                                  |
| 24    | EN_IPV4_FILTER               | Enable IPv4 address Filters<br>0b = These bits store a single IPv6 filter.<br>1b = The last 128 bits of the MIPAF register are used to store 4 IPv4 addresses for IPv4 filtering.                                                                                                                                         |
| 25    | FIXED_NET_TYPE               | Fixed Net Type<br>0b = Both tagged and un-tagged packets can be forwarded to the manageability engine.<br>1b = Only packets matching the net type defined by the <i>NET_TYPE</i> field passes to manageability.                                                                                                           |
| 26    | NET_TYPE                     | Net Type<br>0b = Pass only un-tagged packets.<br>1b = Pass only VLAN tagged packets.<br>Valid only if <i>FIXED_NET_TYPE</i> is set.                                                                                                                                                                                       |
| 31:27 | Reserved                     | Reserved.                                                                                                                                                                                                                                                                                                                 |

### 11.5.11.1.7 Set Common Filters Command

The Set Common Filters command is a single fragment command capable of configuring the most common filters.

**Note:** If this command is used, all the other commands that programs forwarding filters should not be used (apart from the Clear All Filters command). When this command is received, an implied Clear All Filters command is done before the application of this command.

The Set Common Filters command has two possible formats:

**IPv4 Format:**

| Function           | Command | Byte Count | Data       |                                   |             |                   |                     |                  |              |
|--------------------|---------|------------|------------|-----------------------------------|-------------|-------------------|---------------------|------------------|--------------|
|                    |         |            | 1          | 2:4                               | 5:10        | 11                | 12                  | 13               | 14:17        |
| Set Common Filters | 0xC2    | 17         | Opcode = 0 | Receive Control (see Table 11-13) | MAC Address | BMC Alert Address | Interface Data Byte | Alert Value Byte | IPv4 Address |

**IPv6 Format:**

| Function           | Command | Byte Count | Data       |                                   |             |                   |                     |                  |              |
|--------------------|---------|------------|------------|-----------------------------------|-------------|-------------------|---------------------|------------------|--------------|
|                    |         |            | 1          | 2:4                               | 5:10        | 11                | 12                  | 13               | 14:29        |
| Set Common Filters | 0xC2    | 29         | Opcode = 0 | Receive Control (see Table 11-13) | MAC Address | BMC Alert Address | Interface Data Byte | Alert Value Byte | IPv6 Address |

**Table 11-13. Set Common Filters Receive Control Bytes**

| Byte | Bit | Field                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------|-----|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1    | 0   | RCV_EN                       | Receive TCO Packets Enabled.<br>1b = Enables the receive flow to the manageability block.<br>This bit should be set only if at least one of <i>EN_BMC2O</i> or <i>EN_BMC2NET</i> bits are set.                                                                                                                                                                                                                                                                                                                                                                                       |
|      | 1   | EN_STA                       | Enable Status Reporting.<br>0b = Disable status reporting.<br>1b = Enable status reporting.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|      | 2   | Auto ARP                     | Automatically respond to ARP packets.<br>Ignored in IPv6 mode. If this bit is set, broadcast ARP packets are handled by the X550 and ARP requests to the IP Address set in the command are responded.<br>Mutually exclusive to <i>Configure ARP/ Neighborhood Filter</i> bit.<br>If this bit is set, the IP Address must be valid and contain the IP Address of the MC.<br>This bit is ignored if <i>RCV_EN</i> is cleared.<br>When set, ARP requests to the BMC IP defined below (unicast or Broadcast) are sent to the internal firmware for processing. ARP response are dropped. |
|      | 3   | Enable Xsum Filtering to MNG | When this bit is set, only packets that pass the L3 and L4 checksum are send to the manageability block.<br>This bit is ignored if <i>RCV_EN</i> is cleared.                                                                                                                                                                                                                                                                                                                                                                                                                         |
|      | 5:4 | Reserved                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|      | 7:6 | Notification Method          | Notification Method. Define the notification method the X550 uses.<br>00b = SMBUS Alert.<br>01b = Asynchronous notify.<br>10b = Direct receive.<br>11b = Not supported.                                                                                                                                                                                                                                                                                                                                                                                                              |

Table 11-13. Set Common Filters Receive Control Bytes (Continued)

| Byte | Bit   | Field                                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------|-------|------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2    | 8     | CBDM                                                 | Configure the BMC Dedicated MAC Address.<br>0b = The X550 shares the MAC Address for MNG traffic with the host MAC Address, which is specified in RAH/RAL[0] registers<br>1b = The X550 uses the BMC dedicated MAC Address as a filter for incoming receive packets.<br>The BMC MAC Address is set in bytes 5-10 in this command.<br>This bit is ignored if <i>RCV_EN</i> is cleared.<br>If this bit is cleared, at least one of bits 9,10 or 11 must be set. If only bit 9 is set, the IP Address should be different than the address used by the host.                                                                                                                                                                                                                                                                                                      |
|      | 9     | Configure IP Address Filter                          | Automatically configure an IP Address Filter. If this bit is set, only packets matching this IP Address and the MAC Address defined by the <i>CBDM</i> bit are forwarded. This bit is ignored if <i>RCV_EN</i> is cleared.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|      | 10    | Configure RMCP 26Fh Filter                           | Automatically configure standard IPMI port 26Fh filters. If this bit is set, only packets matching this port and the MAC Address defined by the <i>CBDM</i> bit are forwarded. If the <i>Configure IP Address Filter</i> bit is set, only packets matching the IP Address and this port are forwarded. The other port enable bit (11) may add additional forwarding condition.<br>This bit is ignored if <i>RCV_EN</i> is cleared.                                                                                                                                                                                                                                                                                                                                                                                                                             |
|      | 11    | Configure RMCP 298h Filter                           | Automatically configure standard IPMI port 298h filter. If this bit is set, only packets matching this port and the MAC Address defined by the <i>CBDM</i> bit are forwarded. If the <i>Configure IP Address Filter</i> bit is set, only packets matching the IP Address and this port are forwarded. The other port enable bit (10) may add additional forwarding condition.<br>This bit is ignored if <i>RCV_EN</i> is cleared.                                                                                                                                                                                                                                                                                                                                                                                                                              |
|      | 12    | Configure ARP/ Neighborhood Filter                   | Automatically Configure filters to allow this traffic to BMC (mutually exclusive to <i>Auto ARP</i> bit). If this bit is set, broadcast or unicast ARP packets are forwarded to BMC. These packets may be sent to the host also.<br>In IPv4 mode, setting this bit allows forwarding of broadcast or unicast ARP request and response. If IP Address is set, only request or response to this address is forwarded.<br>In IPv6 mode, setting this bit allows forwarding of all types of neighbor discovery and MLD ICMPv6 packet types:<br>0x86 (134d) - Router Advertisement.<br>0x87 (135d) - Neighbor Solicitation.<br>0x88 (136d) - Neighbor Advertisement.<br>0x89 (137d) - Redirect<br>0x82 (130d) - MLD Query<br>0x83 (131d) - MLDv1 Report<br>0x84 (132d) - MLD Done<br>0x8F (143d) - MLDv2 Report<br>This bit is ignored if <i>RCV_EN</i> is cleared. |
|      | 13    | Configure DHCP port 44h Filter (DHCP server packets) | Automatically configure DHCP port 44 filter to BMC. If this bit is set, broadcast packets matching this port are forwarded. Otherwise, this port is not added to the broadcast filtering option.<br>This bit is ignored if <i>RCV_EN</i> is cleared or in IPv6 mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|      | 15:14 | Reserved                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|      | 24:18 | Reserved                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

### 11.5.11.1.8 Clear all Filters Command

The Clear all Filters command is a single fragment command capable of clearing all the receive filters currently programmed for manageability traffic.

| Function          | Command | Byte Count | Data |
|-------------------|---------|------------|------|
| Clear all Filters | 0xC3    | 1          | 0x00 |

### 11.5.11.1.9 Set Thermal Sensor Configuration

This command sets the thermal sensor configuration for threshold *Index* in direction *Direction*, where the threshold is measured in “unit types”, and the *Actions* field describes the actions to activate upon crossing of the threshold in the requested direction according to [Table 11-39](#).

Direction is encoded as follows:

- 0 = High Going
- 1 = Low Going

| Function                         | Command | Byte Count | Data             |       |           |           |                      |                     |            |
|----------------------------------|---------|------------|------------------|-------|-----------|-----------|----------------------|---------------------|------------|
|                                  |         |            | 1                | 2     | 3         | 4:5       | 6:9                  | 10:13               | 14         |
| Set Thermal Sensor Configuration | 0xCB    | 14         | Sub Opcode (0x1) | Index | Direction | Threshold | Actions “Going High” | Actions “Going Low” | Hysteresis |

### 11.5.11.1.10 Perform Thermal Sensor Action

This command executes actions immediately.

The *Actions* field describes the actions to activate according to [Table 11-39](#).

| Function                      | Command | Byte Count | Data 1           | Data 2:5 |
|-------------------------------|---------|------------|------------------|----------|
| Perform Thermal Sensor Action | 0xCB    | 5          | Sub Opcode (0x2) | Actions  |

### 11.5.11.2 Read SMBus Transactions

This section details the pass-through read transactions that the BMC can send to the X550 over SMBus.

SMBus read transactions lists the different SMBus read transactions supported by the X550. All the read transactions are compatible with SMBus read block protocol format.

**Table 11-14. SMBus Read Transactions**

| TCO Command                | Transaction | Write Command <sup>1</sup> | Read Command         | Opcode                                                  | Fragments | Page                |
|----------------------------|-------------|----------------------------|----------------------|---------------------------------------------------------|-----------|---------------------|
| Receive TCO Packet         | Block Read  | N/A                        | 0xD0 or 0xC0         | First: 0x90<br>Middle: 0x10<br>Last <sup>2</sup> : 0x50 | Multiple  | <a href="#">881</a> |
| Read Status                | Block Read  | N/A                        | 0xD0 or 0xC0 or 0xDE | Single: 0xDD                                            | Single    | <a href="#">883</a> |
| Get System MAC Address     | Block Read  | N/A                        | 0xD4                 | Single: 0xD4                                            | Single    | <a href="#">885</a> |
| Read Management Parameters | Block Read  | 0xC1                       | 0xD1                 | Single: 0xD1                                            | Single    | <a href="#">885</a> |

**Table 11-14. SMBus Read Transactions (Continued)**

| TCO Command                           | Transaction | Write Command <sup>1</sup> | Read Command     | Opcode       | Fragments | Page                |
|---------------------------------------|-------------|----------------------------|------------------|--------------|-----------|---------------------|
| Read Management RCV Filter Parameters | Block Read  | 0xCC                       | 0xCD             | Single: 0xCD | Single    | <a href="#">886</a> |
| Get Controller Information            | Block Read  | 0xD5                       | 0xD5             | Single: 0xD5 | Single    | <a href="#">888</a> |
| Get Common filters                    | Block Read  | 0xD3                       | 0xD3             | Single: 0xD3 | Single    | <a href="#">889</a> |
| Read Receive Enable Configuration     | Block Read  | N/A                        | 0xDA             | Single: 0xDA | Single    | <a href="#">890</a> |
| Get Thermal Sensor Capabilities       | Block Read  | 0xCB (index = 0)           | 0xDB (index = 0) | Single: 0xDB | Single    | <a href="#">890</a> |
| Get Thermal Sensor Configuration      | Block Read  | 0xCB (index = 1)           | 0xDB (index = 1) | Single: 0xDB | Single    | <a href="#">891</a> |
| Get Thermal Sensor Status             | Block Read  | 0xCB (index = 2)           | 0xDB (index = 2) | Single: 0xDB | Single    | <a href="#">892</a> |

1. In some commands, a preliminary write command is sent to ask the firmware to prepare the data for the upcoming read command. This column describes the opcode used for the write command.
2. The last fragment of the receive packet is the packet status.

0xC0 or 0xD0 commands are used for more than one payload. If BMC issues these read commands, and the X550 has no pending data to transfer, it always returns as default opcode 0xDD with the X550 status and does not NACK the transaction.

If an SMBus quick read command is received, it is handled as a X550 Request Status command (See [Section 11.5.11.1.2](#) for details).

### 11.5.11.2.1 Receive TCO LAN Packet Transaction

The BMC uses this command to read packets received on the LAN and its status. When the X550 has a packet to deliver to the BMC, it asserts the SMBus notification for the BMC to read the data (or direct receive). Upon receiving notification of the arrival of a LAN receive packet, the BMC begins issuing a Receive TCO packet command using the block read protocol.

A packet can be transmitted to the BMC in at least two fragments (at least one for the packet data and one for the packet status). As a result, BMC should follow the *F* and *L* bit of the opcode.

The opcode can have these values:

- 0x90 — First Fragment
- 0x10 — Middle Fragment
- 0x50 — Indicates the last fragment of the packet, which contains packet status.

If a notification timeout is defined (in the NVM - [Section 6.5.4.3](#)) and the BMC does not finish reading the whole packet within the timeout period, since the packet has arrived, the packet is silently discarded. The time spent in ARA cycle or in reading the packet is not counted by the timeout counter.

Following is the receive TCO packet format and the data format returned from the X550.

| Function           | Command      |
|--------------------|--------------|
| Receive TCO Packet | 0xC0 or 0xD0 |

| Function                    | Byte Count | Data 1 (Opcode) | Data 2                                    | ... | Data N           |
|-----------------------------|------------|-----------------|-------------------------------------------|-----|------------------|
| Receive TCO First Fragment  | N          | 0x90            | Packet Data Byte                          | ... | Packet Data Byte |
| Receive TCO Middle Fragment |            | 0x10            |                                           |     |                  |
| Receive TCO Last Fragment   | 9 (0x9)    | 0x50            | See <a href="#">Section 11.5.11.2.1.1</a> |     |                  |

#### 11.5.11.2.1.1 Receive TCO LAN Status Payload Transaction

This transaction is the last transaction that the X550 issues when a packet received from the LAN is transferred to the BMC. The transaction contains the status of the received packet.

The format of the status transaction is as follows:

| Function                | Byte Count | Data 1 (Opcode) | Data 2 – Data 17 (Status Data) |
|-------------------------|------------|-----------------|--------------------------------|
| Receive TCO Long Status | 9 (0x9)    | 0x50            | See Below                      |

The status is 8 bytes where byte 0 (bits 7:0) is set in Data 2 of the status and byte 7 in Data 9 of the status. [Table 11-15](#) lists the content of the status data.

**Table 11-15. TCO LAN Packet Status Data**

| Name          | Bit(s) | Description                                                                               |
|---------------|--------|-------------------------------------------------------------------------------------------|
| Packet Length | 13:0   | Packet length including CRC, only 14 LSB bits.                                            |
| Reserved      | 15:14  | Reserved.                                                                                 |
| Packet status | 31:16  | See <a href="#">Table 11-16</a> .                                                         |
| VLAN          | 47:32  | The two bytes of the VLAN header tag.                                                     |
| MNG status    | 63:48  | See <a href="#">Table 11-17</a> . This field should be ignored if Receive is not enabled. |

**Table 11-16. Packet Status Info**

| Field        | Bit(s) | Description                                                                                                  |
|--------------|--------|--------------------------------------------------------------------------------------------------------------|
| CRC stripped | 0      | Insertion of CRC is needed.                                                                                  |
| VP           | 1      | VLAN Stripped (indicates if the VLAN is part of the packet, or was removed).                                 |
| LAN#         | 3:2    | Indicates the source port of the packet:<br>00b = Port 0<br>01b = Port 1<br>10b = Reserved<br>11b = Reserved |
| Reserved     | 15:4   | Reserved.                                                                                                    |

**Table 11-17. MNG Status**

| Name                       | Bits | Description                                                                                                                        |
|----------------------------|------|------------------------------------------------------------------------------------------------------------------------------------|
| Pass MNG VLAN Filter Index | 2:0  | Indicates which of the VLAN filters match the packet.                                                                              |
| MNG VLAN Address Match     | 3    | Set when the MNG packet matches one of the MNG VLAN filters.                                                                       |
| Decision Filter index      | 7:4  | Indicates which of the decision filters match the packet.<br>Allows for up to 16 filters, although only 8 are currently supported. |
| Decision Filter match      | 8    | Set when there is a match to one of the Decision filters.                                                                          |
| Reserved                   | 15:9 | Reserved.                                                                                                                          |

### 11.5.11.2.2 Read Status Command

The BMC should use this command after receiving a notification from the X550 (such as SMBus Alert). The X550 also sends a notification to the BMC in either of the following two cases:

- The BMC asserts a request for reading the status.
- The X550 detects a change in one of the Status Data 1 bits (and was set to send status to the BMC on status change) in the Receive Enable command.

**Note:** Commands 0xC0/0xD0 are for backward compatibility and can be used for other payloads. The X550 defines these commands in the opcode as well as which payload this transaction is. When the 0XDE command is set, the X550 always returns opcode 0XDD with the X550 status. The BMC reads the event causing the notification, using the Read Status command as follows.

The X550 response to one of the commands (0xC0 or 0xD0) in a given time as defined in the *SMBus Notification Timeout and Flags* word in the NVM.

| Function    | Command              |
|-------------|----------------------|
| Read Status | 0XC0 or 0XD0 or 0XDE |

| Function                   | Byte Count | Data 1<br>(Opcode) | Data 2<br>(Status Data 1) | Data 3<br>(Status Data 2) |
|----------------------------|------------|--------------------|---------------------------|---------------------------|
| Receive TCO Partial Status | 3          | 0XDD               | See Below                 |                           |

This command can also be executed using the I<sup>2</sup>C quick read format as follows:

| 1     | 7             | 1  | 1   | 8          | 1   | 8             | 1   | 8             | 1   | 1    |
|-------|---------------|----|-----|------------|-----|---------------|-----|---------------|-----|------|
| Start | Slave Address | Rd | Ack | Byte Count | Ack | Status Data 1 | Ack | Status Data 2 | Ack | Stop |
|       |               | 1  | 0   | 0000 0002  | 0   |               | 0   |               | 1   |      |

Table 11-18 lists the status data byte 1 parameters.

**Table 11-18. Status Data Byte 1**

| Bit | Name                      | Description                                                                                                                                                          |
|-----|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1:0 | Power State               | 00b = Dr state<br>01b = D0u state<br>10b = D0 state<br>11b = D3 state                                                                                                |
| 2   | Reserved                  |                                                                                                                                                                      |
| 3   | Initialization Indication | 0b = An NVM reload event has not occurred since the last Read Status cycle.<br>1b = An NVM reload event has occurred since the last Read Status cycle <sup>1</sup> . |
| 4   | PHY Link Forced Up        | Contains the value of the <i>PHY_Link_Up</i> bit. When set, indicates that the PHY link is configured to keep the link up.                                           |
| 5   | Link Status Indication    | 0b = LAN link down.<br>1b = LAN link up.                                                                                                                             |
| 6   | TCO Command Aborted       | 0b = A TCO command abort event did not occur since the last read status cycle.<br>1b = A TCO command abort event occurred since the last read status cycle.          |
| 7   | LAN Port                  | LAN port. Defines the port that sent status.                                                                                                                         |

1. This indication is asserted when the X550 manageability block reloads the NVM and its internal database is updated to the NVM default values. This is an indication that the external BMC should reconfigure the X550, if other values other than the NVM default should be configured.

Status data byte 2 is used by the BMC to indicate whether the LAN device driver is alive and running, and for thermal events.

The LAN device driver valid indication is a bit set by the LAN device driver during initialization; the bit is cleared when the LAN device driver enters a Dx state or is cleared by the hardware on a PCI reset.

Table 11-19 lists status data byte 2.

**Table 11-19. Status Data Byte 2**

| Bit | Name                    | Description                                                |
|-----|-------------------------|------------------------------------------------------------|
| 0   | Thermal Sensor event    | 0b = No thermal event<br>1b = Thermal event asserted.      |
| 2:1 | Reserved                | Reserved.                                                  |
| 3   | Driver Valid Indication | 0b = LAN driver is not alive.<br>1b = LAN driver is alive. |
| 5:4 | Reserved                | Reserved.                                                  |
| 6   | Configuration Change    | 0 = No change.<br>1 = Number of enabled ports changed.     |
| 7   | Reserved                | Reserved.                                                  |

Table 11-20 lists the possible values of bits 2 and 1 and what the BMC can assume from the bits.

**Table 11-20. Status Data Byte 2 (Bits 2 and 1)**

| Previous   | Current | Description                                                                                                      |
|------------|---------|------------------------------------------------------------------------------------------------------------------|
| Don't Care | 00b     | Interrupt is not pending (OK).                                                                                   |
| 00b        | 01b     | New interrupt is asserted (OK).                                                                                  |
| 10b        | 01b     | New interrupt is asserted (OK).                                                                                  |
| 11b        | 01b     | Interrupt is waiting for reading (OK).                                                                           |
| 01b        | 01b     | Interrupt is waiting for reading by the driver for more than one read cycle (not OK). Possible drive hang state. |
| Don't Care | 11b     | Previous interrupt was read and current interrupt is pending (OK).                                               |
| Don't Care | 10b     | Interrupt is not pending (OK).                                                                                   |

BMC reads should consider the time it takes for the LAN device driver to deal with the interrupt (in  $\mu$ s). Note that excessive reads by the BMC can give false indications.

### 11.5.11.2.3 Get System MAC Address

The Get System MAC Address returns the system MAC Address over to the SMBus. This command is a single-fragment Read Block transaction that returns the following the MAC Address configured in RAL0, RAH0 registers.

Get system MAC Address format:

| Function               | Command |
|------------------------|---------|
| Get system MAC Address | 0xD4    |

Data returned from the X550:

| Function               | Byte Count | Data 1 (Opcode) | Data 2          | ... | Data 7          |
|------------------------|------------|-----------------|-----------------|-----|-----------------|
| Get system MAC Address | 7          | 0xD4            | MAC Address MSB | ... | MAC Address LSB |

### 11.5.11.2.4 Read Management Parameters

To read the management parameters the BMC should execute two SMBus transactions. The first transaction is a block write that sets the parameter that the BMC wants to read. The second transaction is block read that reads the parameter.

Block write transaction:

| Function                   | Command | Byte Count | Data 1           |
|----------------------------|---------|------------|------------------|
| Management control request | 0xC1    | 1          | Parameter number |

Following the block write the BMC should issue a block read that reads the parameter that was set in the Block Write command:

| Function                  | Command |
|---------------------------|---------|
| Read management parameter | 0xD1    |

Data returned:

| Function                  | Byte Count | Data 1 (Opcode) | Data 2           | Data 3              | ... | Data N |
|---------------------------|------------|-----------------|------------------|---------------------|-----|--------|
| Read management parameter | N          | 0xD1            | Parameter number | Parameter dependent |     |        |

The returned data is in the same format of the BMC command.

The returned data is as follows:

| Parameter               | #    | Parameter Data                                                                                                                                                                                                                                                                                          |
|-------------------------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Keep PHY Link Up        | 0x00 | A single byte parameter.<br>Data 2:<br>Bit [0] = Set to indicate that the PHY link for this port should be kept up. When set, sets the <i>keep_PHY_link_up</i> bit. When cleared, clears the <i>keep_PHY_link_up</i> bit.<br>Bit [7:1] = Reserved.                                                      |
| Wrong parameter request | 0xFE | Returned by the X550 only. This parameter is returned on read transaction, if in the previous read command the BMC sets a parameter that is not supported by the X550.                                                                                                                                  |
| The X550 is not ready   | 0xFF | Returned by the X550 only, on read parameters command when the data that should have been read is not ready. This parameter has no data. The BMC should retry the read transaction. This value is also returned if the byte count is illegal or if the read command is not preceded by a write command. |

The parameter that is returned might not be the parameter requested by the BMC. The BMC should verify the parameter number (default parameter to be returned is 0x1).

If the parameter number is 0xFF, it means that the data that was requested from the X550 is not ready yet, or that the adequate write command was not given. The BMC should retry the read transaction or send the write transaction.

It is responsibility of the BMC to follow the procedure previously defined. When the BMC sends a Block Read command (as previously described) that is not preceded by a Block Write command with *bytecount*=1, the X550 sets the parameter number in the read block transaction to be 0xFF.

### 11.5.11.2.5 Read Management Receive Filter Parameters

To read the management receive filter parameters, the BMC should execute two SMBus transactions. The first transaction is a block write that sets the parameter that the BMC wants to read. The second transaction is block read that read the parameter.

Block write transaction:

| Function                         | Command | Byte Count | Data 1           | Data 2         |
|----------------------------------|---------|------------|------------------|----------------|
| Update MNG RCV filter parameters | 0xCC    | 1 or 2     | Parameter number | Parameter data |

The different parameters supported for this command are the same as the parameters supported for update Management receive filter parameters.

Following the block write the BMC should issue a block read that reads the parameter that was set in the Block Write command:

| Function                          | Command |
|-----------------------------------|---------|
| Request MNG RCV filter parameters | 0xCD    |

Data returned from the X550:

| Function                       | Byte Count | Data 1 (Opcode) | Data 2           | Data 3              | ... | Data N |
|--------------------------------|------------|-----------------|------------------|---------------------|-----|--------|
| Read MNG RCV filter parameters | N          | 0xCD            | Parameter number | Parameter dependent |     |        |

The parameter that is returned might not be the parameter requested by the BMC. The BMC should verify the parameter number (default parameter to be returned is 0x1).

If the parameter number is 0xFF, it means that the data that was requested from the X550 is not ready yet, or that the adequate write command was not given. The BMC should retry the read transaction or send the write transaction.

It is BMC responsibility to follow the procedure previously defined. When the BMC sends a Block Read command (as previously described) that is not preceded by a Block Write command with bytecount=1, the X550 sets the parameter number in the read block transaction to be 0xFF.

| Parameter                          | #    | Parameter Data                                                                                                                                                                                                                                                  |
|------------------------------------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Filters Enable                     | 0x01 | None.                                                                                                                                                                                                                                                           |
| MNGONLY Configuration              | 0x0F | None.                                                                                                                                                                                                                                                           |

| EtherType Filters                  | 0x67 | 1 byte to define EtherType filters (METF)<br>Data 2 — METF filter index (valid values are 0 - 3)                                                                                                                                                                |
| Extended Decision Filter           | 0x68 | 1 byte to define the extended decisions filters (MDEF_EXT & MDEF)<br>Data 2 — MDEF filter index (valid values are 0 - 5)                                                                                                                                        |
| Wrong parameter request            | 0xFE | Returned by the X550 only. This parameter is returned on read transaction, if in the previous read command the BMC sets a parameter that is not supported by the X550.                                                                                          |
| The X550 is not ready              | 0xFF | Returned by the X550 only, on read parameters command when the data that should have been read is not ready. This parameter has no data.<br>This value is also returned if the byte count is illegal or if the read command is not preceded by a write command. |

### 11.5.11.2.6 Get Controller Information Command

The BMC uses this command to get the controller identification. Each parameter is returned using a different opcode

To read the controller information, the BMC should execute two SMBus transactions. The first transaction is a block write that sets the parameter that the BMC wants to read. The second transaction is block read that read the parameter.

Block write transaction:

| Function                   | Command | Byte Count | Data 1 (Opcode)  |
|----------------------------|---------|------------|------------------|
| Get Controller Information | 0xD5    | 1          | Parameter number |

Following the block write the BMC should issue a block read that reads the parameter that was set in the Block Write command:

| Function                   | Command |
|----------------------------|---------|
| Get Controller Information | 0xD5    |

Data returned from the X550:

| Function                   | Command | Byte Count      | Data 2 (Opcode) | Data 3 -n                                    |
|----------------------------|---------|-----------------|-----------------|----------------------------------------------|
| Get Controller Information | 0xD5    | Per Table 11-21 | Per Table 11-21 | See Table 11-21 for the data for each opcode |

**Table 11-21. Get Controller Information Data**

| Opcode | Byte Count | Description                                                      | Notes                                                                                                                                                                                                                                                                                                                                                                                             |
|--------|------------|------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| 0x17   | 6          | Data 6:3: Firmware Mini Loader Internal version                  |                                                                                                                                                                                                                                                                                                                                                                                                   |
| 0xFE   | 2          | Wrong parameter request                                          | Returned by the X550 only. This parameter is returned on read transaction, if in the previous read command the BMC sets a parameter that is not supported by the X550.                                                                                                                                                                                                                            |
| 0xFF   | 2          | The X550 is not ready                                            | Returned by the X550 only, on read parameters command when the data that should have been read is not ready. This parameter has no data. The BMC should retry the read transaction.<br>This value is also returned if the byte count is illegal or if the read command is not preceded by a write command.<br>This value is returned also if opcode 0x00 is received while device is in Dr state. |

### 11.5.11.2.7 Get Common Filters Command

The BMC uses this command to get the common filters setting. This data can be configured when using Set Common Filters command. The first transaction is a block write that alerts that the BMC wants to read the filters configuration. The second transaction is block read that read the configuration.

Block write transaction:

| Function           | Command | Byte count | Data |
|--------------------|---------|------------|------|
| Get Common Filters | 0xD3    | 1          | 0x00 |

Following the block write the BMC should issue a block read that reads the filter settings:

| Function           | Command |
|--------------------|---------|
| Get Common filters | 0xD3    |

Data returned from the X550:

#### IPv4 Format:

| Function           | Command | Byte Count | Data |                                                    |             |                   |                     |                  |              |
|--------------------|---------|------------|------|----------------------------------------------------|-------------|-------------------|---------------------|------------------|--------------|
|                    |         |            | 1    | 2:4                                                | 5:10        | 11                | 12                  | 13               | 14:17        |
| Get Common Filters | 0xD3    | 18         | 0    | Receive Control (See <a href="#">Table 11-13</a> ) | MAC Address | BMC Alert Address | Interface Data Byte | Alert Value Byte | IPv4 Address |

#### IPv6 Format:

| Function           | Command | Byte Count | Data |                                                    |             |                   |                     |                  |              |
|--------------------|---------|------------|------|----------------------------------------------------|-------------|-------------------|---------------------|------------------|--------------|
|                    |         |            | 1    | 2:4                                                | 5:10        | 11                | 12                  | 13               | 14:29        |
| Get Common Filters | 0xD3    | 30         | 0    | Receive Control (see <a href="#">Table 11-13</a> ) | MAC Address | BMC Alert Address | Interface Data Byte | Alert Value Byte | IPv6 Address |

If case of error the following answers may be returned:

| Function           | Command | Byte Count | Data 1 |
|--------------------|---------|------------|--------|
| Get Common Filters | 0xD3    | 1          | 0xFF   |

This response is by the X550, on read common filter command when the data that should have been read is not ready. This parameter has no data. The BMC should retry the read transaction.

This value is also returned if the byte count is illegal, if the read command is not preceded by a write command, or if the filters were not previously configured with a Set Common Filters command ([Section 11.5.11.1.7](#)).

### 11.5.11.2.8 Read Receive Enable Configuration

The BMC uses this command to read the receive configuration data. This data can be configured when using Receive Enable command or through the NVM.

Read Receive Enable Configuration command format (SMBus Read Block) is as follows:

| Function            | Command |
|---------------------|---------|
| Read Receive Enable | 0xDA    |

Data returned from the X550:

| Function            | Byte Count | Data       |                      |              |     |              |             |     |             |                |               |                  |
|---------------------|------------|------------|----------------------|--------------|-----|--------------|-------------|-----|-------------|----------------|---------------|------------------|
|                     |            | 1 (Opcode) | 2                    | 3            | ... | 8            | 9           | ... | 12          | 13             | 14            | 15               |
| Read Receive Enable | 15 (0x0F)  | 0xDA       | Receive Control Byte | MAC Addr MSB | ... | MAC Addr LSB | IP Addr MSB | ... | IP Addr LSB | BMC SMBus Addr | I/F Data Byte | Alert Value Byte |

The detailed description of each field is specified in the receive enable command description in [Section 11.5.11.1.3](#).

### 11.5.11.2.9 Get Thermal Sensor Capabilities Command

The BMC can use this function to read the thermal sensor capabilities. It uses a write command to set the needed index and then a read block command to read the data.

The write command is:

| Function                         | Command | Byte Count | Sub Opcode |
|----------------------------------|---------|------------|------------|
| Get Thermal Capabilities Request | 0xCB    | 1          | 0x0        |

The read command is:

| Function                         | Command |
|----------------------------------|---------|
| Get Thermal Capabilities Request | 0xDB    |

The data returned from the X550 is:

| Function                        | Byte Count | Data 1 (Opcode) | Data 2 (Sub Opcode) | Data 3 (Version) | Data 4 (Unit Types)             | Data 5:6 (Number of Thresholds) | Data 7 (Accuracy) |
|---------------------------------|------------|-----------------|---------------------|------------------|---------------------------------|---------------------------------|-------------------|
| Get Thermal Sensor Capabilities | 26         | 0xDB            | 0x0                 | 1                | See <a href="#">Table 11-40</a> | See below                       |                   |

| Data 8 (Hysteresis) | Data 9 (M) | Data 10 (B) | Data 11 (K1) | Data 12 (K2) | Data 13:16 (Valid High Going Actions) | Data 17:20 (Valid Low Going Actions) | Data 21:24 (Valid Immediate Actions) | Data 25:26 (Tjunction Max) |
|---------------------|------------|-------------|--------------|--------------|---------------------------------------|--------------------------------------|--------------------------------------|----------------------------|
| See below           | See below  |             |              |              | See <a href="#">Table 11-39</a>       | See <a href="#">Table 11-39</a>      | See <a href="#">Table 11-39</a>      | See below                  |

- Version should always be 1.
- Unit Types describes the unit types measured according to the encoding in [Table 11-40](#).
- Accuracy describes the accuracy of the reported measurements as follows:
  - 7:4: Max deviation of actual value above measurement in “unit types”.
  - 3:0: Max deviation of actual value below measurement in “unit types”.
- Max hysteresis — Defines the max hysteresis value allowed in the implementation. A value of zero means hysteresis is not supported.
- Number of thresholds describes the number of up and down thresholds as follows:
  - 15:12: Reserved
  - 11:8: Max Number of mixed thresholds.
  - 7:4: Max number of up thresholds.
  - 3:0: Max number of down thresholds.
- Valid Actions “High Going” thresholds — Describes the actions that can be activated by the device as described in [Table 11-39](#) when a high going threshold is crossed or the upper hysteresis of a “High Going” Threshold is crossed.
- Valid Actions “Low going” thresholds — Describes the actions that can be activated by the device as described in [Table 11-39](#) when a low going threshold is crossed or the lower hysteresis of a “Low Going” Threshold is crossed.
- Valid Actions “Immediate” — Describes the actions that can be activated by the device as described in [Table 11-39](#) using a “Perform Thermal Sensor Action” command.
- M, B, K1, K2 — Parameters used to translate the raw data read to a meaningful value according to the following formula:
 
$$Y = (MX + (B * 10^{K1})) * 10^{K2}$$
 where X is the measured value, and Y is the value presented to the user.
 

**Note:** This formula is compliant with the definition of section 36.3 “Sensor Reading Conversion Formula” in IPMI 2.0
- Tjunction Max - The maximal junction temperature supported (105 °C)

#### 11.5.11.2.10 Get Thermal Sensor Configuration Command

The BMC can use this function to read the thermal sensor configuration for a given threshold. It uses a write command to set the needed index and then a read block command to read the data.

The write command is:

| Function                          | Command | Byte Count | Sub Opcode | Data 1 |
|-----------------------------------|---------|------------|------------|--------|
| Get Thermal Configuration Request | 0xCB    | 2          | 0x1        | Index  |

The read command is:

| Function                          | Command |
|-----------------------------------|---------|
| Get Thermal Configuration Request | 0xDB    |

The data returned from the X550 is:

| Function                         | Byte Count | Data 1 (Opcode) | Data 2 (Sub Opcode) | Data 3 (Index) | Data 4:5 (Threshold)     | Data 6:9 (Action "Going High")                                     |
|----------------------------------|------------|-----------------|---------------------|----------------|--------------------------|--------------------------------------------------------------------|
| Get Thermal Sensor Configuration | 15         | 0xDB            | 0x1                 | Index          | The programmed threshold | The programmed actions as described in <a href="#">Table 11-39</a> |

| Data 10:13 (Action "Going Low")                                    | Data 14 (Direction) | Data 15 (Hysteresis) |
|--------------------------------------------------------------------|---------------------|----------------------|
| The programmed actions as described in <a href="#">Table 11-39</a> | See below           | See below            |

The threshold and the Hysteresis are measured in "unit types".

**Note:** If the Max hysteresis reported in the Thermal Sensor capabilities is zero, the Hysteresis value is ignored.

The *Actions Going High* field describes the actions to activate upon crossing of the threshold for "Going High" thresholds or when crossing the hysteresis for "Going Low" thresholds according to [Table 11-39](#).

The *Actions Going Low* field describes the actions to activate upon crossing of the threshold for "Going Low" thresholds or when crossing the hysteresis for "Going High" thresholds according to [Table 11-39](#).

Direction is encoded as follows:

0 = High Going

1 = Low Going

If the opcode is 0xFF, it means that the data that was requested from the X550 is not ready yet, or that the adequate write command was not given. The BMC should retry the read transaction or send the write transaction.

#### 11.5.11.2.11 Get Thermal Sensor Status Command

The BMC can use this function to read the thermal sensor status. It uses a write command to set the needed index and then a read block command to read the data.

The write command is:

| Function                          | Command | Byte Count | Sub Opcode |
|-----------------------------------|---------|------------|------------|
| Get Thermal Sensor Status Request | 0xCB    | 1          | 0x2        |

The read command is:

| Function                          | Command |
|-----------------------------------|---------|
| Get Thermal Sensor Status Request | 0xDB    |

The data returned from the X550 is:

| Function                  | Byte Count | Data 1 (Opcode) | Data 2 (Sub Opcode) | Data 3:4 (Measured Value)          | Data 5:8 (Active Actions)                                                | Data 9:10 (Threshold Cross Event) |
|---------------------------|------------|-----------------|---------------------|------------------------------------|--------------------------------------------------------------------------|-----------------------------------|
| Get Thermal Sensor Status | 10         | 0xDB            | 0x2                 | The value measured in "unit types" | The currently active actions as described in <a href="#">Table 11-39</a> | See below                         |

"Threshold cross events" is a bitmap that describes which events were crossed since the last read of the status or since the activation of the thermal sensor (the latest of the two). Bit 'n' in the bitmap represent threshold index 'n' as configured in the Set Thermal Sensor Configuration command ([Section 11.5.11.1.9](#))

If the opcode is 0xFF, it means that the data that was requested from the X550 is not ready yet, or that the adequate write command was not given. The BMC should retry the read transaction or send the write transaction.

## 11.5.12 Example Configuration Steps

This section provides sample configuration settings for common filtering configurations. Three examples are presented. The examples are in pseudo code format, with the name of the SMBus command followed by the parameters for that command and an explanation.

### 11.5.12.1 Example 1 - Shared MAC, RMCP Only Ports

This example is the most basic configuration. The MAC Address filtering is shared with the host operating system and only traffic directed the RMCP ports (26Fh & 298h) is filtered. For this example, the BMC must issue gratuitous ARPs because no filter is enabled to pass ARP requests to the BMC.

#### 11.5.12.1.1 Example 1 Pseudo Code

##### Step 1: Disable existing filtering

```
Receive Enable[00]
```

Utilizing the simple form of the Receive Enable command, this prevents any packets from reaching the BMC by disabling filtering:

Receive Enable Control 00h:

- Bit 0 [0] – Disable Receiving of packets

##### Step 2: Configure MDEF[0]

```
Update Manageability Filter Parameters [68, 0, C0000000, 00000000]
```

Use the Update Manageability Filter Parameters command to update Decision Filters (MDEF) (parameter 68h). This updates MDEF[0], as indicated by the 2nd parameter (0).

MDEF[0] value of C0000000h:

- Bit 30 [1] – port 298h
- Bit 31 [1] – port 26Fh

MDEF\_EXT[0] value of 00000000h:

### Step 3: Configure *MNGONLY*

Update Manageability Filter Parameters [F, 0, 00000001]

Use the Update Manageability Filter Parameters command to update Manageability Only (*MNGONLY*) (parameter 0xF) so that port 298h and 26Fh would not be sent to the host.

- Bit [0] - *MDEF[0]* is exclusive to the BMC.

### Step 4: - Enable Filtering

Receive Enable [05]

Using the simple form of the Receive Enable command:

Receive Enable Control 05h:

- Bit 0 [1] – Enable Receiving of packets
- Bit 2 [1] – Enable status reporting (such as link lost)
- Bit 5:4 [00] – Notification method = SMB Alert
- Bit 7 [0] – Use shared MAC

The resulting MDEF filters are as follows:

**Table 11-22. Example 1 MDEF Results**

|                         |     | Manageability Decision Filter (MDEF) |   |   |   |   |   |   |   |
|-------------------------|-----|--------------------------------------|---|---|---|---|---|---|---|
| Filter                  |     | 0                                    | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| L2 Unicast Address[3:0] | AND |                                      |   |   |   |   |   |   |   |
| Broadcast               | AND |                                      |   |   |   |   |   |   |   |
| Manageability VLAN[7:0] | AND |                                      |   |   |   |   |   |   |   |
| IPv6 Address[3:0]       | AND |                                      |   |   |   |   |   |   |   |
| IPv4 Address[3:0]       | AND |                                      |   |   |   |   |   |   |   |
| L2 Unicast Address[3:0] | OR  |                                      |   |   |   |   |   |   |   |
| Broadcast               | OR  |                                      |   |   |   |   |   |   |   |
| Multicast               | AND |                                      |   |   |   |   |   |   |   |
| ARP Request             | OR  |                                      |   |   |   |   |   |   |   |
| ARP Response            | OR  |                                      |   |   |   |   |   |   |   |
| Neighbor Discovery      | OR  |                                      |   |   |   |   |   |   |   |
| Port 0x298              | OR  | X                                    |   |   |   |   |   |   |   |
| Port 0x26F              | OR  | X                                    |   |   |   |   |   |   |   |
| Flex Port 7:0           | OR  |                                      |   |   |   |   |   |   |   |
| Flex TCO                | OR  |                                      |   |   |   |   |   |   |   |

### 11.5.12.2 Example 2 - Dedicated MAC, Auto ARP Response and RMCP Port Filtering

This example shows a common configuration; the BMC has a dedicated MAC and IP Address. Automatic ARP responses are enabled as well as RMCP port filtering. By enabling Automatic ARP responses the BMC is not required to send the gratuitous ARPs as it did in Example 1.

For demonstration purposes, the dedicated MAC Address is calculated by reading the System MAC Address and adding 1 to it, assume the System MAC is AABBCDC. The IP Address for this example is 1.2.3.4. Additionally, the XSUM filtering is enabled.

Note that not all Intel Ethernet Controllers support automatic ARP responses, please refer to product specific documentation.

#### 11.5.12.2.1 Example 2 - Pseudo Code

##### Step 1: Disable existing filtering

```
Receive Enable[00]
```

Utilizing the simple form of the Receive Enable command, this prevents any packets from reaching the BMC by disabling filtering:

Receive Enable Control 00h:

- Bit 0 [0] – Disable Receiving of packets

##### Step 2: Read System MAC Address

```
Get System MAC Address []
```

Reads the System MAC Address. Assume returned AABBCDC for this example.

##### Step 3: Configure XSUM Filter

```
Update Manageability Filter Parameters [01, 00800000]
```

Use the Update Manageability Filter Parameters command to update Filters Enable settings (parameter 1). This sets the Manageability Control (MANC) Register.

MANC Register 00800000h:

- Bit 23 [1] - XSUM Filter enable

Note that some of the following configuration steps manipulate the MANC register indirectly, this command sets all bits except XSUM to 0. It is important to either do this step before the others, or to read the value of the MANC and then write it back with only bit 32 changed. Also note that the XSUM enable bit may differ between Ethernet Controllers, refer to product specific documentation.

##### Step 4: Configure MDEF[0]

```
Update Manageability Filter Parameters [68, 0, C0000000, 00000000]
```

Use the Update Manageability Filter Parameters command to update Decision Filters (MDEF) (parameter 68h). This updates MDEF[0], as indicated by the 2nd parameter (0).

MDEF value of 00000C00h:

- Bit 30 [1] – port 298h
- Bit 31 [1] – port 26Fh

MDEF\_EXT[0] value of 00000000h:

### Step 5: Configure MDEF[1]

Update Manageability Filter Parameters [68, 1, 10000000, 00000000]

Use the Update Manageability Filter Parameters command to update Decision Filters (MDEF) (parameter 61h). This updates MDEF[1], as indicated by the 2<sup>nd</sup> parameter (1).

MDEF value of 10000000:

- Bit 28 [1] – ARP Requests

MDEF\_EXT[1] value of 0000000h:

When Enabling Automatic ARP responses, the ARP requests still go into the manageability filtering system and as such need to be designated as also needing to be sent to the host. For this reason a separate MDEF is created with only ARP request filtering enabled.

Refer to the next step for more details.

### Step 6: Configure Manageability only

Update Manageability Filter Parameters [F, 0, 00000001]

Use the Update Manageability Filter Parameters command to update Manageability Only (MNGONLY) (parameter 0xF) so that port 298h and 26Fh would not be sent to the host.

- Bit [0] - MDEF[0] is exclusive to the BMC.

This allows ARP requests to be passed to both manageability and to the host. Specified separate MDEF filter for ARP requests. If ARP requests had been added to *MDEF[0]* and then *MDEF[0]* specified in Management Only configuration, not only would RMCP traffic (ports 26Fh and 298h) be sent only to the BMC, ARP requests would have also been sent to the BMC only.

### Step 7: Enable Filtering

Receive Enable [8D, AABBCDD, 01020304, 00, 00, 00]

Using the advanced version Receive Enable command, the first parameter:

Receive Enable Control 8Dh:

- Bit 0 [1] – Enable Receiving of packets
- Bit 2 [1] – Enable status reporting (such as link lost)
- Bit 3 [1] – Enable Automatic ARP Responses
- Bit 5:4 [00] – Notification method = SMB Alert
- Bit 7 [1] - Use dedicated MAC

Second parameter is the MAC Address (AABBCDD).

Third Parameter is the IP Address(01020304).

The last three parameters are zero when the notification method is SMB Alert.

The resulting MDEF filters are as follows:

Table 11-23. Example 2 MDEF Results

|                         |     | Manageability Decision Filter (MDEF) |   |   |   |   |   |   |   |
|-------------------------|-----|--------------------------------------|---|---|---|---|---|---|---|
| Filter                  |     | 0                                    | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| L2 Unicast Address[3:0] | AND |                                      |   |   |   |   |   |   |   |
| Broadcast               | AND |                                      |   |   |   |   |   |   |   |
| Manageability VLAN[7:0] | AND |                                      |   |   |   |   |   |   |   |
| IPv6 Address[3:0]       | AND |                                      |   |   |   |   |   |   |   |
| IPv4 Address[3:0]       | AND |                                      |   |   |   |   |   |   |   |
| L2 Unicast Address[3:0] | OR  |                                      |   |   |   |   |   |   |   |
| Broadcast               | OR  |                                      |   |   |   |   |   |   |   |
| Multicast               | AND |                                      |   |   |   |   |   |   |   |
| ARP Request             | OR  |                                      | X |   |   |   |   |   |   |
| ARP Response            | OR  |                                      |   |   |   |   |   |   |   |
| Neighbor Discovery      | OR  |                                      |   |   |   |   |   |   |   |
| Port 0x298              | OR  | X                                    |   |   |   |   |   |   |   |
| Port 0x26F              | OR  | X                                    |   |   |   |   |   |   |   |
| Flex Port 7:0           | OR  |                                      |   |   |   |   |   |   |   |
| Flex TCO                | OR  |                                      |   |   |   |   |   |   |   |

### 11.5.12.3 Example 3 - Dedicated MAC & IP Address

This example provided the BMC with a dedicated MAC and IP Address and allows it to receive ARP requests. The BMC is then responsible for responding to ARP requests.

For demonstration purposes, the dedicated MAC Address is calculated by reading the System MAC Address and adding 1 to it, assume the System MAC is AABBCDCD. The IP Address for this example is 1.2.3.4. For this example, the Receive Enable command is used to configure the MAC Address filter.

For the BMC to be able to receive ARP Requests, it needs to specify a filter for this. That filter must be included in the Manageability To Host filtering so that the host OS may also receive ARP Requests.

#### 11.5.12.3.1 Example 3 - Pseudo Code

##### Step 1: Disable existing filtering

```
Receive Enable[00]
```

Utilizing the simple form of the Receive Enable command, this prevents any packets from reaching the BMC by disabling filtering:

Receive Enable Control 00h:

- Bit 0 [0] – Disable Receiving of packets

##### Step 2: Read System MAC Address

```
Get System MAC Address []
```

Reads the System MAC Address. Assume returned AABBCDCD for this example.

### Step 3: Configure IP Address Filter

Update Manageability Filter Parameters [64, 00, 01020304]

Use the Update Manageability Filter Parameters to configure an IPv4 filter.

The 1st parameter (64h) specifies that we are configuring an IPv4 filter.

The 2nd parameter (00h) indicates which IPv4 filter is being configured, in this case filter 0.

The 3rd parameter is the IP Address – 1.2.3.4.

### Step 4: Configure MAC Address Filter

Update Manageability Filter Parameters [66, 00, AABBCDD]

Use the Update Manageability Filter Parameters to configure a MAC Address filter.

The 1st parameter (66h) specifies that we are configuring a MAC Address filter.

The 2nd parameter (00h) indicates which MAC Address filter is being configured, in this case filter 0.

The 3rd parameter is the MAC Address - AABBCDD

### Step 5: Configure MDEF[0] for IP and MAC Filtering

Update Manageability Filter Parameters [68, 0, 00002001, 00000000]

Use the Update Manageability Filter Parameters command to update Decision Filters (MDEF) (parameter 68h). This updates MDEF[0], as indicated by the 2nd parameter (0).

MDEF value of 00002001:

- Bit 0 [1] – MAC[0] Address Filtering
- Bit 13 [1] – IP[0] Address Filtering

MDEF\_EXT[0] value of 0000000h:

### Step 6: Configure MDEF[1]

Update Manageability Filter Parameters [68, 1, 10000000]

Use the Update Manageability Filter Parameters command to update Decision Filters (MDEF) (parameter 68h). This updates MDEF[1], as indicated by the 2nd parameter (1).

MDEF value of 10000000:

- Bit 28 [1] – ARP Requests

MDEF\_EXT[1] value of 0000000h:

### Step 7: Configure the Management to Host Filter

Update Manageability Filter Parameters [F, 0, 00000001]

Use the Update Manageability Filter Parameters command to update Manageability Only (*MNGONLY*) (parameter 0xF) so that the dedicated MAC/IP traffic would not be sent to the Host. Note that given the host does not program this address in its L2 filtering, this step is not a must, unless the host chooses to work in promiscuous mode.

- Bit [0] - MDEF[0] is exclusive to the BMC.

## Step 8: Enable Filtering

Receive Enable [05]

Using the simple form of the Receive Enable command:

Receive Enable Control 05h:

- Bit 0 [1] – Enable Receiving of packets
- Bit 2 [1] – Enable status reporting (such as link lost)
- Bit 5:4 [00] – Notification method = SMB Alert

The resulting MDEF filters are as follows:

**Table 11-24. Example 3 MDEF Results**

|                         |     | Manageability Decision Filter (MDEF) |   |   |   |   |   |   |   |
|-------------------------|-----|--------------------------------------|---|---|---|---|---|---|---|
| Filter                  |     | 0                                    | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| L2 Unicast Address[3:0] | AND | 0001                                 |   |   |   |   |   |   |   |
| Broadcast               | AND |                                      |   |   |   |   |   |   |   |
| Manageability VLAN[7:0] | AND |                                      |   |   |   |   |   |   |   |
| IPv6 Address[3:0]       | AND |                                      |   |   |   |   |   |   |   |
| IPv4 Address[3:0]       | AND | 0001                                 |   |   |   |   |   |   |   |
| L2 Unicast Address[3:0] | OR  |                                      |   |   |   |   |   |   |   |
| Broadcast               | OR  |                                      |   |   |   |   |   |   |   |
| Multicast               | AND |                                      |   |   |   |   |   |   |   |
| ARP Request             | OR  |                                      | X |   |   |   |   |   |   |
| ARP Response            | OR  |                                      |   |   |   |   |   |   |   |
| Neighbor Discovery      | OR  |                                      |   |   |   |   |   |   |   |
| Port 0x298              | OR  |                                      |   |   |   |   |   |   |   |
| Port 0x26F              | OR  |                                      |   |   |   |   |   |   |   |
| Flex Port 7:0           | OR  |                                      |   |   |   |   |   |   |   |
| Flex TCO                | OR  |                                      |   |   |   |   |   |   |   |

### 11.5.12.4 Example 4 - Dedicated MAC and VLAN Tag

This example shows an alternate configuration; the BMC has a dedicated MAC and IP Address, along with a VLAN tag of 32h is required for traffic to be sent to the BMC. This means that all traffic with VLAN a matching tag is sent to the BMC.

For demonstration purposes, the dedicated MAC Address is calculated by reading the System MAC Address and adding 1 to it, assume the System MAC is AABBCDC. The IP Address for this example is 1.2.3.4 and the VLAN tag is 0032h.

Additionally, the XSUM filtering is enabled.

#### 11.5.12.4.1 Example 4 - Pseudo Code

##### Step 1: Disable existing filtering

```
Receive Enable[00]
```

Utilizing the simple form of the Receive Enable command, this prevents any packets from reaching the BMC by disabling filtering:

Receive Enable Control 00h:

- Bit 0 [0] – Disable Receiving of packets

##### Step 2: - Read System MAC Address

```
Get System MAC Address []
```

Reads the System MAC Address. Assume returned AABBCDC for this example.

##### Step 3: Configure XSUM Filter

```
Update Manageability Filter Parameters [01, 00800000]
```

Use the Update Manageability Filter Parameters command to update Filters Enable settings (parameter 1). This set the Manageability Control (MANC) Register.

MANC Register 00800000h:

- Bit 23 [1] – XSUM Filter enable

Note that some of the following configuration steps manipulate the MANC register indirectly, this command sets all bits except XSUM to 0. It is important to either do this step before the others, or to read the value of the MANC and then write it back with only bit 32 changed. Also note that the XSUM enable bit may differ between Ethernet Controllers, refer to product specific documentation.

##### Step 4: Configure VLAN 0 Filter

```
Update Manageability Filter Parameters [62, 0, 0032]
```

Use the Update Manageability Filter Parameters command to configure VLAN filters. Parameter 62h indicates update to VLAN Filter, the 2nd parameter indicates which VLAN filter (0 in this case), the last parameter is the VLAN ID (0032h).

## Step 5: Configure MDEF[0]

Update Manageability Filter Parameters [68, 0, 00000020, 00000000]

Use the Update Manageability Filter Parameters command to update Decision Filters (MDEF) (parameter 68h). This updates MDEF[0], as indicated by the 2nd parameter (0).

MDEF value of 00000020:

- Bit 5 [1] – VLAN[0] AND

MDEF\_EXT[0] value of 0000000h:

## Step 6: Enable Filtering

Receive Enable [85, AABBCDD, 01020304, 00, 00, 00]

Using the advanced version Receive Enable command, the first parameter:

Receive Enable Control 85h:

- Bit 0 [1] – Enable Receiving of packets
- Bit 2 [1] – Enable status reporting (such as link lost)
- Bit 5:4 [00] – Notification method = SMB Alert
- Bit 7 [1] – Use Dedicated MAC

Second parameter is the MAC Address: AABBCDD.

Third Parameter is the IP Address: 01020304.

The last three parameters are zero when the notification method is SMBus Alert.

The resulting MDEF filters are as follows:

**Table 11-25. Example 4 MDEF Results**

|                         |     | Manageability Decision Filter (MDEF) |   |   |   |   |   |   |      |
|-------------------------|-----|--------------------------------------|---|---|---|---|---|---|------|
| Filter                  |     | 0                                    | 1 | 2 | 3 | 4 | 5 | 6 | 7    |
| L2 Unicast Address[3:0] | AND |                                      |   |   |   |   |   |   | 0001 |
| Broadcast               | AND |                                      |   |   |   |   |   |   |      |
| Manageability VLAN[7:0] | AND | X                                    |   |   |   |   |   |   |      |
| IPv6 Address[3:0]       | AND |                                      |   |   |   |   |   |   |      |
| IPv4 Address[3:0]       | AND |                                      |   |   |   |   |   |   |      |
| L2 Unicast Address[3:0] | OR  |                                      |   |   |   |   |   |   |      |
| Broadcast               | OR  |                                      |   |   |   |   |   |   |      |
| Multicast               | AND |                                      |   |   |   |   |   |   |      |
| ARP Request             | OR  |                                      |   |   |   |   |   |   |      |
| ARP Response            | OR  |                                      |   |   |   |   |   |   |      |
| Neighbor Discovery      | OR  |                                      |   |   |   |   |   |   |      |
| Port 0x298              | OR  |                                      |   |   |   |   |   |   |      |
| Port 0x26F              | OR  |                                      |   |   |   |   |   |   |      |
| Flex Port 7:0           | OR  |                                      |   |   |   |   |   |   |      |
| Flex TCO                | OR  |                                      |   |   |   |   |   |   |      |

## 11.5.13 SMBus Troubleshooting

This section outlines the most common issues found while working with pass-through using the SMBus sideband interface.

### 11.5.13.1 TCO Alert Line Stays Asserted After a Power Cycle

After the X550 resets, all its ports indicates a status change. If the BMC only reads status from one port (slave address), the other one continues to assert the TCO alert line.

Ideally, the BMC should use the ARA transaction (see [Section 11.5.10](#)) to determine which slave asserted the TCO alert. Many customers only wish to use one port for manageability thus using ARA might not be optimal.

An alternate to using ARA is to configure part of the ports to not report status and to set its SMBus timeout period. In this case, the SMBus timeout period determines how long a port asserts the TCO alert line awaiting a status read from a BMC; by default this value is zero (indicates an infinite timeout).

The SMBus configuration section of the NVM has a *SMBus Notification Timeout* (ms) field that can be set to a recommended value of 0xFF (for this issue). Note that this timeout value is for all slave addresses. Along with setting the SMBus Notification Timeout to 0xFF, it is recommended that the other ports be configured in the NVM to disable status alerting. This is accomplished by having the *Enable Status Reporting* bit set to 0b for the desired ports in the LAN configuration section of the NVM.

The third solution for this issue is to have the BMC hard-code the slave addresses to always read from all ports. As with the previous solution, it is recommend that the other ports have status reporting disabled.

### 11.5.13.2 When SMBus Commands are Always NACK'd

There are several reasons why all commands sent to the X550 from a BMC could be NACK'd. The following are most common:

- Invalid NVM Image — The image itself might be invalid or it could be a valid image and is not a pass-through image, as such SMBus connectivity is disabled.
- The BMC is not using the correct SMBus address — Many BMC vendors hard-code the SMBus address(es) into their firmware. If the incorrect values are hard-coded, the X550 does not respond.
  - The SMBus address(es) can be dynamically set using the SMBus ARP mechanism.
- The BMC is using the incorrect SMBus interface — The NVM might be configured to use one physical SMBus port; however, the BMC is physically connected to a different one.
- Bus Interference — The bus connecting the BMC and the X550 might be unstable.

### 11.5.13.3 SMBus Clock Speed is 16.6666 KHz

This can happen when the SMBus connecting the BMC and the X550 is also tied into another device (such as an ICH) that has a maximum clock speed of 16.6666 KHz. The solution is to not connect the SMBus between the X550 and the BMC to this device.

#### 11.5.13.4 A Network Based Host Application is Not Receiving Any Network Packets

Reports have been received about an application not receiving any network packets. The application in question was NFS under Linux. The problem was that the application was using the RMPC/RMCP+ IANA reserved port 0x26F (623) and the system was also configured for a shared MAC and IP Address with the OS and BMC.

The management control to host configuration, in this situation, was setup not to send RMCP traffic to the OS (this is typically the correct configuration). This means that no traffic sent to port 623 was being routed.

The solution in this case is to configure the problematic application NOT to use the reserved port 0x26F.

#### 11.5.13.5 Unable to Transmit Packets from the BMC

If the BMC has been transmitting and receiving data without issue for a period of time, and then begins to receive NACKs from the X550 when it attempts to write a packet, the problem is most likely due to the fact that the buffers internal to the X550 are full of data that has been received from the network but has yet to be read by the BMC.

Being an embedded device, the X550 has limited buffers that are shared for receiving and transmitting data. If a BMC does not keep the incoming data read, the X550 can be filled up. This prevents the BMC from transmitting more data, resulting in NACKs.

If this situation occurs, the recommended solution is to have the BMC issue a Receive Enable command to disable more incoming data, read all the data from the X550, and then use the Receive Enable command to enable incoming data.

#### 11.5.13.6 SMBus Fragment Size

The SMBus specification indicates a maximum SMBus transaction size of 32 bytes. Most of the data passed between the X550 and the BMC over the SMBus is RMCP/RMCP+ traffic, which by its very nature (UDP traffic) is significantly larger than 32 bytes in length. Multiple SMBus transactions may therefore be required to move data from the X550 to the BMC or to send a data from the BMC to the X550.

Recognizing this bottleneck, the X550 handles up to 240 bytes of data in a single transaction. This is a configurable setting in the NVM. The default value in the NVM images is 32, per the SMBus specification. If performance is an issue, increase this size.

During initialization, firmware within the X550 allocates buffers based upon the SMBus fragment size setting within the NVM. The X550 firmware has a finite amount of RAM for its use: the larger the SMBus fragment size, the fewer buffers it can allocate. Because this is true, BMC implementations must take care to send data over the SMBus efficiently.

For example, the X550 firmware has 3 KB of RAM it can use for buffering SMBus fragments. If the SMBus fragment size is 32 bytes, the firmware could allocate 96 buffers of size 32 bytes each. As a result, the BMC could then send a large packet of data (such as KVM) that is 800 bytes in size in 25 fragments of size 32 bytes apiece.

However, this might not be the most efficient way because the BMC must break the 800 bytes of data into 25 fragments and send each one at a time.

If the SMBus fragment size is changed to 240 bytes, the X550 firmware can create 12 buffers of 240 bytes each to receive SMBus fragments. The BMC can now send that same 800 bytes of KVM data in only four fragments, which is much more efficient.

The problem of changing the SMBus fragment size in the NVM is if the BMC does not also reflect this change. If a programmer changes the SMBus fragment size in the X550 to 240 bytes, and then wants to send 800 bytes of KVM data, the BMC can still only send the data in 32 byte fragments. As a result, firmware runs out of memory.

This is because firmware created the 12 buffers of 240 bytes each for fragments; however, the BMC is only sending fragments of size 32 bytes. This results in a memory waste of 208 bytes per fragment. Then when the BMC attempts to send more than 12 fragments in a single transaction, the X550 NACKs the SMBus transaction due to not enough memory to store the KVM data.

In summary, if a programmer increases the size of the SMBus fragment size in the NVM (recommended for efficiency purposes) take care to ensure that the BMC implementation reflects this change and uses that fragment size to its fullest when sending SMBus fragments.

### 11.5.13.7 Losing Link

Normal behavior for the Ethernet Controller when the system powers down or performs a reset is for the link to temporarily go down and then back up again to re-negotiate the link speed. This behavior can have adverse affects on manageability.

For example if there is an active FTP or Serial Over LAN session to the BMC, this connection may be lost. To avoid this possible situation, the BMC can use the Management Control command detailed in [Section 11.5.11.1.5](#) to ensure the link stays active at all times.

This command is available when using the NC-SI sideband interface as well.

Care should be taken with this command. If the driver negotiates the maximum link speed, the link speed remains the same when the system powers down or resets. This may have undesirable power consumption consequences. Currently, when using NC-SI, the BMC can re-negotiate the link speed. That functionality is not available when using the SMBus interface.

### 11.5.13.8 Enable Checksum Filtering

If Checksum filtering is enabled, the BMC does not need to perform the task of checking this checksum for incoming packets. Only packets that have a valid Checksum is passed to the BMC. All others are silently discarded.

This is a way to offload some work from the BMC.

### 11.5.13.9 Still Having Problems?

If problems still exist, contact your field representative. Be prepared to provide the following:

- A SMBus trace if possible
- A dump of the NVM image. This should be taken from the actual X550, rather than the NVM image provided by Intel. Parts of the NVM image are changed after writing (such as the physical NVM size).

## 11.6 NC-SI Pass-Through Interface

The Network Controller Sideband Interface (NC-SI) is a DMTF industry standard protocol for the sideband interface. NC-SI uses a modified version of the industry standard RMII interface for the physical layer as well as defining a new logical layer.

The NC-SI specification supported by the X550 can be found at:

[http://www.dmtf.org/sites/default/files/standards/documents/DSP0222\\_1.0.1.pdf](http://www.dmtf.org/sites/default/files/standards/documents/DSP0222_1.0.1.pdf)

### 11.6.1 Overview

#### 11.6.1.1 Terminology

The terminology in this document is taken from the NC-SI specification.

**Table 11-26. NC-SI Terminology**

| Term                                  | Definition                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Frame Versus Packet                   | Frame is used in reference to Ethernet, whereas packet is used everywhere else.                                                                                                                                                                                                                                                                                                                                                                                       |
| External Network Interface            | The interface of the network controller that provides connectivity to the external network infrastructure (port).                                                                                                                                                                                                                                                                                                                                                     |
| Internal Host Interface               | The interface of the network controller that provides connectivity to the host OS running on the platform.                                                                                                                                                                                                                                                                                                                                                            |
| Management Controller (BMC)           | An intelligent entity comprising of HW/FW/SW, that resides within a platform and is responsible for some or all management functions associated with the platform (BMC, service processor, etc.).                                                                                                                                                                                                                                                                     |
| Network Controller (NC)               | The component within a system that is responsible for providing connectivity to the external Ethernet network world.                                                                                                                                                                                                                                                                                                                                                  |
| Remote Media                          | The capability to allow remote media devices to appear as if they were attached locally to the host.                                                                                                                                                                                                                                                                                                                                                                  |
| Network Controller Sideband Interface | The interface of the network controller that provides connectivity to a management controller. It can be shortened to sideband interface as appropriate in the context.                                                                                                                                                                                                                                                                                               |
| Interface                             | This refers to the entire physical interface, such as both the transmit and receive interface between the management controller and the network controller.                                                                                                                                                                                                                                                                                                           |
| Integrated Controller                 | The term integrated controller refers to a network controller device that supports two or more channels for NC-SI that share a common NC-SI physical interface. For example, a network controller that has two or more physical network ports and a single NC-SI bus connection.                                                                                                                                                                                      |
| Multi-Drop                            | Multi-drop commonly refers to the case where multiple physical communication devices share an electrically common bus and a single device acts as the master of the bus and communicates with multiple slave or target devices. In NC-SI, a management controller serves the role as the master, and the network controllers are the target devices.                                                                                                                  |
| Point-to-Point                        | Point-to-point commonly refers to the case where only two physical communication devices are interconnected via a physical communication medium. The devices might be in a master/slave relationship, or could be peers. In NC-SI, point-to-point operation refers to the situation where only a single management controller and single network controller package are used on the bus in a master/slave relationship where the management controller is the master. |
| Channel                               | The control logic and data paths supporting NC-SI pass-through operation on a single network interface (port). A network controller that has multiple network interface ports can support an equivalent number of NC-SI channels.                                                                                                                                                                                                                                     |

Table 11-26. NC-SI Terminology (Continued)

| Term                                  | Definition                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Package                               | One or more NC-SI channels in a network controller that share a common set of electrical buffers and common buffer control for the NC-SI bus. Typically, there is a single, logical NC-SI package for a single physical network controller package (chip or module). However, the specification allows a single physical chip or module to hold multiple NC-SI logical packages. |
| Control Traffic/Messages/Packets      | Command, response and notification packets transmitted between BMC and the X550 for the purpose of managing NC-SI.                                                                                                                                                                                                                                                               |
| Pass-Through Traffic/Messages/Packets | Non-control packets passed between the external network and the BMC through the X550.                                                                                                                                                                                                                                                                                            |
| Channel Arbitration                   | Refer to operations where more than one of the network controller channels can be enabled to transmit pass-through packets to the BMC at the same time, where arbitration of access to the RXD, CRS_DV, and RX_ER signal lines is accomplished either by software or hardware means.                                                                                             |
| Logically Enabled/Disabled NC         | Refers to the state of the network controller wherein pass-through traffic is able/unable to flow through the sideband interface to and from the management controller, as a result of issuing Enable/Disable Channel command.                                                                                                                                                   |
| NC RX                                 | Defined as the direction of ingress traffic on the external network controller interface                                                                                                                                                                                                                                                                                         |
| NC TX                                 | Defined as the direction of egress traffic on the external network controller interface                                                                                                                                                                                                                                                                                          |
| NC-SI RX                              | Defined as the direction of ingress traffic on the sideband enhanced NC-SI Interface with respect to the network controller.                                                                                                                                                                                                                                                     |
| NC-SI TX                              | Defined as the direction of egress traffic on the sideband enhanced NC-SI Interface with respect to the network controller.                                                                                                                                                                                                                                                      |

### 11.6.1.2 System Topology

In NC-SI each physical endpoint (NC package) can have several logical slaves (NC channels).

NC-SI defines that one management controller and up to four network controller packages can be connected to the same NC-SI link.

Figure 11-5 shows an example topology for a single BMC and a single NC package. In this example, the NC package has two NC channels.

Figure 11-5. Single NC Package, Two NC Channels

Figure 11-6 shows an example topology for a single BMC and two NC packages. In this example, one NC package has two NC channels and the other has only one NC channel. Scenarios in which the NC-SI lines are shared by multiple NCs (Figure 11-6) mandate an arbitration mechanism. The arbitration mechanism is described in Section 11.6.7.1.

**Figure 11-6. Two NC Packages (Left, with Two NC Channels and Right, with One NC Channel)**

**Note:** Channel numbers should match PCI function numbers. If more than one function is defined on a port, the function with the lowest value associated with this port is used (it is assumed that the first function numbers are assigned to different ports). The association of functions to ports is reflected in the *PFGEN\_PORTNUM* registers.

### 11.6.1.3 Data Transport

Since NC-SI is based upon the RMIi transport layer, data is transferred in the form of Ethernet frames. NC-SI defines two types of transmitted frames:

- Control frames:
  - Configures and control the interface
  - Identified by a unique EtherType in their L2 header
- Pass-through frames:
  - Actual LAN pass-through frames transferred from/to the BMC
  - Identified as not being a control frame
  - Attributed to a specific NC channel by their source MAC Address (as configured in the NC by the BMC)

### 11.6.1.3.1 Control Frames

NC-SI control frames are identified by a unique NC-SI EtherType (0x88F8).

Control frames are used in a single-threaded operation, meaning commands are generated only by the BMC and can only be sent one at a time. Each command from the BMC is followed by a single response from the NC (command-response flow), after which the BMC is allowed to send a new command.

The only exception to the command-response flow is the Asynchronous Event Notification (AEN). These control frames are sent unsolicited from the NC to the BMC.

AEN functionality by the NC must be disabled by default, until activated by the BMC using the Enable AEN commands.

To be considered a valid command, a control frame must:

- Comply with the NC-SI header format.
- Be targeted to a valid channel in the package via the *Package ID* and *Channel ID* fields. For example, to target a NC channel with package ID of 0x2 and internal channel ID of 0x5, the BMC must set the channel ID inside the control frame to 0x45. The channel ID is composed of three bits of package ID and five bits of internal channel ID.
- Contain a correct payload checksum (if used).
- Meet any other condition defined by NC-SI.

There are also commands (such as select package) targeted to the package as a whole. These commands must use an internal channel ID of 0x1F.

For details, refer to the NC-SI specification.

### 11.6.1.3.2 NC-SI Frames Receive Flow

Figure 11-7 shows the flow for frames received on the NC from the BMC.

**Figure 11-7. NC-SI Frames Receive Flow for the NC**

## 11.6.2 NC-SI Standard Support

### 11.6.2.1 Supported Features

The X550 supports all the mandatory features of the NC-SI specification (rev 1.0.1). [Table 11-27](#) lists the supported commands.

[Table 11-28](#) lists optional features supported.

**Table 11-27. Supported NC-SI Commands**

| Command                                | Supported over RMII | Supported over MCTP with Pass-Through | Supported over MCTP without Pass-Through |
|----------------------------------------|---------------------|---------------------------------------|------------------------------------------|
| Clear initial state                    | Yes                 | Yes                                   | Yes                                      |
| Get Version ID                         | Yes                 | Yes                                   | Yes                                      |
| Get Parameters                         | Yes                 | Yes                                   | Yes                                      |
| Get Controller Packet Statistics       | Yes, partially      | Yes, partially                        | Yes, partially                           |
| Get Link Status                        | Yes                 | Yes                                   | Yes                                      |
| Enable Channel                         | Yes                 | Yes                                   | Yes                                      |
| Disable Channel                        | Yes                 | Yes                                   | Yes                                      |
| Reset Channel                          | Yes                 | Yes                                   | Yes                                      |
| Enable VLAN                            | Yes <sup>1,2</sup>  | Yes <sup>1</sup>                      | No <sup>3</sup>                          |
| Disable VLAN                           | Yes                 | Yes                                   | No <sup>3</sup>                          |
| Enable Broadcast Filter                | Yes                 | Yes                                   | No <sup>3</sup>                          |
| Disable Broadcast Filter               | Yes                 | Yes                                   | No <sup>3</sup>                          |
| Set MAC Address <sup>4</sup>           | Yes                 | Yes                                   | No <sup>3</sup>                          |
| Get NC-SI Statistics                   | Yes, partially      | Yes, partially                        | Yes, partially                           |
| Set NC-SI Flow-Control                 | Yes                 | No                                    | No <sup>3</sup>                          |
| Set Link Command                       | Yes                 | Yes                                   | Yes                                      |
| Enable Global multicast Filter         | Yes                 | Yes                                   | No <sup>3</sup>                          |
| Disable Global multicast Filter        | Yes                 | Yes                                   | No <sup>3</sup>                          |
| Get Capabilities                       | Yes                 | Yes                                   | Yes                                      |
| Set VLAN Filters                       | Yes                 | Yes                                   | No <sup>3</sup>                          |
| AEN Enable                             | Yes                 | Yes                                   | Yes                                      |
| Get NC-SI Pass-Through Statistics      | Yes, partially      | Yes, partially                        | No <sup>3</sup>                          |
| Select Package                         | Yes                 | Yes                                   | Yes                                      |
| Deselect Package                       | Yes                 | Yes                                   | Yes                                      |
| Enable Channel Network Tx <sup>5</sup> | Yes                 | Yes                                   | No                                       |
| Disable Channel Network Tx             | Yes                 | Yes                                   | No                                       |
| OEM Command <sup>6</sup>               | Yes                 | Yes                                   | Yes                                      |

1. In cases that one of the LAN devices is assigned for the sole use of the manageability and its LAN PCI-E function is disabled, using the NC-SI Set Link command while advertising multiple speeds and enabling auto-negotiation, results in the lowest possible speed chosen. To enable link of higher a speed, the BMC should not advertise speeds that are below the desired link speed. When doing it, changing the power state of the LAN device has no effect and the link speed is not re-negotiated.
2. The X550 does not support filtering of User priority/DEI Bits of VLAN.

3. In MCTP without pass-through mode, only control commands are supported and not pass-through traffic - thus many of the regular NC-SI commands are not supported or are supported in a limited manner, only to allow control and status reporting for the device.
4. Set MAC Address command fails with a 0x002 (Parameter Is Invalid, Unsupported, or Out-of-Range) reason code if received on a Tx enabled port with a unicast MAC Address already configured on another Tx enabled port.
5. Enable Channel Network TX command fails with a 0x002 (Parameter Is Invalid, Unsupported, or Out-of-Range) reason code if received on a port configured with a unicast MAC address equal to the MAC address of another Tx enabled port.
6. See [Section 11.6.3](#) for details.

**Table 11-28. Optional NC-SI Features Support**

| Feature                                  | Implement      | Details                                                                                                                                                                                                                               |
|------------------------------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AENs                                     | Yes            | The Driver state AEN may be emitted up to 1 minute after actual driver change if the driver was taken down unexpectedly.<br>A "Re-configuration Required" AEN is sent before a firmware reset initiated due to a firmware code update |
| Get Controller Packet Statistics command | Yes, partially | Supports the following counters <sup>1</sup> :<br>2-8, 13-16 <sup>2</sup><br>The statistics are cleared between reads.                                                                                                                |
| Get NC-SI statistics                     | Yes            | Supports all counters                                                                                                                                                                                                                 |
| Get NC-SI Pass-Through Statistics        | Yes, partially | Support the following counters <sup>3</sup> :<br>1 <sup>4</sup> , 2, 6 <sup>5</sup> , 7                                                                                                                                               |
| VLAN Modes                               | Yes, partially | Support only modes 1, 3.                                                                                                                                                                                                              |
| Buffering Capabilities                   | Yes            | 8 Kb <sup>6</sup>                                                                                                                                                                                                                     |
| MAC Address Filters                      | Yes            | Supports 2 MAC Addresses per port.                                                                                                                                                                                                    |
| Channel Count                            | Yes            | Supports 4 channels.                                                                                                                                                                                                                  |
| VLAN Filters                             | Yes            | Support 8 VLAN filters per port.<br>Filtering is ignoring the <i>DEI</i> bit and the 802.1P priority bits                                                                                                                             |
| Broadcast Filters                        | Yes            | Support the following filters: <ul style="list-style-type: none"><li>• ARP</li><li>• DHCP</li><li>• Net BIOS</li></ul>                                                                                                                |
| Multicast Filters                        | Yes            | Supports the following filters: <ul style="list-style-type: none"><li>• IPv6 Neighbor Advertisement</li><li>• IPv6 Router Advertisement</li><li>• DHCPv6 relay and server multicast</li></ul>                                         |
| Hardware Arbitration                     | Yes            | Supports NC-SI hardware arbitration.                                                                                                                                                                                                  |

1. *TCTL.EN* should be set to 1b to activate Tx related counters and *RCTL.RXEN*, *MANC.RCV\_EN* or *GRC.APME* should be set to enable RX related counters.
2. As described in the Get Controller Packet Statistics Counter Numbers table in NC-SI specification.
3. As described in the Get NC-SI Pass-through Statistics Counters table in NC-SI specification.
4. If OS2BMC traffic is enabled, packets sent both to the net and to the host are counted twice by this counter.
5. The Total Pass-through RX Packets Received On the LAN Interface counter includes also OS2BMC traffic.
6. For OS2BMC traffic, there may be drops after 4 KB.

### 11.6.2.2 ALD Support

NC-SI PHY power down conditions:

In NC-SI mode, the device may dynamically change the PHY power mode according to the NC-SI channel state assuming no other functionality requires the PHY to be active (host or wake-up).

The following algorithm is used to define if PHY activity is required:

- At init time, if the manageability mode is NC-SI, PHY is required to be active only if the *Enable All PHYs in D3 N* bit in *Common Firmware Parameters* NVM word is set.
- Once a channel is enabled via Enable Channel NC-SI command, The PHY is powered up.
- If the channel is disabled via a Disable Channel command with *ALD* bit set, the PHY is disabled.
- If the channel is disabled via a Reset Channel command, the PHY power state is set back to the init value as define by the *Enable All PHYs in D3 N* bit.

**Note:** Before transitioning to D3 it is the responsibility of the driver to request the PHY to be active for wake-up activities using WUC register (setting WUC.PROXYE forces PHY to be active in D3).

### 11.6.2.3 AEN Handling

Asynchronous events may occur when the device is not allowed to send them. The following rules defines the behavior of the X550 in these cases:

1. While the device is disabled, for each type of AEN only the last event is kept
2. Outstanding AENs that occurred while package was deselected are transmitted when package is selected.
3. On a transition from Channel Disabled to Channel Enabled, all outstanding event are erased to prevent stale events notifications.

## 11.6.3 NC-SI Mode — Intel Specific Commands

In addition to regular NC-SI commands, the following Intel vendor specific commands are supported. The purpose of these commands is to provide a means for the BMC to access some of the Intel-specific features present in the X550.

### 11.6.3.1 Overview

The following features are available via the NC-SI OEM specific commands:

- Receive filters.
- Packet Addition Decision Filters 0x0...0x4.
- Packet Reduction Decision Filters 0x5...0x7.
- *MNGONLY* register (controls the forwarding of manageability packets to the host).
- Flex 128 filters.
- Flex TCP/UDP port filters 0x0...0x2.

- IPv4/IPv6 filters.
- Get System MAC Address — This command enables the BMC to retrieve the system MAC Address used by the NC. This MAC Address can be used for a shared MAC Address mode.
- Keep PHY Link Up (Veto bit) Enable/Disable — This feature enables the BMC to block PHY reset, which might cause session loss.
- TCO Reset — Enables the BMC to reset the X550.
- Checksum offloading — Offloads IP/UDP/TCP checksum checking from the BMC.
- OS2BMC control commands.
- Firmware Version Commands.

These commands are designed to be compliant with their corresponding SMBus commands (if existing). All of the commands are based on a single DMTF defined NC-SI command, known as OEM Command. This command is as follows.

### 11.6.3.2 OEM Command (0x50)

The OEM command can be used by the BMC to request the sideband interface to provide vendor-specific information. The Vendor Enterprise Number (VEN) is the unique MIB/SNMP private enterprise number assigned by IANA per organization. Vendors are free to define their own internal data structures in the vendor data fields.

|         | Bits                          |               |                           |     |
|---------|-------------------------------|---------------|---------------------------|-----|
| Bytes   | 31:24                         | 23:16         | 15:8                      | 7:0 |
| 0...3   | NC-SI Header                  |               |                           |     |
| 4...7   |                               |               |                           |     |
| 8...11  |                               |               |                           |     |
| 12...15 |                               |               |                           |     |
| 16...19 | Manufacturer ID (Intel 0x157) |               |                           |     |
| 20...   | Intel Command Number          | Optional Data |                           |     |
| ...     | ...                           |               |                           |     |
| ...     | Optional Data                 |               | Padding to 32 bits (0x00) |     |
| ...     | Checksum                      |               |                           |     |

### 11.6.3.2.1 OEM Response (0xD0)

|         | Bits                          |                      |                           |     |
|---------|-------------------------------|----------------------|---------------------------|-----|
| Bytes   | 31:24                         | 23:16                | 15:8                      | 7:0 |
| 0...3   | NC-SI Header                  |                      |                           |     |
| 4...7   |                               |                      |                           |     |
| 8...11  |                               |                      |                           |     |
| 12...15 |                               |                      |                           |     |
| 16...19 | Response Code                 |                      | Reason Code               |     |
| 20...23 | Manufacturer ID (Intel 0x157) |                      |                           |     |
| 24...27 | Intel Command Number          | Optional Return Data |                           |     |
| ...     | ...                           |                      |                           |     |
| ...     | Optional Return Data          |                      | Padding to 32 bits (0x00) |     |
| ...     | Checksum                      |                      |                           |     |

**Note:** Responses have no command-specific reason code, unless otherwise specified within the command.

**Note:** The commands/responses described below includes only the part up to the Data. The padding and checksum are implied.

### 11.6.3.3 OEM Commands Summary

**Table 11-29. OEM Specific Command Response Reason Codes**

| Response Code |                | Reason Code |                                        |
|---------------|----------------|-------------|----------------------------------------|
| Value         | Description    | Value       | Description                            |
| 0x1           | Command Failed | 0x5081      | Invalid Intel Command Number           |
|               |                | 0x5082      | Invalid Intel Command Parameter Number |
|               |                | 0x5085      | Internal Network Controller Error      |
|               |                | 0x5086      | Invalid Vendor Enterprise Code         |

**Table 11-30. OEM Commands Summary**

| Intel Command | Parameter | Command Name           | Supported in MCTP without PT | Page |
|---------------|-----------|------------------------|------------------------------|------|
| 0x00          | 0x00      | Set IP Filters Control | No                           | 916  |
| 0x01          | 0x00      | Get IP Filters Control | No                           | 917  |

**Table 11-30. OEM Commands Summary (Continued)**

| Intel Command | Parameter | Command Name                                    | Supported in MCTP without PT | Page                |
|---------------|-----------|-------------------------------------------------|------------------------------|---------------------|
| 0x02          | 0x0F      | Set Manageability Only                          | No                           | <a href="#">919</a> |
|               | 0x10      | Set Flexible 128 Filter Mask and Length         |                              | <a href="#">920</a> |
|               | 0x11      | Set Flexible 128 Filter Data                    |                              | <a href="#">921</a> |
|               | 0x63      | Set Flex TCP/UDP Port Filters                   |                              | <a href="#">922</a> |
|               | 0x64      | Set Flex IPv4 Address Filters                   |                              | <a href="#">923</a> |
|               | 0x65      | Set Flex IPv6 Address Filters                   |                              | <a href="#">924</a> |
|               | 0x67      | Set EtherType Filter                            |                              | <a href="#">925</a> |
|               | 0x68      | Set Packet Addition Extended Filter             |                              | <a href="#">926</a> |
| 0x03          | 0x0F      | Get Manageability Only                          | No                           | <a href="#">928</a> |
|               | 0x10      | Get Flexible 128 Filter Mask and Length         |                              | <a href="#">929</a> |
|               | 0x11      | Get Flexible 128 Filter Data                    |                              | <a href="#">930</a> |
|               | 0x63      | Get Flex TCP/UDP Port Filters                   |                              | <a href="#">931</a> |
|               | 0x64      | Get Flex IPv4 Address Filters                   |                              | <a href="#">932</a> |
|               | 0x65      | Get Flex IPv6 Address Filters                   |                              | <a href="#">933</a> |
|               | 0x67      | Get EtherType Filter                            |                              | <a href="#">934</a> |
|               | 0x68      | Get Packet Addition Extended Filter             |                              | <a href="#">935</a> |
| 0x04          | 0x10      | Set Extended Unicast Packet Reduction           | No                           | <a href="#">936</a> |
|               | 0x11      | Set Extended Multicast Packet Reduction         |                              | <a href="#">938</a> |
|               | 0x12      | Set Extended Broadcast Packet Reduction         |                              | <a href="#">940</a> |
| 0x05          | 0x10      | Get Extended Unicast Packet Reduction           | No                           | <a href="#">941</a> |
|               | 0x11      | Get Extended Multicast Packet Reduction         |                              | <a href="#">942</a> |
|               | 0x12      | Get Extended Broadcast Packet Reduction         |                              | <a href="#">942</a> |
| 0x06          | N/A       | Get System MAC Address                          | Yes                          | <a href="#">943</a> |
| 0x20          | N/A       | Set Intel Management Control                    | No                           | <a href="#">944</a> |
| 0x21          | N/A       | Get Intel Management Control                    | No                           | <a href="#">945</a> |
| 0x22          | N/A       | Perform TCO Reset                               | Yes                          | <a href="#">946</a> |
| 0x23          | N/A       | Enable IP/UDP/TCP Checksum Offloading           | No                           | <a href="#">948</a> |
| 0x24          | N/A       | Disable IP/UDP/TCP Checksum Offloading          | No                           | <a href="#">949</a> |
| 0x40          | 0x01      | Enable OS2BMC Flow                              | No                           | <a href="#">950</a> |
|               | 0x02      | Enable Network to BMC Flow                      |                              | <a href="#">950</a> |
|               | 0x03      | Enable Both Network to BMC and Host to BMC Flow |                              | <a href="#">951</a> |
|               | 0x04      | Set BMC IP Address                              | Yes                          | <a href="#">952</a> |
| 0x41          | N/A       | Get OS2BMC Parameters                           | No                           | <a href="#">953</a> |
| 0x48          | 0x1       | Get Controller Information                      | Yes                          | <a href="#">955</a> |
| 0x4C          | 0x0       | Get Thermal Sensor Capabilities                 | Yes                          | <a href="#">957</a> |
|               | 0x1       | Get Thermal Sensor Configuration                |                              | <a href="#">959</a> |
|               | 0x2       | Get Thermal Sensor Status                       |                              | <a href="#">960</a> |

Table 11-30. OEM Commands Summary (Continued)

| Intel Command | Parameter | Command Name                     | Supported in MCTP without PT | Page |
|---------------|-----------|----------------------------------|------------------------------|------|
| 0x4D          | 0x1       | Set Thermal Sensor Configuration | Yes                          | 961  |
|               | 0x2       | Set Thermal Action               |                              | 962  |

**Note:** All the commands are supported both over RMII NC-SI and over MCTP.

### 11.6.3.4 Proprietary Commands Format

#### 11.6.3.4.1 Set Intel Filters Control Command (Intel Command 0x00)

| Bits    |                               |                      |      |     |
|---------|-------------------------------|----------------------|------|-----|
| Bytes   | 31:24                         | 23:16                | 15:8 | 7:0 |
| 0...3   | NC-SI Header                  |                      |      |     |
| 4...7   |                               |                      |      |     |
| 8...11  |                               |                      |      |     |
| 12...15 |                               |                      |      |     |
| 16...19 | Manufacturer ID (Intel 0x157) |                      |      |     |
| 20...23 | 0x00                          | Filter Control Index |      |     |

#### 11.6.3.4.2 Set Intel Filters Control Response Format (Intel Command 0x00)

|         | Bits                          |                      |             |     |
|---------|-------------------------------|----------------------|-------------|-----|
| Bytes   | 31:24                         | 23:16                | 15:8        | 7:0 |
| 0...3   | NC-SI Header                  |                      |             |     |
| 4...7   |                               |                      |             |     |
| 8...11  |                               |                      |             |     |
| 12...15 |                               |                      |             |     |
| 16...19 | Response Code                 |                      | Reason Code |     |
| 20...23 | Manufacturer ID (Intel 0x157) |                      |             |     |
| 24...27 | 0x00                          | Filter Control Index |             |     |

### 11.6.3.5 Set Intel Filters Control — IP Filters Control Command (Intel Command 0x00, Filter Control Index 0x00)

This command controls different aspects of the Intel filters.

| Bytes   | Bits                          |       |                          |     |
|---------|-------------------------------|-------|--------------------------|-----|
|         | 31:24                         | 23:16 | 15:8                     | 7:0 |
| 0...3   | NC-SI Header                  |       |                          |     |
| 4...7   |                               |       |                          |     |
| 8...11  |                               |       |                          |     |
| 12...15 |                               |       |                          |     |
| 16...19 | Manufacturer ID (Intel 0x157) |       |                          |     |
| 20...23 | 0x00                          | 0x00  | IP Filters control (3-2) |     |
| 24...27 | IP Filters Control (1-0)      |       |                          |     |

Where “IP Filters Control” has the following format.

| Bit(s) | Name           | Description                                                                                                                  | Default Value |
|--------|----------------|------------------------------------------------------------------------------------------------------------------------------|---------------|
| 0      | IPv4/IPv6 Mode | IPv6 (0b): There are zero IPv4 filters and four IPv6 filters<br>IPv4 (1b): There are four IPv4 filters and four IPv6 filters | 1b            |
| 31:1   | Reserved       |                                                                                                                              |               |

#### 11.6.3.5.1 Set Intel Filters Control — IP Filters Control Response (Intel Command 0x00, Filter Control Index 0x00)

|         | Bits                          |       |             |     |
|---------|-------------------------------|-------|-------------|-----|
| Bytes   | 31:24                         | 23:16 | 15:8        | 7:0 |
| 0...3   | NC-SI Header                  |       |             |     |
| 4...7   |                               |       |             |     |
| 8...11  |                               |       |             |     |
| 12...15 |                               |       |             |     |
| 16...19 | Response Code                 |       | Reason Code |     |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |     |
| 24...27 | 0x00                          | 0x00  |             |     |

### 11.6.3.6 Get Intel Filters Control Commands (Intel Command 0x01)

#### 11.6.3.6.1 Get Intel Filters Control — IP Filters Control Command (Intel Command 0x01, Filter Control Index 0x00)

This command controls different aspects of the Intel filters.

| Bytes   | Bits                          |       |      |     |
|---------|-------------------------------|-------|------|-----|
|         | 31:24                         | 23:16 | 15:8 | 7:0 |
| 0...3   | NC-SI Header                  |       |      |     |
| 4...7   |                               |       |      |     |
| 8...11  |                               |       |      |     |
| 12...15 |                               |       |      |     |
| 16...19 | Manufacturer ID (Intel 0x157) |       |      |     |
| 20...21 | 0x01                          | 0x00  |      |     |

#### 11.6.3.6.1.1 Get Intel Filters Control — IP Filters Control Response (Intel Command 0x01, Filter Control Index 0x00)

|         | Bits                          |       |                          |     |
|---------|-------------------------------|-------|--------------------------|-----|
| Bytes   | 31:24                         | 23:16 | 15:8                     | 7:0 |
| 0...3   | NC-SI Header                  |       |                          |     |
| 4...7   |                               |       |                          |     |
| 8...11  |                               |       |                          |     |
| 12...15 |                               |       |                          |     |
| 16...19 | Response Code                 |       | Reason Code              |     |
| 20...23 | Manufacturer ID (Intel 0x157) |       |                          |     |
| 24...27 | 0x01                          | 0x00  | IP Filters Control (3-2) |     |
| 28...29 | IP Filters Control (1-0)      |       |                          |     |

## 11.6.3.7 Set Intel Filters Formats

### 11.6.3.7.1 Set Intel Filters Command (Intel Command 0x02)

| Bytes   | Bits                          |                  |                         |     |
|---------|-------------------------------|------------------|-------------------------|-----|
|         | 31:24                         | 23:16            | 15:8                    | 7:0 |
| 0...3   | NC-SI Header                  |                  |                         |     |
| 4...7   |                               |                  |                         |     |
| 8...11  |                               |                  |                         |     |
| 12...15 |                               |                  |                         |     |
| 16...19 | Manufacturer ID (Intel 0x157) |                  |                         |     |
| 20...21 | 0x02                          | Parameter Number | Filters Data (optional) |     |

#### 11.6.3.7.1.1 Set Intel Filters Response (Intel Command 0x02)

|         | Bits                          |                      |                        |     |
|---------|-------------------------------|----------------------|------------------------|-----|
| Bytes   | 31:24                         | 23:16                | 15:8                   | 7:0 |
| 0...3   | NC-SI Header                  |                      |                        |     |
| 4...7   |                               |                      |                        |     |
| 8...11  |                               |                      |                        |     |
| 12...15 |                               |                      |                        |     |
| 16...19 | Response Code                 |                      | Reason Code            |     |
| 20...23 | Manufacturer ID (Intel 0x157) |                      |                        |     |
| 24...   | 0x02                          | Filter Control Index | Return Data (Optional) |     |

### 11.6.3.7.2 Set Intel Filters — Manageability Only Command (Intel Command 0x02, Filter Parameter 0x0F)

This command sets the MNGONLY register. The MNGONLY register controls whether pass-through packets destined to the BMC are not forwarded to the Host OS. The MNGONLY register is described in Table 11-4.

| Bytes   | Bits                          |       |                          |     |
|---------|-------------------------------|-------|--------------------------|-----|
|         | 31:24                         | 23:16 | 15:8                     | 7:0 |
| 0...3   | NC-SI Header                  |       |                          |     |
| 4...7   |                               |       |                          |     |
| 8...11  |                               |       |                          |     |
| 12...15 |                               |       |                          |     |
| 16...19 | Manufacturer ID (Intel 0x157) |       |                          |     |
| 20...23 | 0x02                          | 0x0F  | Manageability Only (3-2) |     |
| 24...25 | Manageability Only (1-0)      |       |                          |     |

#### 11.6.3.7.2.1 Set Intel Filters — Manageability Only Response (Intel Command 0x02, Filter Parameter 0x0F)

|         | Bits                          |       |             |     |
|---------|-------------------------------|-------|-------------|-----|
| Bytes   | 31:24                         | 23:16 | 15:8        | 7:0 |
| 0...3   | NC-SI Header                  |       |             |     |
| 4...7   |                               |       |             |     |
| 8...11  |                               |       |             |     |
| 12...15 |                               |       |             |     |
| 16...19 | Response Code                 |       | Reason Code |     |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |     |
| 24...25 | 0x02                          | 0x0F  |             |     |

### 11.6.3.7.3 Set Intel Filters — Flex Filter Enable Mask and Length Command (Intel Command 0x02, Filter Parameter 0x10)

The following command sets the Intel flex filters mask and length.

| Bytes   | Bits                          |              |             |             |
|---------|-------------------------------|--------------|-------------|-------------|
|         | 31:24                         | 23:16        | 15:8        | 7:0         |
| 0...3   | NC-SI Header                  |              |             |             |
| 4...7   |                               |              |             |             |
| 8...11  |                               |              |             |             |
| 12...15 |                               |              |             |             |
| 16...19 | Manufacturer ID (Intel 0x157) |              |             |             |
| 20...23 | 0x02                          | 0x10         | Mask Byte 1 | Mask Byte 2 |
| 24...27 | ...                           | ...          | ...         | ...         |
| 28...31 | ...                           | ...          | ...         | ...         |
| 32...35 | ...                           | ...          | ...         | ...         |
| 36...37 | Mask Byte 15                  | Mask Byte 16 | Reserved    | Reserved    |
| 38      | Length                        |              |             |             |

#### 11.6.3.7.3.1 Set Intel Filters — Flex Filter Enable Mask and Length Response (Intel Command 0x02, Filter Parameter 0x10)

|         | Bits                          |       |             |     |
|---------|-------------------------------|-------|-------------|-----|
| Bytes   | 31:24                         | 23:16 | 15:8        | 7:0 |
| 0...3   | NC-SI Header                  |       |             |     |
| 4...7   |                               |       |             |     |
| 8...11  |                               |       |             |     |
| 12...15 |                               |       |             |     |
| 16...19 | Response Code                 |       | Reason Code |     |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |     |
| 24...25 | 0x02                          | 0x10  |             |     |

#### 11.6.3.7.4 Set Intel Filters — Flex Filter Data Command (Intel Command 0x02, Filter Parameter 0x11)

| Bytes   | Bits                          |               |                   |               |
|---------|-------------------------------|---------------|-------------------|---------------|
|         | 31:24                         | 23:16         | 15:8              | 7:0           |
| 0...3   | NC-SI Header                  |               |                   |               |
| 4...7   |                               |               |                   |               |
| 8...11  |                               |               |                   |               |
| 12...15 |                               |               |                   |               |
| 16...19 | Manufacturer ID (Intel 0x157) |               |                   |               |
| 20...   | 0x02                          | 0x11          | Filter Data Group | Filter Data 1 |
|         | ...                           | Filter Data N |                   |               |

The Filter Data Group parameter defines which bytes of the Flex filter are set by this command:

**Table 11-31. Filter Data Group**

| Code | Bytes Programmed | Filter Data Length |
|------|------------------|--------------------|
| 0x0  | Bytes 0–29       | 1–30               |
| 0x1  | Bytes 30–59      | 1–30               |
| 0x2  | Bytes 60–89      | 1–30               |
| 0x3  | Bytes 90–119     | 1–30               |
| 0x4  | Bytes 120–127    | 1–8                |

**Note:** Using this command to configure the filters data must be done after the flex filter mask command is issued and the mask is set.

##### 11.6.3.7.4.1 Set Intel Filters — Flex Filter Data Response (Intel Command 0x02, Filter Parameter 0x11)

|         | Bits                          |       |             |     |
|---------|-------------------------------|-------|-------------|-----|
| Bytes   | 31:24                         | 23:16 | 15:8        | 7:0 |
| 0...3   | NC-SI Header                  |       |             |     |
| 4...7   |                               |       |             |     |
| 8...11  |                               |       |             |     |
| 12...15 |                               |       |             |     |
| 16...19 | Response Code                 |       | Reason Code |     |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |     |
| 24...25 | 0x02                          | 0x11  |             |     |

### 11.6.3.7.5 Set Intel Filters — Flex TCP/UDP Port Filter Command (Intel Command 0x02, Filter Parameter 0x63)

| Bytes   | Bits                          |       |                   |                  |
|---------|-------------------------------|-------|-------------------|------------------|
|         | 31:24                         | 23:16 | 15:8              | 7:0              |
| 0...3   | NC-SI Header                  |       |                   |                  |
| 4...7   |                               |       |                   |                  |
| 8...11  |                               |       |                   |                  |
| 12...15 |                               |       |                   |                  |
| 16...19 | Manufacturer ID (Intel 0x157) |       |                   |                  |
| 20...23 | 0x02                          | 0x63  | Port filter index | TCP/UDP Port MSB |
| 24      | TCP/UDP Port LSB              |       |                   |                  |

Filter index range: 0x0...0xA.

If the filter index is bigger than 10, a command failed Response Code is returned with Invalid Intel Parameter Number reason (0x5082).

#### 11.6.3.7.5.1 Set Intel Filters — Flex TCP/UDP Port Filter Response (Intel Command 0x02, Filter Parameter 0x63)

|         | Bits                          |       |             |     |
|---------|-------------------------------|-------|-------------|-----|
| Bytes   | 31:24                         | 23:16 | 15:8        | 7:0 |
| 0...3   | NC-SI Header                  |       |             |     |
| 4...7   |                               |       |             |     |
| 8...11  |                               |       |             |     |
| 12...15 |                               |       |             |     |
| 16...19 | Response Code                 |       | Reason Code |     |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |     |
| 24...25 | 0x02                          | 0x63  |             |     |

### 11.6.3.7.6 Set Intel Filters — IPv4 Filter Command (Intel Command 0x02, Filter Parameter 0x64)

| Bytes   | Bits                          |       |                 |                  |
|---------|-------------------------------|-------|-----------------|------------------|
|         | 31:24                         | 23:16 | 15:8            | 7:0              |
| 0...3   | NC-SI Header                  |       |                 |                  |
| 4...7   |                               |       |                 |                  |
| 8...11  |                               |       |                 |                  |
| 12...15 |                               |       |                 |                  |
| 16...19 | Manufacturer ID (Intel 0x157) |       |                 |                  |
| 20...23 | 0x02                          | 0x64  | IP filter index | IPv4 Address (3) |
| 24...26 | IPv4 Address (2-0)            |       |                 |                  |

**Note:** The filters index range can vary according to the IPv4/IPv6 mode setting in the Filters Control command.

IPv4 Mode: Filter index range: 0x0...0x3.

IPv6 Mode: This command should not be used in IPv6 mode.

#### 11.6.3.7.6.1 Set Intel Filters — IPv4 Filter Response (Intel Command 0x02, Filter Parameter 0x64)

|         | Bits                          |       |             |     |
|---------|-------------------------------|-------|-------------|-----|
| Bytes   | 31:24                         | 23:16 | 15:8        | 7:0 |
| 0...3   | NC-SI Header                  |       |             |     |
| 4...7   |                               |       |             |     |
| 8...11  |                               |       |             |     |
| 12...15 |                               |       |             |     |
| 16...19 | Response Code                 |       | Reason Code |     |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |     |
| 24...25 | 0x02                          | 0x64  |             |     |

If the IPv4 address equals all zero, a command failed Response Code is returned, with Invalid Intel Parameter Number reason (0x5082).

### 11.6.3.7.7 Set Intel Filters — IPv6 Filter Command (Intel Command 0x02, Filter Parameter 0x65)

| Bytes   | Bits                          |       |                            |                             |
|---------|-------------------------------|-------|----------------------------|-----------------------------|
|         | 31:24                         | 23:16 | 15:8                       | 7:0                         |
| 0...3   | NC-SI Header                  |       |                            |                             |
| 4...7   |                               |       |                            |                             |
| 8...11  |                               |       |                            |                             |
| 12...15 |                               |       |                            |                             |
| 16...19 | Manufacturer ID (Intel 0x157) |       |                            |                             |
| 20...23 | 0x02                          | 0x65  | IP filter index            | IPv6 Address (MSB, byte 15) |
| 24...27 | ...                           | ...   | ...                        | ...                         |
| 28...31 | ...                           | ...   | ...                        | ...                         |
| 32...35 | ...                           | ...   | ...                        | ...                         |
| 36...37 | ...                           |       | IPv6 Address (LSB, byte 0) |                             |

**Note:** The filters index range can vary according to the IPv4/IPv6 mode setting in the Filters Control command.

IPv4 Mode: Filter index range: 0x1...0x3.

IPv6 Mode: Filter index range: 0x0...0x3.

#### 11.6.3.7.7.1 Set Intel Filters — IPv6 Filter Response (Intel Command 0x02, Filter Parameter 0x65)

|         | Bits                          |       |             |     |
|---------|-------------------------------|-------|-------------|-----|
| Bytes   | 31:24                         | 23:16 | 15:8        | 7:0 |
| 0...3   | NC-SI Header                  |       |             |     |
| 4...7   |                               |       |             |     |
| 8...11  |                               |       |             |     |
| 12...15 |                               |       |             |     |
| 16...19 | Response Code                 |       | Reason Code |     |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |     |
| 24...25 | 0x02                          | 0x65  |             |     |

If the IP filter index does not match the ranges above, a command failed Response Code is returned, with Invalid Intel Parameter Number reason (0x5082).

If the IPv6 address equals all zero, a command failed Response Code is returned, with Invalid Intel Parameter Number reason (0x5082).

### 11.6.3.7.8 Set Intel Filters - EtherType Filter Command (Intel Command 0x02, Filter Parameter 0x67)

| Bytes   | Bits                          |       |                        |                      |
|---------|-------------------------------|-------|------------------------|----------------------|
|         | 31:24                         | 23:16 | 15:8                   | 7:0                  |
| 0...3   | NC-SI Header                  |       |                        |                      |
| 4...7   |                               |       |                        |                      |
| 8...11  |                               |       |                        |                      |
| 12...15 |                               |       |                        |                      |
| 16...19 | Manufacturer ID (Intel 0x157) |       |                        |                      |
| 20...23 | 0x02                          | 0x67  | EtherType Filter Index | EtherType Filter MSB |
| 24...27 | ...                           | ...   | EtherType Filter LSB   |                      |

Where the EtherType Filter has the format as described in [Section 8.2.2.19.6](#).

#### 11.6.3.7.8.1 Set Intel Filters - EtherType Filter Response (Intel Command 0x02, Filter Parameter 0x67)

|         | Bits                          |       |             |     |
|---------|-------------------------------|-------|-------------|-----|
| Bytes   | 31:24                         | 23:16 | 15:8        | 7:0 |
| 0...3   | NC-SI Header                  |       |             |     |
| 4...7   |                               |       |             |     |
| 8...11  |                               |       |             |     |
| 12...15 |                               |       |             |     |
| 16...19 | Response Code                 |       | Reason Code |     |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |     |
| 24...25 | 0x02                          | 0x67  |             |     |

If the EtherType filter Index is larger than 3, a command failed Response Code is returned with Invalid Intel Parameter Number reason (0x5082).

### 11.6.3.7.9 Set Intel Filters - Packet Addition Extended Decision Filter Command (Intel Command 0x02, Filter Parameter 0x68)

See [Figure 11-2](#) for description of the decision filters structure.

This command overwrites any previously stored value. The value set is not checked.

| Bits    |                               |       |                                |                                |
|---------|-------------------------------|-------|--------------------------------|--------------------------------|
| Bytes   | 31:24                         | 23:16 | 15:8                           | 7:0                            |
| 0...3   | NC-SI Header                  |       |                                |                                |
| 4...7   |                               |       |                                |                                |
| 8...11  |                               |       |                                |                                |
| 12...15 |                               |       |                                |                                |
| 16...19 | Manufacturer ID (Intel 0x157) |       |                                |                                |
| 20...23 | 0x02                          | 0x68  | Extended Decision filter Index | Extended Decision filter 1 MSB |
| 24...27 | ...                           | ...   | Extended Decision filter 1 LSB | Extended Decision filter 0 MSB |
| 28...30 | ...                           | ...   | Extended Decision filter 0 LSB |                                |

Extended Decision filter Index Range: 0...4

Filter 0: See [Table 11-32](#).

Filter 1: See [Table 11-33](#).

**Table 11-32. Filter Values**

| Bit(s) | Name                          | Description                                                                                                                |
|--------|-------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| 1:0    | Unicast (AND)                 | If set, packets must match unicast filter 0 to 1, respectively.                                                            |
| 3:2    | Reserved                      | Reserved.                                                                                                                  |
| 4      | Broadcast (AND)               | If set, packets must match the broadcast filter.                                                                           |
| 12:5   | VLAN (AND)                    | If set, packets must match VLAN filter 0 to 7, respectively.                                                               |
| 16:13  | IPv4 Address (AND)            | If set, packets must match IPv4 filter 0 to 3, respectively                                                                |
| 20:17  | IPv6 Address (AND)            | If set, packets must match IPv4 filter 0 to 3, respectively                                                                |
| 22:21  | Unicast (OR)                  | If set, packets can pass if match unicast filter 0 to 1, respectively, or a different OR filter.                           |
| 24:23  | Reserved                      | Reserved.                                                                                                                  |
| 25     | Broadcast (OR)                | If set, packets can pass if match the broadcast filter or a different OR filter.                                           |
| 26     | Multicast (AND)               | If set, packets must match the multicast filter.                                                                           |
| 27     | ARP Request (OR)              | If set, packets can pass if match the ARP request filter or a different OR filter.                                         |
| 28     | ARP Response (OR)             | If set, packets can pass if match the ARP response filter or a different OR filter.                                        |
| 29     | Neighbor Discovery - 134 (OR) | If set, packets can pass if match the neighbor discovery filter (type134 - router advertisement) or a different OR filter. |
| 30     | Port 0x298 (OR)               | If set, packets can pass if match a fixed TCP/UDP port 0x298 filter or a different OR filter.                              |
| 31     | Port 0x26F (OR)               | If set, packets can pass if match a fixed TCP/UDP port 0x26F filter or a different OR filter.                              |

**Table 11-33. Extended Filter 1 Values**

| Bit(s) | Name                          | Description                                                                                                                |
|--------|-------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| 3:0    | Ethertype 0 -3 (AND)          | If set, packets must match the Ethertype filter 0 to 3, respectively.                                                      |
| 7:4    | Ethertype 0 -3 (OR)           | If set, packets must match the Ethertype filter 0 to 3, respectively, or a different OR filter.                            |
| 18:8   | Flex port 10:0 (OR)           | If set, packets can pass if match the TCP/UDP Port filter 10:0.                                                            |
| 19     | DHCPv6 (OR)                   | If set, packets can pass if match the DHCPv6 port (0x0223).                                                                |
| 20     | DHCP Client (OR)              | If set, packets can pass if match the DHCP Server port (0x0043).                                                           |
| 21     | DHCP Server (OR)              | If set, packets can pass if match the DHCP Client port (0x0044).                                                           |
| 22     | NetBIOS Name Service (OR)     | If set, packets can pass if match the NetBIOS Name Service port (0x0089).                                                  |
| 23     | NetBIOS Datagram Service (OR) | If set, packets can pass if match the NetBIOS Datagram Service port (0x008A).                                              |
| 24     | Flex TCO (OR)                 | If set, packets can pass if match the Flex 128 TCO filter.                                                                 |
| 25     | Neighbor Discovery - 135 (OR) | If set, packets must also match the neighbor discovery filter (type135 - Neighbor Solicitation. or a different OR filter.  |
| 26     | Neighbor Discovery - 136 (OR) | If set, packets must also match the neighbor discovery filter (type136 - Neighbor Advertisement) or a different OR filter. |
| 27     | Neighbor Discovery - 137 (OR) | If set, packets must also match the neighbor discovery filter (type137 - Redirect) or a different OR filter.               |
| 28     | Reserved                      | Reserved.                                                                                                                  |
| 29     | MLD (OR)                      | If set, packets must also match one of the MLD ICMPv6 types or a different OR filter.                                      |
| 31:30  | Reserved                      | Reserved.                                                                                                                  |

#### 11.6.3.7.9.1 Set Intel Filters – Packet Addition Extended Decision Filter Response (Intel Command 0x02, Filter Parameter 0x68)

|         | Bits                          |       |             |     |
|---------|-------------------------------|-------|-------------|-----|
| Bytes   | 31:24                         | 23:16 | 15:8        | 7:0 |
| 0...3   | NC-SI Header                  |       |             |     |
| 4...7   |                               |       |             |     |
| 8...11  |                               |       |             |     |
| 12...15 |                               |       |             |     |
| 16...19 | Response Code                 |       | Reason Code |     |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |     |
| 24...25 | 0x02                          | 0x68  |             |     |

If the Extended Decision filter Index is bigger than 5, a command failed Response Code is returned with Invalid Intel Parameter Number reason (0x5082).

## 11.6.3.8 Get Intel Filters Formats

### 11.6.3.8.1 Get Intel Filters Command (Intel Command 0x03)

| Bytes   | Bits                          |                  |      |     |
|---------|-------------------------------|------------------|------|-----|
|         | 31:24                         | 23:16            | 15:8 | 7:0 |
| 0...3   | NC-SI Header                  |                  |      |     |
| 4...7   |                               |                  |      |     |
| 8...11  |                               |                  |      |     |
| 12...15 |                               |                  |      |     |
| 16...19 | Manufacturer ID (Intel 0x157) |                  |      |     |
| 20...21 | 0x03                          | Parameter Number |      |     |

#### 11.6.3.8.1.1 Get Intel Filters Response (Intel Command 0x03)

|         | Bits                          |                  |                      |     |
|---------|-------------------------------|------------------|----------------------|-----|
| Bytes   | 31:24                         | 23:16            | 15:8                 | 7:0 |
| 0...3   | NC-SI Header                  |                  |                      |     |
| 4...7   |                               |                  |                      |     |
| 8...11  |                               |                  |                      |     |
| 12...15 |                               |                  |                      |     |
| 16...19 | Response Code                 |                  | Reason Code          |     |
| 20...23 | Manufacturer ID (Intel 0x157) |                  |                      |     |
| 24...25 | 0x03                          | Parameter Number | Optional Return Data |     |

#### 11.6.3.8.2 Get Intel Filters — Manageability Only Command (Intel Command 0x03, Filter Parameter 0x0F)

This command retrieves the MNGONLY register. The MNGONLY register controls whether pass-through packets destined to the BMC are also be forwarded to the Host OS.

| Bytes   | Bits                          |       |      |     |
|---------|-------------------------------|-------|------|-----|
|         | 31:24                         | 23:16 | 15:8 | 7:0 |
| 0...3   | NC-SI Header                  |       |      |     |
| 4...7   |                               |       |      |     |
| 8...11  |                               |       |      |     |
| 12...15 |                               |       |      |     |
| 16...19 | Manufacturer ID (Intel 0x157) |       |      |     |
| 20...21 | 0x03                          | 0x0F  |      |     |

### 11.6.3.8.2.1 Get Intel Filters — Manageability Only Response (Intel Command 0x03, Filter Parameter 0x0F)

The *MNGONLY* register structure is described in [Table 11-4](#).

|         | Bits                          |       |                             |     |
|---------|-------------------------------|-------|-----------------------------|-----|
| Bytes   | 31:24                         | 23:16 | 15:8                        | 7:0 |
| 0...3   | NC-SI Header                  |       |                             |     |
| 4...7   |                               |       |                             |     |
| 8...11  |                               |       |                             |     |
| 12...15 |                               |       |                             |     |
| 16...19 | Response Code                 |       | Reason Code                 |     |
| 20...23 | Manufacturer ID (Intel 0x157) |       |                             |     |
| 24...27 | 0x03                          | 0x0F  | Manageability to Host (3-2) |     |
| 28...29 | Manageability to Host (1-0)   |       |                             |     |

### 11.6.3.8.3 Get Intel Filters — Flex Filter 0 Enable Mask and Length Command (Intel Command 0x03, Filter Parameter 0x10)

The following command retrieves the Intel flex filters mask and length. See [Section 11.3.3.5](#) for details of the values returned by this command.

| Bits    |                               |       |      |     |
|---------|-------------------------------|-------|------|-----|
| Bytes   | 31:24                         | 23:16 | 15:8 | 7:0 |
| 0...3   | NC-SI Header                  |       |      |     |
| 4...7   |                               |       |      |     |
| 8...11  |                               |       |      |     |
| 12...15 |                               |       |      |     |
| 16...19 | Manufacturer ID (Intel 0x157) |       |      |     |
| 20...21 | 0x03                          | 0x10  |      |     |

### 11.6.3.8.3.1 Get Intel Filters — Flex Filter 0 Enable Mask and Length Response (Intel Command 0x03, Filter Parameter 0x10)

|         | Bits                          |              |             |             |
|---------|-------------------------------|--------------|-------------|-------------|
| Bytes   | 31:24                         | 23:16        | 15:8        | 7:0         |
| 0...3   | NC-SI Header                  |              |             |             |
| 4...7   |                               |              |             |             |
| 8...11  |                               |              |             |             |
| 12...15 |                               |              |             |             |
| 16...19 | Response Code                 |              | Reason Code |             |
| 20...23 | Manufacturer ID (Intel 0x157) |              |             |             |
| 24...27 | 0x03                          | 0x10         | Mask Byte 1 | Mask Byte 2 |
| 28...31 | ...                           | ...          | ...         | ...         |
| 32...35 | ...                           | ...          | ...         | ...         |
| 36...39 | ...                           | ...          | ...         | ...         |
| 40...43 | ...                           | Mask Byte 16 | Reserved    | Reserved    |
| 44      | Flexible Filter Length        |              |             |             |

### 11.6.3.8.4 Get Intel Filters — Flex Filter 0 Data Command (Intel Command 0x03, Filter Parameter 0x11)

The following command retrieves the Intel flex filters data.

| Bytes   | Bits                          |       |                         |     |
|---------|-------------------------------|-------|-------------------------|-----|
|         | 31:24                         | 23:16 | 15:8                    | 7:0 |
| 0...3   | NC-SI Header                  |       |                         |     |
| 4...7   |                               |       |                         |     |
| 8...11  |                               |       |                         |     |
| 12...15 |                               |       |                         |     |
| 16...19 | Manufacturer ID (Intel 0x157) |       |                         |     |
| 20...21 | 0x03                          | 0x11  | Filter Data Group 0...4 |     |

The Filter Data Group parameter defines which bytes of the Flex filter are returned by this command:

**Table 11-34. Filter Data Group**

| Code | Bytes Returned |
|------|----------------|
| 0x0  | Bytes 0–29     |
| 0x1  | Bytes 30–59    |
| 0x2  | Bytes 60–89    |
| 0x3  | Bytes 90–119   |
| 0x4  | Bytes 120–127  |

#### 11.6.3.8.4.1 Get Intel Filters — Flex Filter 0 Data Response (Intel Command 0x03, Filter Parameter 0x11)

|         | Bits                          |               |                     |               |
|---------|-------------------------------|---------------|---------------------|---------------|
| Bytes   | 31:24                         | 23:16         | 15:8                | 7:0           |
| 0...3   | NC-SI Header                  |               |                     |               |
| 4...7   |                               |               |                     |               |
| 8...11  |                               |               |                     |               |
| 12...15 |                               |               |                     |               |
| 16...19 | Response Code                 |               | Reason Code         |               |
| 20...23 | Manufacturer ID (Intel 0x157) |               |                     |               |
| 24...   | 0x03                          | 0x11          | Filter Group Number | Filter Data 1 |
|         | ...                           | Filter Data N |                     |               |

#### 11.6.3.8.5 Get Intel Filters — Flex TCP/UDP Port Filter Command (Intel Command 0x03, Filter Parameter 0x63)

| Bytes   | Bits                          |       |                      |     |
|---------|-------------------------------|-------|----------------------|-----|
|         | 31:24                         | 23:16 | 15:8                 | 7:0 |
| 0...3   | NC-SI Header                  |       |                      |     |
| 4...7   |                               |       |                      |     |
| 8...11  |                               |       |                      |     |
| 12...15 |                               |       |                      |     |
| 16...19 | Manufacturer ID (Intel 0x157) |       |                      |     |
| 20...22 | 0x03                          | 0x63  | TCP/UDP Filter Index |     |

Filter index range: 0x0...0xA.

### 11.6.3.8.5.1 Get Intel Filters — Flex TCP/UDP Port Filter Response (Intel Command 0x03, Filter Parameter 0x63)

|         | Bits                          |       |                      |                  |
|---------|-------------------------------|-------|----------------------|------------------|
| Bytes   | 31:24                         | 23:16 | 15:8                 | 7:0              |
| 0...3   | NC-SI Header                  |       |                      |                  |
| 4...7   |                               |       |                      |                  |
| 8...11  |                               |       |                      |                  |
| 12...15 |                               |       |                      |                  |
| 16...19 | Response Code                 |       | Reason Code          |                  |
| 20...23 | Manufacturer ID (Intel 0x157) |       |                      |                  |
| 24...27 | 0x03                          | 0x63  | TCP/UDP Filter Index | TCP/UDP Port (1) |
| 28      | TCP/UDP Port (0)              |       |                      |                  |

Filter index range: 0x0...0xA.

### 11.6.3.8.6 Get Intel Filters — IPv4 Filter Command (Intel Command 0x03, Filter Parameter 0x64)

| Bytes   | Bits                          |       |                   |     |
|---------|-------------------------------|-------|-------------------|-----|
|         | 31:24                         | 23:16 | 15:8              | 7:0 |
| 0...3   | NC-SI Header                  |       |                   |     |
| 4...7   |                               |       |                   |     |
| 8...11  |                               |       |                   |     |
| 12...15 |                               |       |                   |     |
| 16...19 | Manufacturer ID (Intel 0x157) |       |                   |     |
| 20...22 | 0x03                          | 0x64  | IPv4 Filter Index |     |

**Note:** The filters index range can vary according to the IPv4/IPv6 mode setting in the Filters Control command.

IPv4 Mode: Filter index range: 0x0...0x3.

IPv6 Mode: This command should not be used in IPv6 mode.

### 11.6.3.8.6.1 Get Intel Filters — IPv4 Filter Response (Intel Command 0x03, Filter Parameter 0x64)

|         | Bits                          |       |                   |                  |
|---------|-------------------------------|-------|-------------------|------------------|
| Bytes   | 31:24                         | 23:16 | 15:8              | 7:0              |
| 0...3   | NC-SI Header                  |       |                   |                  |
| 4...7   |                               |       |                   |                  |
| 8...11  |                               |       |                   |                  |
| 12...15 |                               |       |                   |                  |
| 16...19 | Response Code                 |       | Reason Code       |                  |
| 20...23 | Manufacturer ID (Intel 0x157) |       |                   |                  |
| 24...27 | 0x03                          | 0x64  | IPv4 Filter Index | IPv4 Address (3) |
| 28...29 | IPv4 Address (2-0)            |       |                   |                  |

### 11.6.3.8.7 Get Intel Filters — IPv6 Filter Command (Intel Command 0x03, Filter Parameter 0x65)

| Bytes   | Bits                          |       |                   |     |
|---------|-------------------------------|-------|-------------------|-----|
|         | 31:24                         | 23:16 | 15:8              | 7:0 |
| 0...3   | NC-SI Header                  |       |                   |     |
| 4...7   |                               |       |                   |     |
| 8...11  |                               |       |                   |     |
| 12...15 |                               |       |                   |     |
| 16...19 | Manufacturer ID (Intel 0x157) |       |                   |     |
| 20...22 | 0x03                          | 0x65  | IPv6 Filter Index |     |

**Note:** The filters index range can vary according to the IPv4/IPv6 mode setting in the Filters Control command

IPv4 Mode: Filter index range: 0x0...0x2.

IPv6 Mode: Filter index range: 0x0...0x3.

### 11.6.3.8.7.1 Get Intel Filters — IPv6 Filter Response Intel Command 0x03, Filter Parameter 0x65)

|         | Bits                          |       |                            |                             |
|---------|-------------------------------|-------|----------------------------|-----------------------------|
| Bytes   | 31:24                         | 23:16 | 15:8                       | 7:0                         |
| 0...3   | NC-SI Header                  |       |                            |                             |
| 4...7   |                               |       |                            |                             |
| 8...11  |                               |       |                            |                             |
| 12...15 |                               |       |                            |                             |
| 16...19 | Response Code                 |       | Reason Code                |                             |
| 20...23 | Manufacturer ID (Intel 0x157) |       |                            |                             |
| 24...27 | 0x03                          | 0x65  | IPv6 Filter Index          | IPv6 Address (MSB, Byte 16) |
| 28...31 | ...                           | ...   | ...                        | ...                         |
| 32...35 | ...                           | ...   | ...                        | ...                         |
| 36...39 | ...                           | ...   | ...                        | ...                         |
| 40...42 | ...                           | ...   | IPv6 Address (LSB, Byte 0) |                             |

### 11.6.3.8.8 Get Intel Filters - EtherType Filter Command (Intel Command 0x03, Filter Parameter 0x67)

| Bytes   | Bits                          |       |                        |     |
|---------|-------------------------------|-------|------------------------|-----|
|         | 31:24                         | 23:16 | 15:8                   | 7:0 |
| 0...3   | NC-SI Header                  |       |                        |     |
| 4...7   |                               |       |                        |     |
| 8...11  |                               |       |                        |     |
| 12...15 |                               |       |                        |     |
| 16...19 | Manufacturer ID (Intel 0x157) |       |                        |     |
| 20...22 | 0x03                          | 0x67  | EtherType Filter Index |     |

Valid indices: 0...3

### 11.6.3.8.8.1 Get Intel Filters - EtherType Filter Response (Intel Command 0x03, Filter Parameter 0x67)

|         | Bits                          |       |                        |                      |
|---------|-------------------------------|-------|------------------------|----------------------|
| Bytes   | 31:24                         | 23:16 | 15:8                   | 7:0                  |
| 0...3   | NC-SI Header                  |       |                        |                      |
| 4...7   |                               |       |                        |                      |
| 8...11  |                               |       |                        |                      |
| 12...15 |                               |       |                        |                      |
| 16...19 | Response Code                 |       | Reason Code            |                      |
| 20...23 | Manufacturer ID (Intel 0x157) |       |                        |                      |
| 24...27 | 0x03                          | 0x67  | EtherType Filter Index | EtherType Filter MSB |
| 28...30 | ...                           | ...   | EtherType Filter LSB   |                      |

If the Ethertype filter Index is larger than 3, a command failed Response Code is returned with Invalid Intel Parameter Number reason (0x5082).

### 11.6.3.8.9 Get Intel Filters – Packet Addition Extended Decision Filter Command (Intel Command 0x03, Filter Parameter 0x68)

This command allows the BMC to retrieve the Extended Decision Filter.

| Bytes   | Bits                          |       |                                |     |
|---------|-------------------------------|-------|--------------------------------|-----|
|         | 31:24                         | 23:16 | 15:8                           | 7:0 |
| 0...3   | NC-SI Header                  |       |                                |     |
| 4...7   |                               |       |                                |     |
| 8...11  |                               |       |                                |     |
| 12...15 |                               |       |                                |     |
| 16...19 | Manufacturer ID (Intel 0x157) |       |                                |     |
| 20...22 | 0x03                          | 0x68  | Extended Decision Filter Index |     |

### 11.6.3.8.9.1 Get Intel Filters – Packet Addition Extended Decision Filter Response (Intel Command 0x03, Filter Parameter 0x68)

|         | Bits                          |       |                       |                       |
|---------|-------------------------------|-------|-----------------------|-----------------------|
| Bytes   | 31:24                         | 23:16 | 15:8                  | 7:0                   |
| 0...3   | NC-SI Header                  |       |                       |                       |
| 4...7   |                               |       |                       |                       |
| 8...11  |                               |       |                       |                       |
| 12...15 |                               |       |                       |                       |
| 16...19 | Response Code                 |       | Reason Code           |                       |
| 20...23 | Manufacturer ID (Intel 0x157) |       |                       |                       |
| 24...27 | 0x03                          | 0x68  | Decision Filter Index | Decision Filter 1 MSB |
| 28...31 | ...                           | ...   | Decision Filter 1 LSB | Decision Filter 0 MSB |
| 32...34 | ...                           | ...   | Decision Filter 0 LSB |                       |

Where Decision Filter 0 & Decision Filter 1 have the structure as detailed in the respective “Set” commands.

If the Extended Decision Filter Index is bigger than 4, a command failed Response Code is returned with Invalid Intel Parameter Number reason (0x5082).

## 11.6.3.9 Set Intel Packet Reduction Filters Formats

The non extended commands (are obsolete. The extended commands (Section 11.6.3.9.2 to Section 11.6.3.9.4.1) should be used instead

### 11.6.3.9.1 Set Intel Packet Reduction Filters Command (Intel Command 0x04)

| Bytes   | Bits                          |                        |                       |     |
|---------|-------------------------------|------------------------|-----------------------|-----|
|         | 31:24                         | 23:16                  | 15:8                  | 7:0 |
| 0...3   | NC-SI Header                  |                        |                       |     |
| 4...7   |                               |                        |                       |     |
| 8...11  |                               |                        |                       |     |
| 12...15 |                               |                        |                       |     |
| 16...19 | Manufacturer ID (Intel 0x157) |                        |                       |     |
| 20...23 | 0x04                          | Packet Reduction Index | Packet Reduction Data |     |

**Note:** It is advised that the BMC only uses the Extended Packet Reduction commands.

The *Packet Reduction Data* field has the following structure:

**Table 11-35. Packet Reduction Field Description**

| Bit(s) | Name               | Description                                                                         |
|--------|--------------------|-------------------------------------------------------------------------------------|
| 12:0   | Reserved           | Reserved.                                                                           |
| 16:13  | IPv4 Address (AND) | If set, packets must match IPv4 filter 0 to 3, respectively.                        |
| 20:17  | IPv6 Address (AND) | If set, packets must match IPv4 filter 0 to 3, respectively.                        |
| 27:21  | Reserved           | Reserved.                                                                           |
| 28     | ARP Response (OR)  | If set, packets can pass if match the ARP response filter or a different OR filter. |
| 29     | Reserved           | Reserved.                                                                           |
| 30     | Port 0x298         | If set, packets can pass if match a fixed TCP/UDP port 0x298 filter.                |
| 31     | Port 0x26F         | If set, packets can pass if match a fixed TCP/UDP port 0x26F filter.                |

**Table 11-36. Extended Packet Reduction Field Description**

| Bit(s) | Name                 | Description                                                                           |
|--------|----------------------|---------------------------------------------------------------------------------------|
| 3:0    | Ethertype 0 -3 (AND) | If set, packets must match the Ethertype filter 0 to 3, respectively.                 |
| 7:4    | Ethertype 0-3 (OR)   | If set, packets can pass if match the Ethertype filter 0 to 3, respectively.          |
| 15:12  | Reserved             | Reserved.                                                                             |
| 8:18   | Flex port 10:0 (OR)  | If set, packets can pass if match the TCP/UDP Port filter 10:0.                       |
| 23:19  | Reserved             |                                                                                       |
| 24     | Flex TCO (OR)        | If set, packets can pass if match the Flex 128 TCO filter.                            |
| 28:25  | Reserved             |                                                                                       |
| 29     | MLD (OR)             | If set, packets must also match one of the MLD ICMPv6 types or a different OR filter. |
| 31:30  | Reserved             | Reserved.                                                                             |

The filtering is divided into two decisions:

- Bit 20:13 in [Table 11-35](#) and Bits 3:2 in [Table 11-36](#) works in an AND manner; it must be true for a packet to pass (if was set).
- Bits 28 in [Table 11-35](#) and Bits 24:10 in [Table 11-36](#) work in an OR manner; at least one of them must be true for a packet to pass (if any were set).

#### 11.6.3.9.1.1 Set Intel Packet Reduction Filters Response (Intel Command 0x04)

|         | Bits                          |                        |             |     |
|---------|-------------------------------|------------------------|-------------|-----|
| Bytes   | 31:24                         | 23:16                  | 15:8        | 7:0 |
| 0...3   | NC-SI Header                  |                        |             |     |
| 4...7   |                               |                        |             |     |
| 8...11  |                               |                        |             |     |
| 12...15 |                               |                        |             |     |
| 16...19 | Response Code                 |                        | Reason Code |     |
| 20...23 | Manufacturer ID (Intel 0x157) |                        |             |     |
| 24...   | 0x04                          | Packet Reduction Index |             |     |

### 11.6.3.9.2 Set Extended Unicast Packet Reduction Command (Intel Command 0x04, Reduction Filter Index 0x10)

This command has the following format:

| Bits    |                               |                                       |                                       |     |
|---------|-------------------------------|---------------------------------------|---------------------------------------|-----|
| Bytes   | 31:24                         | 23:16                                 | 15:8                                  | 7:0 |
| 0...3   | NC-SI Header                  |                                       |                                       |     |
| 4...7   |                               |                                       |                                       |     |
| 8...11  |                               |                                       |                                       |     |
| 12...15 |                               |                                       |                                       |     |
| 16...19 | Manufacturer ID (Intel 0x157) |                                       |                                       |     |
| 20...23 | 0x04                          | 0x10                                  | Extended Unicast Reduction Filter MSB | ... |
| 24...27 | ...                           | Extended Unicast Reduction Filter LSB | Unicast Reduction Filter MSB          | ... |
| 28...29 | ...                           | Unicast Reduction Filter LSB          |                                       |     |

This command overwrites any previously stored value.

**Note:** See [Table 11-35](#) and [Table 11-36](#) for description of the Unicast Extended Packet Reduction format.

#### 11.6.3.9.2.1 Set Extended Unicast Packet Reduction Response (Intel Command 0x04, Reduction Filter Index 0x10)

|         | Bits                          |       |             |     |
|---------|-------------------------------|-------|-------------|-----|
| Bytes   | 31:24                         | 23:16 | 15:8        | 7:0 |
| 0...3   | NC-SI Header                  |       |             |     |
| 4...7   |                               |       |             |     |
| 8...11  |                               |       |             |     |
| 12...15 |                               |       |             |     |
| 16...19 | Response Code                 |       | Reason Code |     |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |     |
| 24...25 | 0x04                          | 0x10  |             |     |

### 11.6.3.9.3 Set Extended Multicast Packet Reduction Command (Intel Command 0x04, Reduction Filter Index 0x11)

| Bytes   | Bits                          |                                         |                                         |     |
|---------|-------------------------------|-----------------------------------------|-----------------------------------------|-----|
|         | 31:24                         | 23:16                                   | 15:8                                    | 7:0 |
| 0...3   | NC-SI Header                  |                                         |                                         |     |
| 4...7   |                               |                                         |                                         |     |
| 8...11  |                               |                                         |                                         |     |
| 12...15 |                               |                                         |                                         |     |
| 16...19 | Manufacturer ID (Intel 0x157) |                                         |                                         |     |
| 20...23 | 0x04                          | 0x11                                    | Extended Multicast Reduction Filter MSB | ... |
| 24...27 | ...                           | Extended Multicast Reduction Filter LSB | Multicast Reduction Filter MSB          | ... |
| 28...29 | ...                           | Multicast Reduction Filter LSB          |                                         |     |

**Note:** See [Table 11-35](#) and [Table 11-36](#) for description of the Multicast Extended Packet Reduction format.

This command overwrites any previously stored value.

#### 11.6.3.9.3.1 Set Extended Multicast Packet Reduction Response (Intel Command 0x04, Reduction Filter Index 0x11)

|         | Bits                          |       |             |     |
|---------|-------------------------------|-------|-------------|-----|
| Bytes   | 31:24                         | 23:16 | 15:8        | 7:0 |
| 0...3   | NC-SI Header                  |       |             |     |
| 4...7   |                               |       |             |     |
| 8...11  |                               |       |             |     |
| 12...15 |                               |       |             |     |
| 16...19 | Response Code                 |       | Reason Code |     |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |     |
| 24...25 | 0x04                          | 0x11  |             |     |

#### 11.6.3.9.4 Set Extended Broadcast Packet Reduction Command (Intel Command 0x04, Reduction Filter Index 0x12)

| Bytes   | Bits                          |                                         |                                         |     |
|---------|-------------------------------|-----------------------------------------|-----------------------------------------|-----|
|         | 31:24                         | 23:16                                   | 15:8                                    | 7:0 |
| 0...3   | NC-SI Header                  |                                         |                                         |     |
| 4...7   |                               |                                         |                                         |     |
| 8...11  |                               |                                         |                                         |     |
| 12...15 |                               |                                         |                                         |     |
| 16...19 | Manufacturer ID (Intel 0x157) |                                         |                                         |     |
| 20...23 | 0x04                          | 0x12                                    | Extended Broadcast Reduction Filter MSB | ... |
| 24...27 | ...                           | Extended Broadcast Reduction Filter LSB | Broadcast Reduction Filter MSB          | ... |
| 28...29 | ...                           | Broadcast Reduction Filter LSB          |                                         |     |

**Note:** See Table 11-35 and Table 11-36 for description of the Broadcast Extended Packet Reduction format.

This command overwrites any previously stored value.

##### 11.6.3.9.4.1 Set Extended Broadcast Packet Reduction Response (Intel Command 0x04, Reduction Filter Index 0x12)

|         | Bits                          |       |             |     |
|---------|-------------------------------|-------|-------------|-----|
| Bytes   | 31:24                         | 23:16 | 15:8        | 7:0 |
| 0...3   | NC-SI Header                  |       |             |     |
| 4...7   |                               |       |             |     |
| 8...11  |                               |       |             |     |
| 12...15 |                               |       |             |     |
| 16...19 | Response Code                 |       | Reason Code |     |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |     |
| 24...25 | 0x04                          | 0x12  |             |     |

### 11.6.3.10 Get Intel Packet Reduction Filters Formats

**Note:** The non extended commands are not supported anymore. Use the extended commands (Section 11.6.3.10.1 to Section 11.6.3.10.3.1) instead

#### 11.6.3.10.1 Get Extended Unicast Packet Reduction Command (Intel Command 0x05, Reduction Filter Index 0x10)

| Bytes   | Bits                          |       |      |     |
|---------|-------------------------------|-------|------|-----|
|         | 31:24                         | 23:16 | 15:8 | 7:0 |
| 0...3   | NC-SI Header                  |       |      |     |
| 4...7   |                               |       |      |     |
| 8...11  |                               |       |      |     |
| 12...15 |                               |       |      |     |
| 16...19 | Manufacturer ID (Intel 0x157) |       |      |     |
| 20...21 | 0x05                          | 0x10  |      |     |

#### 11.6.3.10.1.1 Get Extended Unicast Packet Reduction Response (Intel Command 0x05, Reduction Filter Index 0x10)

|         | Bits                                    |       |                                         |     |
|---------|-----------------------------------------|-------|-----------------------------------------|-----|
| Bytes   | 31:24                                   | 23:16 | 15:8                                    | 7:0 |
| 0...3   | NC-SI Header                            |       |                                         |     |
| 4...7   |                                         |       |                                         |     |
| 8...11  |                                         |       |                                         |     |
| 12...15 |                                         |       |                                         |     |
| 16...19 | Response Code                           |       | Reason Code                             |     |
| 20...23 | Manufacturer ID (Intel 0x157)           |       |                                         |     |
| 24...27 | 0x05                                    | 0x00  | Extended Unicast Packet Reduction (3-2) |     |
| 28...29 | Extended Unicast Packet Reduction (1-0) |       | Unicast Packet Reduction (3-2)          |     |
| 30...31 | Unicast Packet Reduction (1-0)          |       |                                         |     |

### 11.6.3.10.2 Get Extended Multicast Packet Reduction Command (Intel Command 0x05, Reduction Filter Index 0x11)

| Bytes   | Bits                          |       |      |     |
|---------|-------------------------------|-------|------|-----|
|         | 31:24                         | 23:16 | 15:8 | 7:0 |
| 0...3   | NC-SI Header                  |       |      |     |
| 4...7   |                               |       |      |     |
| 8...11  |                               |       |      |     |
| 12...15 |                               |       |      |     |
| 16...19 | Manufacturer ID (Intel 0x157) |       |      |     |
| 20...21 | 0x05                          | 0x11  |      |     |

#### 11.6.3.10.2.1 Get Extended Multicast Packet Reduction Response (Intel Command 0x05, Reduction Filter Index 0x11)

|         | Bits                                      |       |                                           |     |
|---------|-------------------------------------------|-------|-------------------------------------------|-----|
| Bytes   | 31:24                                     | 23:16 | 15:8                                      | 7:0 |
| 0...3   | NC-SI Header                              |       |                                           |     |
| 4...7   |                                           |       |                                           |     |
| 8...11  |                                           |       |                                           |     |
| 12...15 |                                           |       |                                           |     |
| 16...19 | Response Code                             |       | Reason Code                               |     |
| 20...23 | Manufacturer ID (Intel 0x157)             |       |                                           |     |
| 24...27 | 0x05                                      | 0x11  | Extended Multicast Packet Reduction (3-2) |     |
| 28...29 | Extended Multicast Packet Reduction (1-0) |       | Multicast Packet Reduction (3-2)          |     |
| 30...31 | Multicast Packet Reduction (1-0)          |       |                                           |     |

### 11.6.3.10.3 Get Extended Broadcast Packet Reduction Command (Intel Command 0x05, Reduction Filter Index 0x12)

| Bytes   | Bits                          |       |      |     |
|---------|-------------------------------|-------|------|-----|
|         | 31:24                         | 23:16 | 15:8 | 7:0 |
| 0...3   | NC-SI Header                  |       |      |     |
| 4...7   |                               |       |      |     |
| 8...11  |                               |       |      |     |
| 12...15 |                               |       |      |     |
| 16...19 | Manufacturer ID (Intel 0x157) |       |      |     |
| 20...21 | 0x05                          | 0x12  |      |     |

### 11.6.3.10.3.1 Get Extended Broadcast Packet Reduction Response (Intel Command 0x05, Reduction Filter Index 0x12)

|         | Bits                                      |       |                                           |     |
|---------|-------------------------------------------|-------|-------------------------------------------|-----|
| Bytes   | 31:24                                     | 23:16 | 15:8                                      | 7:0 |
| 0...3   | NC-SI Header                              |       |                                           |     |
| 4...7   |                                           |       |                                           |     |
| 8...11  |                                           |       |                                           |     |
| 12...15 |                                           |       |                                           |     |

## 11.6.3.11 System MAC Address

### 11.6.3.11.1 Get System MAC Address Command (Intel Command 0x06)

To support a system configuration that requires the NC to hold the MAC Address for the BMC (such as shared MAC Address mode), the following command is provided to enable the BMC to query the NC for a valid MAC Address.

The NC must return the system MAC Addresses. The BMC should use the returned MAC Addressing as a shared MAC Address by setting it using the Set MAC Address command as defined in NC-SI 1.0.

It is also recommended that the BMC use packet reduction and Manageability-to-Host command to set the proper filtering method.

| Bytes   | Bits                          |       |      |     |
|---------|-------------------------------|-------|------|-----|
|         | 31:24                         | 23:16 | 15:8 | 7:0 |
| 0...3   | NC-SI Header                  |       |      |     |
| 4...7   |                               |       |      |     |
| 8...11  |                               |       |      |     |
| 12...15 |                               |       |      |     |
| 16...19 | Manufacturer ID (Intel 0x157) |       |      |     |
| 20      | 0x06                          |       |      |     |

### 11.6.3.11.2 Get System MAC Address Response (Intel Command 0x06)

| 12...15 |                               |       |                               |     |
| 16...19 | Response Code                 |       | Reason Code                   |     |
| 20...23 | Manufacturer ID (Intel 0x157) |       |                               |     |
| 24...26 | 0x21                          | 0x00  | Intel Management Control<br>1 |     |

### 11.6.3.14 TCO Reset

Depending on the bit set in the TCO mode field this command causes the X550 to perform either:

#### 1. TCO Reset

- The Force TCO reset clears the data-path (Rx/Tx) of the X550 to enable the BMC to transmit/receive packets through the X550.
- If the BMC has detected that the OS is hung and has blocked the Rx/Tx path The Force TCO reset clears the data-path (Rx/Tx) of the Network Controller to enable the BMC to transmit/receive packets through the Network Controller.
- When this command is issued to a channel in a package, it applies only to the specific channel.
- After successfully performing the command, the Network Controller considers Force TCO command as an indication that the OS is hung, and clears the DRV\_LOAD flag (disable the driver). If TCO reset is disabled in NVM, the X550 does not reset the data-path and notifies BMC on successful completion.

#### 2. TCO isolate

- If TCO isolate is enabled in the NVM (See [Section 6.5.2.2](#)). The TCO Isolate command disables PCIe write operations to the LAN port.
- If TCO Isolate is disabled in NVM, the X550 does not execute the command but sends a response to the BMC with successful completion.
- Following TCO Isolate management isolates the function related to the port on which the command was received.

#### 3. Firmware Reset

- This command causes re-initialization of all the manageability functions and re-load of manageability related NVM words.
- When the BMC has loaded new management-related NVM image, the Firmware Reset command loads management-related NVM information without the need to power down the system.
- This command is issued to the package and affects all channels. After the firmware reset the FW Semaphore register (FWSM) is re-initialized.

**Note:** TCO isolate and force TCO affects only the channel (port) that the command was issued to. Following firmware reset, BMC must re-initialize all ports. Only one of the fields should be set in a given command. Setting more than one field may yield unexpected results.

### 11.6.3.14.1 Perform Intel TCO Reset Command (Intel Command 0x22)

| Bytes   | Bits                          |          |      |     |
|---------|-------------------------------|----------|------|-----|
|         | 31:24                         | 23:16    | 15:8 | 7:0 |
| 0...3   | NC-SI Header                  |          |      |     |
| 4...7   |                               |          |      |     |
| 8...11  |                               |          |      |     |
| 12...15 |                               |          |      |     |
| 16...19 | Manufacturer ID (Intel 0x157) |          |      |     |
| 20      | 0x22                          | TCO Mode |      |     |

Where TCO Mode is:

| Field                       | Bit(s) | Description                                                                                                                                                                                                                                        |
|-----------------------------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DO_TCO_RST                  | 0      | Perform TCO Reset.<br>0b = Do nothing.<br>1b = Perform TCO reset.                                                                                                                                                                                  |
| DO_TCO_ISOLATE <sup>1</sup> | 1      | Do TCO Isolate<br>0b = Enable PCIe write access to LAN port.<br>1b = Isolate Host PCIe write operation to the port<br><b>Note:</b> Should be used for debug only.                                                                                  |
| RESET_MGMT                  | 2      | Reset manageability; re-load manageability NVM words.<br>0b = Do nothing.<br>1b = Issue firmware reset to manageability.<br>Setting this bit generates a one-time firmware reset. Following the reset, management related data from NVM is loaded. |
| Reserved                    | 7:3    | Reserved (set to 0x00).                                                                                                                                                                                                                            |

**Note:** For compatibility, the TCO reset command without the TCO Mode parameter is accepted (TCO reset is performed).

1. TCO Isolate Host Write operation enabled in NVM.

### 11.6.3.14.2 Perform Intel TCO Reset Response (Intel Command 0x22)

When a firmware reset is requested (TCO Mode = RESET\_MGMT), there is no response, as the NC goes to Initial State as part of the command execution.

|         | Bits                          |       |             |     |

| 24...26 | 0x22                          |       |             |     |

### 11.6.3.15 Checksum Offloading

This command enables the checksum offloading filters in the NC.

When enabled, these filters block any packets that did not pass IP, UDP or TCP checksum from being forwarded to the BMC.

#### 11.6.3.15.1 Enable Checksum Offloading Command (Intel Command 0x23)

| Bytes   | Bits                          |       |      |     |
|---------|-------------------------------|-------|------|-----|
|         | 31:24                         | 23:16 | 15:8 | 7:0 |
| 0...3   | NC-SI Header                  |       |      |     |
| 4...7   |                               |       |      |     |
| 8...11  |                               |       |      |     |
| 12...15 |                               |       |      |     |
| 16...19 | Manufacturer ID (Intel 0x157) |       |      |     |
| 20      | 0x23                          |       |      |     |

### 11.6.3.15.2 Enable Checksum Offloading Response (Intel Command 0x23)

|         | Bits                          |       |             |     |
|---------|-------------------------------|-------|-------------|-----|
| Bytes   | 31:24                         | 23:16 | 15:8        | 7:0 |
| 0...3   | NC-SI Header                  |       |             |     |
| 4...7   |                               |       |             |     |
| 8...11  |                               |       |             |     |
| 12...15 |                               |       |             |     |
| 16...19 | Response Code                 |       | Reason Code |     |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |     |
| 24...26 | 0x23                          |       |             |     |

### 11.6.3.15.3 Disable Checksum Offloading Command (Intel Command 0x24)

| Bytes   | Bits                          |       |      |     |
|---------|-------------------------------|-------|------|-----|
|         | 31:24                         | 23:16 | 15:8 | 7:0 |
| 0...3   | NC-SI Header                  |       |      |     |
| 4...7   |                               |       |      |     |
| 8...11  |                               |       |      |     |
| 12...15 |                               |       |      |     |
| 16...19 | Manufacturer ID (Intel 0x157) |       |      |     |
| 20      | 0x24                          |       |      |     |

### 11.6.3.15.4 Disable Checksum Offloading Response (Intel Command 0x24)

|         | Bits                          |       |             |     |
|---------|-------------------------------|-------|-------------|-----|
| Bytes   | 31:24                         | 23:16 | 15:8        | 7:0 |
| 0...3   | NC-SI Header                  |       |             |     |
| 4...7   |                               |       |             |     |
| 8...11  |                               |       |             |     |
| 12...15 |                               |       |             |     |
| 16...19 | Response Code                 |       | Reason Code |     |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |     |
| 24...26 | 0x24                          |       |             |     |

### 11.6.3.16 OS 2 BMC Configuration

These commands control enabling of the OS 2 BMC flow.

#### 11.6.3.16.1 EnableOS2BMC Flow Command (Intel Command 0x40, Index 0x1)

| Bytes   | Bits                          |       |      |     |
|---------|-------------------------------|-------|------|-----|
|         | 31:24                         | 23:16 | 15:8 | 7:0 |
| 0...3   | NC-SI Header                  |       |      |     |
| 4...7   |                               |       |      |     |
| 8...11  |                               |       |      |     |
| 12...15 |                               |       |      |     |
| 16...19 | Manufacturer ID (Intel 0x157) |       |      |     |
| 20...21 | 0x40                          | 0x01  |      |     |

#### 11.6.3.16.1.1 EnableOS2BMC Flow Response (Intel Command 0x40, Index 0x1)

|         | Bits                          |       |             |     |
|---------|-------------------------------|-------|-------------|-----|
| Bytes   | 31:24                         | 23:16 | 15:8        | 7:0 |
| 0...3   | NC-SI Header                  |       |             |     |
| 4...7   |                               |       |             |     |
| 8...11  |                               |       |             |     |
| 12...15 |                               |       |             |     |
| 16...19 | Response Code                 |       | Reason Code |     |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |     |
| 24...25 | 0x40                          | 0x01  |             |     |

#### 11.6.3.16.2 Enable Network to BMC Flow Command (Intel Command 0x40, Index 0x2)

| Bytes   | Bits                          |       |      |     |
|---------|-------------------------------|-------|------|-----|
|         | 31:24                         | 23:16 | 15:8 | 7:0 |
| 0...3   | NC-SI Header                  |       |      |     |
| 4...7   |                               |       |      |     |
| 8...11  |                               |       |      |     |
| 12...15 |                               |       |      |     |
| 16...19 | Manufacturer ID (Intel 0x157) |       |      |     |
| 20...21 | 0x40                          | 0x02  |      |     |

### 11.6.3.16.2.1 Enable Network to BMC Flow Response (Intel Command 0x40, Index 0x2)

|         | Bits                          |       |             |     |
|---------|-------------------------------|-------|-------------|-----|
| Bytes   | 31:24                         | 23:16 | 15:8        | 7:0 |
| 0...3   | NC-SI Header                  |       |             |     |
| 4...7   |                               |       |             |     |
| 8...11  |                               |       |             |     |
| 12...15 |                               |       |             |     |
| 16...19 | Response Code                 |       | Reason Code |     |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |     |
| 24...25 | 0x40                          | 0x02  |             |     |

### 11.6.3.16.3 Enable Both Host and Network to BMC Flows Command (Intel Command 0x40, Index 0x3)

| Bits    |                               |       |      |     |
|---------|-------------------------------|-------|------|-----|
| Bytes   | 31:24                         | 23:16 | 15:8 | 7:0 |
| 0...3   | NC-SI Header                  |       |      |     |
| 4...7   |                               |       |      |     |
| 8...11  |                               |       |      |     |
| 12...15 |                               |       |      |     |
| 16...19 | Manufacturer ID (Intel 0x157) |       |      |     |
| 20...21 | 0x40                          | 0x03  |      |     |

### 11.6.3.16.3.1 Enable Both Host and Network to BMC Flows Response (Intel Command 0x40, Index 0x3)

|         | Bits                          |       |             |     |
|---------|-------------------------------|-------|-------------|-----|
| Bytes   | 31:24                         | 23:16 | 15:8        | 7:0 |
| 0...3   | NC-SI Header                  |       |             |     |
| 4...7   |                               |       |             |     |
| 8...11  |                               |       |             |     |
| 12...15 |                               |       |             |     |
| 16...19 | Response Code                 |       | Reason Code |     |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |     |
| 24...25 | 0x40                          | 0x03  |             |     |

#### 11.6.3.16.4 Set BMC IP Address Command (Intel Command 0x40, Index 0x4)

This command is used to expose the BMC IP Address to the host.

The IP type entry indicate whether the IP Address is an IPv4 or an IPv6 address:

0 = IPv4

1 = IPv6

2 = No IP Address, then the command should not include an IP Address.

| Bytes   | Bits                                             |                                                  |                                                       |                                                        |
|---------|--------------------------------------------------|--------------------------------------------------|-------------------------------------------------------|--------------------------------------------------------|
|         | 31:24                                            | 23:16                                            | 15:8                                                  | 7:0                                                    |
| 0...3   | NC-SI Header                                     |                                                  |                                                       |                                                        |
| 4...7   |                                                  |                                                  |                                                       |                                                        |
| 8...11  |                                                  |                                                  |                                                       |                                                        |
| 12...15 |                                                  |                                                  |                                                       |                                                        |
| 16...19 | Manufacturer ID (Intel 0x157)                    |                                                  |                                                       |                                                        |

### 11.6.3.18 Get Thermal Sensor Commands (Intel Command 0x4C)

The following tables are used in the various commands:

**Table 11-39. Actions Word Definition**

| Bit(s) | Action                    | Notes                                                                                                                                                                                                                                                                    |
|--------|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0      | Measure only              | Activate the thermal sensor, but no automatic action.                                                                                                                                                                                                                    |
| 1      | Notify BMC                |                                                                                                                                                                                                                                                                          |
| 2      | Power off PHY             |                                                                                                                                                                                                                                                                          |
| 3      | Power on PHY              |                                                                                                                                                                                                                                                                          |
| 4      | Restore Speed             | When the Cancel TS Action command is received, the X550 should set the PHY to its previous state.                                                                                                                                                                        |
| 5      | Set speed to 10 Mb/s Max  | N/A for the X550.                                                                                                                                                                                                                                                        |
| 6      | Set speed to 100 Mb/s Max | These actions set a maximum on the speed and do not force a specific speed. The Set Link command should be used to set a specific link speed.                                                                                                                            |
| 7      | Set speed to 1 Gb/s Max   |                                                                                                                                                                                                                                                                          |
| 8      | Set speed to 10 Gb/s Max  |                                                                                                                                                                                                                                                                          |
| 9      | Indicate on SDP (set)     | The SDP indication is done on SDP_1_1. Indicate on SDP actions are available only if SDP_1_1 is configured as an output in the ESDP register.                                                                                                                            |
| 10     | Indicate on SDP (clear)   |                                                                                                                                                                                                                                                                          |
| 11     | HW autonomous algorithm   | This is used for the X550 and is equivalent to the NVM based mechanism described in <a href="#">Section 5.7.3</a> . When the Threshold set by the MC is crossed, both PHYs are powered down. This action can be canceled by a Cancel all active actions immediate action |
| 12     | Cancel all active actions |                                                                                                                                                                                                                                                                          |
| 13     | Rearm Event               | When the Cancel TS Action command is received, the X550 should set the PHY to its previous state.                                                                                                                                                                        |
| 31:14  | Reserved                  |                                                                                                                                                                                                                                                                          |

**Table 11-40. Unit Types Word Definition**

| Value    | Unit Types     | Notes                                     |
|----------|----------------|-------------------------------------------|
| 0x0      | Generic Number | No specific indication of measured value. |
| 0x1      | Celsius        | Temperature.                              |
| 0x2      | Volts          |                                           |
| 0x3      | rpm            | Speed.                                    |
| 0x4-0xFF | Reserved       | Reserved.                                 |

11.6.3.18.1 Threshold and Hysteresis

Each threshold event includes a direction. For example, a thermal event with a threshold of 100 °C and an “up” direction is defined as the temperature crossing from less than 100 °C to more than 100 °C.

For each threshold an hysteresis may be defined. This hysteresis direction is opposite to the threshold direction. If in the previous example, an hysteresis of 10 °C is defined, it is activated when the temperature crosses from more than 90 °C to less than 90 °C.

Figure 11-8 describes the thresholds and hysteresis modes and the actions activated for each of them.

Figure 11-8. Thresholds, Hysteresis and Actions

**Note:** As there are no low thresholds in the X550, there is no support for thresholds.

11.6.3.18.2 Get Thermal Sensor Capabilities Command (Intel Command 0x4C, Index 0x0)

This command requests the thermal sensor capabilities supported by this device.

| Bits    |                               |       |      |     |
|---------|-------------------------------|-------|------|-----|
| Bytes   | 31:24                         | 23:16 | 15:8 | 7:0 |
| 0...3   | NC-SI Header                  |       |      |     |
| 4...7   |                               |       |      |     |
| 8...11  |                               |       |      |     |
| 12...15 |                               |       |      |     |
| 16...19 | Manufacturer ID (Intel 0x157) |       |      |     |
| 20...21 | 0x4C                          | 0x00  |      |     |

### 11.6.3.18.2.1 Get Thermal Sensor Capabilities Response (Intel Command 0x4C, Index 0x0)

|         | Bits                                        |       |             |                |
|---------|---------------------------------------------|-------|-------------|----------------|
| Bytes   | 31:24                                       | 23:16 | 15:8        | 7:0            |
| 0...3   | NC-SI Header                                |       |             |                |
| 4...7   |                                             |       |             |                |
| 8...11  |                                             |       |             |                |
| 12...15 |                                             |       |             |                |
| 16...19 | Response Code                               |       | Reason Code |                |
| 20...23 | Manufacturer ID (Intel 0x157)               |       |             |                |
| 24...27 | 0x4C                                        | 0x0   | Version     | Unit Types     |
| 28...31 | Number of Thresholds                        |       | Accuracy    | Max hysteresis |
| 32...35 | M                                           | B     | K1          | K2             |
| 36...39 | Available actions - "High going" thresholds |       |             |                |
| 40...43 | Available actions - "Low going" thresholds  |       |             |                |

- Version should always be 1.
- Unit Types = 1 - Temperature reported in Celsius.
- Accuracy describes the accuracy of the reported measurements is as follows:
  - 7:4: Max deviation of actual value above measurement in "unit types" = 3 °C
  - 3:0: Max deviation of actual value below measurement in "unit types" = 3 °C
- Number of thresholds describes the number of up and down thresholds as follows:
  - 15:12: Reserved
  - 11:8: Max Number of mixed thresholds = 0
  - 7:4: Max number of up thresholds = 1
  - 3:0: Max number of down thresholds = 0
- Available Actions "High going" thresholds — Describes the actions that can be activated by the device as described in [Table 11-39](#) when a high going threshold is crossed. The X550 supports Measure Only, Notify BMC, Indicate on SDP (set), Set speed to 100 Mb/s Max, Set speed to 1 GbE Max, and HW autonomous actions.
- Available Actions "Low going" thresholds — Describes the actions that can be activated by the device as described in [Table 11-39](#) when a low going threshold is crossed. The X550 does not support low going thresholds.
- Available Actions "Immediate" — Describes the actions that can be activated by the device as described in [Table 11-39](#). The X550 supports Reset Thermal Sensor, Cancel all active actions, and measure-only actions.
- M = 1; B = 0, K1 = K2 = 0 — The assumption is that the thermal sensor in the X550 is the readable value.
- T<sub>junction-Max</sub> — The maximal junction temperature supported in X550 is 105 °C.

**Note:** This formula is compliant with the definition of section 36.3 “Sensor Reading Conversion Formula” in IPMI 2.0

### 11.6.3.18.3 Get Thermal Sensor Configuration Command (Intel Command 0x4C, Index 0x1)

This command requests the thermal sensor configuration for threshold “Index” in direction “Direction”.

| Bytes   | Bits                          |       |       |     |
|---------|-------------------------------|-------|-------|-----|
|         | 31:24                         | 23:16 | 15:8  | 7:0 |
| 0...3   | NC-SI Header                  |       |       |     |
| 4...7   |                               |       |       |     |
| 8...11  |                               |       |       |     |
| 12...15 |                               |       |       |     |
| 16...19 | Manufacturer ID (Intel 0x157) |       |       |     |
| 20...22 | 0x4C                          | 0x01  | Index |     |

**Note:** If Index points to a non valid threshold as described in the Get Thermal Sensor Capabilities Response, the command fails with an Invalid Parameter reason.

#### 11.6.3.18.3.1 Get Thermal Sensor Configuration Response (Intel Command 0x4C, Index 0x1)

|         | Bits                          |                            |             |               |
|---------|-------------------------------|----------------------------|-------------|---------------|
| Bytes   | 31:24                         | 23:16                      | 15:8        | 7:0           |
| 0...3   | NC-SI Header                  |                            |             |               |
| 4...7   |                               |                            |             |               |
| 8...11  |                               |                            |             |               |
| 12...15 |                               |                            |             |               |
| 16...19 | Response Code                 |                            | Reason Code |               |
| 20...23 | Manufacturer ID (Intel 0x157) |                            |             |               |
| 24...27 | 0x4C                          | 0x1                        | Index       | Threshold (1) |
| 28...31 | Threshold(0)                  | Actions “Going High” (3-1) |             |               |
| 32...35 | Actions “Going High” (0)      | Actions “Going Low” (3-1)  |             |               |
| 36...38 | Actions “Going Low” (0)       | Direction                  | Hysteresis  |               |

The threshold and the Hysteresis are measured in “unit types”.

The *Actions Going High* field describes the actions to activate upon crossing of the threshold for “Going High” thresholds or when crossing the hysteresis for “Going Low” thresholds according to [Table 11-39](#).

The *Actions Going Low* field describes the actions to activate upon crossing of the threshold for “Going Low” thresholds or when crossing the hysteresis for “Going High” thresholds according to [Table 11-39](#).

Direction is encoded as follows:

- 0 = High Going
- 1 = Low Going

#### 11.6.3.18.4 Get Thermal Sensor Status Command (Intel Command 0x4C, Index 0x2)

This command requests the current status of the Thermal sensor.

| Bytes   | Bits                          |       |      |     |
|---------|-------------------------------|-------|------|-----|
|         | 31:24                         | 23:16 | 15:8 | 7:0 |
| 0...3   | NC-SI Header                  |       |      |     |
| 4...7   |                               |       |      |     |
| 8...11  |                               |       |      |     |
| 12...15 |                               |       |      |     |
| 16...19 | Manufacturer ID (Intel 0x157) |       |      |     |
| 20...21 | 0x4C                          | 0x02  |      |     |

#### 11.6.3.18.4.1 Get Thermal Sensor Status Response (Intel Command 0x4C, Index 0x2)

|         | Bits                          |       |                |     |
|---------|-------------------------------|-------|----------------|-----|
| Bytes   | 31:24                         | 23:16 | 15:8           | 7:0 |
| 0...3   | NC-SI Header                  |       |                |     |
| 4...7   |                               |       |                |     |
| 8...11  |                               |       |                |     |
| 12...15 |                               |       |                |     |
| 16...19 | Response Code                 |       | Reason Code    |     |
| 20...23 | Manufacturer ID (Intel 0x157) |       |                |     |
| 24...27 | 0x4C                          | 0x2   | Measured Value |     |
| 28...31 | Active Actions                |       |                |     |
| 32...33 | Threshold cross events        |       |                |     |

Where “Threshold cross events” is a bitmap that describes which events were crossed since the last read of the status or since the activation of the thermal sensor (the latest of the two).

Bit ‘n’ in the bitmap represent threshold index ‘n’ as configured in the Set Thermal Sensor Configuration command ([Section 11.6.3.19.1](#)).

Active actions can be set for the following actions (if supported by the device):

- Measure only
- Notify BMC
- Power off PHY

- Set speed to 10 Mb/s Max
- Set speed to 100 Mb/s Max
- Set speed to 1 Gb/s Max
- Set speed to 10 Gb/s Max
- Indicate on SDP (set)
- Indicate on SDP (clear)
- HW autonomous algorithm.

### 11.6.3.19 Set Thermal Sensor Commands (Intel Command 0x4D)

#### 11.6.3.19.1 Set Thermal Sensor Configuration Command (Intel Command 0x4D, Index 0x1)

This command sets the thermal sensor configuration for threshold “Index”

The threshold and the Hysteresis are measured in “unit types”.

**Note:** If the Max hysteresis reported in the Thermal Sensor capabilities is zero, the Hysteresis value is ignored.

The *Actions Going High* field describes the actions to activate upon crossing of the threshold for “Going High” thresholds or when crossing the hysteresis for “Going Low” thresholds according to [Table 11-39](#).

The *Actions Going Low* field describes the actions to activate upon crossing of the threshold for “Going Low” thresholds or when crossing the hysteresis for “Going High” thresholds according to [Table 11-39](#).

Direction is encoded as follows:

- 0 = High Going
- 1 = Low Going

| Bytes   | Bits                          |       |                            |           |
|---------|-------------------------------|-------|----------------------------|-----------|
|         | 31:24                         | 23:16 | 15:8                       | 7:0       |
| 0...3   | NC-SI Header                  |       |                            |           |
| 4...7   |                               |       |                            |           |
| 8...11  |                               |       |                            |           |
| 12...15 |                               |       |                            |           |
| 16...19 | Manufacturer ID (Intel 0x157) |       |                            |           |
| 20...23 | 0x4D                          | 0x01  | Index                      | Direction |
| 24...27 | Threshold                     |       | Actions “Going High” (MSB) |           |
| 28...31 | Actions “Going High” (LSB)    |       | Actions “Going Low” (MSB)  |           |
| 32...34 | Actions “Going Low” (LSB)     |       | Hysteresis                 |           |

**Note:** If Index and Direction points to a non valid threshold as described in the Get Thermal Sensor Capabilities Response, the command fails with an Invalid Parameter reason.

**Note:** If the requested action is not supported as defined in Get Thermal Sensor Capabilities Command ([Section 11.6.3.18.2](#)), the command fails with an Invalid Parameter reason.

**Note:** Actions set can not be contradictory - so for a given set of actions, the following combinations are invalid, and result in a command fails with an Invalid Parameter reason:

- Indicate on SDP (set) and Indicate on SDP (clear) both set,
- Power Down PHY and Power up PHY both set.
- Increase and Reduce Speed both set.
- Both a Speed update and a PHY power down action are requested.
- Do Nothing and another option are requested.
- HW independent algorithm and another option are requested.

#### 11.6.3.19.1.1 Set Thermal Sensor Configuration Response (Intel Command 0x4D, Index 0x1)

|         | Bits                          |       |             |     |
|---------|-------------------------------|-------|-------------|-----|
| Bytes   | 31:24                         | 23:16 | 15:8        | 7:0 |
| 0...3   | NC-SI Header                  |       |             |     |
| 4...7   |                               |       |             |     |
| 8...11  |                               |       |             |     |
| 12...15 |                               |       |             |     |
| 16...19 | Response Code                 |       | Reason Code |     |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |     |
| 24...25 | 0x4D                          | 0x1   |             |     |

#### 11.6.3.19.2 Set Thermal Sensor Action Command (Intel Command 0x4D, Index 0x2)

This command executes actions immediately.

The *Actions* field describes the actions to activate according to [Table 11-39](#).

| Bytes   | Bits                          |       |               |     |
|---------|-------------------------------|-------|---------------|-----|
|         | 31:24                         | 23:16 | 15:8          | 7:0 |
| 0...3   | NC-SI Header                  |       |               |     |
| 4...7   |                               |       |               |     |
| 8...11  |                               |       |               |     |
| 12...15 |                               |       |               |     |
| 16...19 | Manufacturer ID (Intel 0x157) |       |               |     |
| 20...23 | 0x4D                          | 0x02  | Actions (MSB) |     |
| 24...25 | Actions (LSB)                 |       |               |     |

**Note:** If one of the requested actions is not supported as defined in Get Thermal Sensor Capabilities Command ([Section 11.6.3.18.2](#)), the command fails with an Invalid Parameter reason.

**Note:** Actions set can not be contradictory - so the following combinations are invalid and result in a command fails with an Invalid Parameter reason:

- Indicate on SDP (set) and Indicate on SDP (clear) both set,
- Power Down PHY and Power up PHY both set.
- Restore and one of the Reduce Speed both set.
- Both a Speed update and a PHY power down action are requested.
- Do Nothing and another option are requested.
- HW independent algorithm and another option are requested.

#### 11.6.3.19.2.1 Set Thermal Sensor Action Response (Intel Command 0x4D, Index 0x2)

|         | Bits                          |       |             |     |
|---------|-------------------------------|-------|-------------|-----|
| Bytes   | 31:24                         | 23:16 | 15:8        | 7:0 |
| 0...3   | NC-SI Header                  |       |             |     |
| 4...7   |                               |       |             |     |
| 8...11  |                               |       |             |     |
| 12...15 |                               |       |             |     |
| 16...19 | Response Code                 |       | Reason Code |     |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |     |
| 24...25 | 0x4D                          | 0x2   |             |     |

### 11.6.3.20 Intel OEM AENs

#### 11.6.3.20.1 Thermal Sensor AEN (Intel AEN 0x81)

The following is the AEN that may be sent by the NC following a Thermal Sensor event.

This AEN must be enabled using the NC-SI “AEN Enable” command, using bit 17 (0x20000) of the AEN Enable mask.

This AEN is sent on all the channels on which it is enabled.

### 11.6.4 Asynchronous Event Notifications

|         | Bits                       |                                              |                |      |
|---------|----------------------------|----------------------------------------------|----------------|------|
| Bytes   | 31:24                      | 23:16                                        | 15:8           | 7:0  |
| 0...3   | NC-SI AEN Header           |                                              |                |      |
| 4...7   |                            |                                              |                |      |
| 8...11  |                            |                                              |                |      |
| 12...15 |                            |                                              |                |      |
| 20...23 | Reserved                   |                                              |                | 0x81 |
| 24...27 | Index of threshold crossed | Direction<br>0 = High Going<br>1 = Low Going | Measured Value |      |
| 28...31 | Active Actions             |                                              |                |      |

The asynchronous event notifications are unsolicited messages sent from the NC to the BMC to report status changes (such as link change, operating system state change, etc.).

Recommendations:

- The BMC firmware designer should use AENs. To do so, the designer must take into account the possibility that a NC-SI response frame (such as a frame with the NC-SI EtherType), arrives out-of-context (not immediately after a command, but rather after an out-of-context AEN).
- To enable AENs, the BMC should first query which AENs are supported, using the Get Capabilities command, then enable desired AEN(s) using the Enable AEN command, and only then enable the channel using the Enable Channel command.

### 11.6.5 Querying Active Parameters

The BMC can use the Get Parameters command to query the current status of the operational parameters.

## 11.6.6 Resets

In NC-SI there are two types of resets defined:

1. Synchronous entry into the initial state.
2. Asynchronous entry into the initial state.

Recommendations:

- It is very important that the BMC firmware designer keep in mind that following any type of reset, all configurations are considered as lost and thus the BMC must re-configure everything.
- As an asynchronous entry into the initial state might not be reported and/or explicitly noticed, the BMC should periodically poll the NC with NC-SI commands (such as Get Version ID, Get Parameters, etc.) to verify that the channel is not in the initial state. Should the NC channel respond to the command with a Clear Initial State Command Expected reason code, the BMC should consider the channel (and most probably the entire NC package) as if it underwent a (possibly unexpected) reset event. Thus, the BMC should re-configure the NC. See the NC-SI specification section on Detecting Pass-through Traffic Interruption.
- The Intel recommended polling interval is 2-3 seconds.

For exact details on the resets, refer to NC-SI specification.

## 11.6.7 Advanced Workflows

### 11.6.7.1 Multi-NC Arbitration

As described in [Section 11.6.1.2](#), in a multi-NC environment, there is a need to arbitrate the NC-SI lines.

[Figure 11-9](#) shows the system topology of such an environment.

**Figure 11-9. Multi-NC Environment**

See Figure 11-9. The NC-SI Rx lines are shared between the NCs. To enable sharing of the NC-SI Rx lines, NC-SI has defined an arbitration scheme.

The arbitration scheme mandates that only one NC package can use the NC-SI Rx lines at any given time. The NC package that is allowed to use these lines is defined as selected. All the other NC packages are de-selected.

NC-SI has defined two mechanisms for the arbitration scheme:

1. Package selection by the BMC. In this mechanism, the BMC is responsible for arbitrating between the packages by issuing NC-SI commands (Select/De-Select Package). The BMC is responsible for having only one package selected at any given time.
2. Hardware arbitration. In this mechanism, two additional pins on each NC package are used to synchronize the NC package. Each NC package has an ARB\_IN and ARB\_OUT line and these lines are used to transfer Tokens. A NC package that has a token is considered selected.

**Note:** Hardware arbitration is enabled by the NC-SI HW Arbitration Enable configuration bit in *NVM Control Word 1*.

For details, refer to the NC-SI specification.

### 11.6.7.2 Package Selection Sequence Example

Following is an example work flow for a BMC and occurs after the discovery, initialization, and configuration.

Assuming the BMC needs to share the NC-SI bus between packages, the BMC should:

1. Define a time-slot for each device.
2. Discover, initialize, and configure all the NC packages and channels.
3. Issue a De-Select Package command to all the channels.
4. Set active\_package to 0x0 (or the lowest existing package ID).
5. At the beginning of each time slot the BMC should:
  - a. Issue a De-Select Package to the active\_package. The BMC must then wait for a response and then an additional timeout for the package to become de-selected (200  $\mu$ s). See the NC-SI specification table 10 — parameter NC Deselect to Hi-Z Interval.
  - b. Find the next available package (typically active\_package = active\_package + 1).
  - c. Issue a Select Package command to active\_package.

### 11.6.7.3 Multiple Channels (Fail-Over)

To support a fail-over scenario, it is required from the BMC to operate two or more channels. These channels might or might not be in the same package.

The key element of a fault-tolerance fail-over scenario is having two (or more) channels identifying to the switch with the same MAC Address, but only one of them being active at any given time (such as switching the MAC Address between channels). To accomplish this, NC-SI provides the following commands:

1. Enable Network Tx command — This command enables shutting off the network transmit path of a specific channel. This enables the BMC to configure all the participating channels with the same MAC Address but only enable one of them.
2. Link Status Change AEN or Get Link Status command.

### 11.6.7.3.1 Fail-Over Algorithm Example

The following is a sample workflow for a fail-over scenario for the X550 Quad-port 10 GbE controller (one package and four channels):

1. BMC initializes and configures all channels after power-up. However, the BMC uses the same MAC Address for all of the channels.
2. The BMC queries the link status of all the participating channels. The BMC should continuously monitor the link status of these channels. This can be accomplished by listening to AENs (if used) and/or periodically polling using the Get Link Status command.
3. The BMC then only enables channel 0 for network transmission.
4. The BMC then issues a gratuitous ARP (or any other packet with its source MAC Address) to the network. This packet informs the switch that this specific MAC Address is registered to channel 0's specific LAN port.
5. The BMC begins normal workflow.
6. Should the BMC receive an indication (AEN or polling) that the link status for the active channel (channel 0) has changed, the BMC should:
  - a. Disable channel 0 for network transmission.
  - b. Check if a different channel is available (link is up).
  - c. If found:
    1. Enable network Tx for that specific channel.
    2. Issue a gratuitous ARP (or any other packet with its source MAC Address) to the network. This packet informs the switch that this specific MAC Address is registered to channel 0's specific LAN port.
    3. Resume normal workflow.
    4. If not found, report the error and continue polling until a valid channel is found.

The above algorithm can be generalized such that the start-up and normal workflow are the same. In addition, the BMC might need to use a specific channel (such as channel 0). In this case, the BMC should switch the network transmit to that specific channel as soon as that channel becomes valid (link is up).

#### Recommendations:

- Wait for a link-down-tolerance timeout before a channel is considered invalid. For example, a link re-negotiation might take a few seconds (normally 2 to 3 or might be up to 9). Thus, the link must be re-established after a short time.
- Typically, this timeout is recommended to be three seconds.
- Even when enabling and using AENs, periodically poll the link status, as dropped AENs might not be detected.

#### 11.6.7.4 Statistics

The BMC might use the statistics commands as defined in NC-SI. These counters are meant mostly for debug purposes and are not all supported.

The statistics are divided into three commands:

1. Controller statistics — These are statistics on the network interface (to the host operating system and the pass-through traffic). See the NC-SI specification for details.
2. NC-SI statistics — These are statistics on the NC-SI control frames (such as commands, responses, AENs, etc.). See the NC-SI specification for details.

NC-SI pass-through statistics — These are statistics on the NC-SI pass-through frames. See the NC-SI specification for details.

#### 11.6.8 External Link Control via NC-SI

The BMC can use the NC-SI Set Link command to control the external interface link settings. This command enables the BMC to set the auto-negotiation, link speed, duplex, and other parameters.

This command is only available when the host operating system is not present. Indicating the host operating system status can be obtained via the Get Link Status command and/or Host OS Status Change AEN command.

Recommendation:

- Unless explicitly needed, it is not recommended to use this feature. The NC-SI Set Link command does not expose all the possible link settings and/or features. This might cause issues under different scenarios. Even if you decided to use this feature, use it only if the link is down (trust the X550 until proven otherwise).
- It is recommended that the BMC first query the link status using the Get Link Status command. The BMC should then use this data as a basis and change only the needed parameters when issuing the Set Link command.

For details, refer to the NC-SI specification.

##### 11.6.8.1 Set Link While LAN PCIe Functionality is Disabled

In cases where the X550 is used solely for manageability and its LAN PCIe function is disabled, using the NC-SI Set Link command while advertising multiple speeds and enabling auto-negotiation results in the lowest possible speed chosen.

To enable link of higher a speed, the BMC should not advertise speeds that are below the desired link speed, as the lowest advertised link speed is chosen.

When the X550 is only used for manageability and the link speed advertisement is configured by the BMC, changes in the power state of the LAN device is not effected and the link speed is not re-negotiated by the LAN device.

### 11.6.8.2 Set Link Error Codes

The following rules are used to define the error code returned for Set Link command in case an invalid configuration is requested:

1. Host Driver Check: If host device driver is present, return a Command Specific Response (0x9) with a Set Link Host OS/Driver Conflict Reason (0x1).
2. Speed Present Check: If no speed is selected, return a General Reason Code for a failed command (0x1) with Parameter Is Invalid, Unsupported, or Out-of-Range Reason (0x2).
3. Parameter Validity:
  - a. Auto-Negotiation Parameter Validation: If auto-negotiation is requested and none of the selected parameters are valid for the device, return a General Reason Code for a failed command (0x1) with a Parameter Is Invalid, Unsupported, or Out-of-Range Reason (0x2).

**Note:** This means that, for example, a command requesting 10 GbE on a 1 GbE device succeeds provided that the command requests at least one other supported speed.

The same goes for an unsupported duplex setting (a device with no HD support accepts a command with both FD and HD set), and also for HD being requested with speeds of 1 GbE and higher as long as a speed below 1 GbE is also requested (and is supported in HD). The device simply ignores the unsupported parameters.

- b. Force Mode Parameter Validation:
    - If more than one link speed is being forced, return a General Reason Code for a failed command (0x1) and a Command Specific Reason with a Set Link Speed Conflict Error (0x0905).
    - If more than one duplex setting is being forced, return a General Reason Code for a failed command (0x1) with Parameter Is Invalid, Unsupported, or Out-of-Range Reason (0x2).
    - If 1 GbE and above is requested with HD, return a General Reason Code for a failed command (0x1) and a Command Specific Reason with Set Link Parameter Conflict Reason (0x0903).
4. Media Type Compatibility Check: If current media type is not compatible for the requested link parameters, return a General Reason Code for a failed command (0x1) and a Command Specific Reason with Set Link Media Conflict Error (0x0902).
5. Power State Compatibility Check: If current power state does not allow for the requested link parameters, return a General Reason Code for a failed command (0x1) and a Command Specific Reason with Set Link Power Mode Conflict Reason (0x0904).
6. If for some reason the hardware cannot perform the flow required for the command, return a General Reason Code for a failed command (0x1) and a Command Specific Response (0x9) with Link Command Failed-Hardware Access Error (0x6).

### 11.6.8.3 Support for 2.5 and 5 Gb/s Speeds

As the Set Link and Get Link commands do not support the proprietary 2.5 and 5 Gb/s speeds, the following behavior is defined:

- A Get Link response returns a speed indication of 1 Gb/s if a speed of 2.5 or 5 Gb/s was negotiated.
- There is no way to request a specific speed of 2.5 or 5 Gb/s in a Set Link command.
- If both 1 Gb/s and 10 Gb/s are requested in the auto-negotiation, 2.5 and 5 Gb/s are also enabled.

## 11.7 MCTP

### 11.7.1 MCTP Overview

The Management Component Transport Protocol (MCTP) defines a communication model intended to facilitate communication between:

- Management controllers and other management controllers.
- Management controllers and management devices.

The communication model includes a message format, transport description, message exchange patterns, and configuration and initialization messages.

The basic MCTP specification is described in DMTF's DSP0236 document.

MCTP is designed so that it can potentially be used on many bus types. The protocol is intended to be used for intercommunication between elements of platform management subsystems used in computer systems, and is suitable for use in mobile, desktop, workstation, and server platforms.

Currently, specifications exist for MCTP over PCI Express (DMTF's DSP0238) and over SMBus (DMTF's DSP0237). A specification for MCTP over USB is also planned. Management controllers such as a baseboard management controller (BMC) can use this protocol for communication between one another, as well as for accessing management devices within the platform.

#### 11.7.1.1 NC-SI Over MCTP

MCTP is a transport layer protocol that does not include the functionality required to control the pass-through traffic required for BMC connection to the network. This functionality is provided by encapsulating NC-SI traffic as defined in DMTF's DSP0222 document.

The details of NC-SI over MCTP protocol are defined in the NC-SI Over MCTP Specification.

The NC-SI over MCTP specification defines two types of MCTP message types: NC-SI (0x2) and Ethernet (0x3). The X550 supports both messages. When used only for control, only the NC-SI (0x2) message type is supported.

In addition to the above message types supported by the X550, the PCIe based VDM message type is also supported over PCIe to support ACL commands.

Details of the NC-SI over MCTP can be found in [Section 11.7.5](#).

#### 11.7.1.2 MCTP Usage Model

The X550 supports NC-SI over MCTP protocol over the PCI Express and SMBus buses. The X550 can connect through MCTP to a BMC or the ME engine in the chipset as described in [Figure 11-10](#).

**Figure 11-10. MCTP Connections of the X550**

## 11.7.2 NC-SI to MCTP Mapping

The two network ports of the X550 (mapped to two NC-SI channels) are mapped to a single MCTP endpoint on SMBus and to another endpoint over PCIe.

The PCIe endpoint is mapped to a PCIe requester ID according to the following flow:

1. If the *Bus Master Enable* bit of at least one of the functions is set, the endpoint is mapped to the first available function.
2. If the *Bus Master Enable* bits of all functions are cleared, the MCTP endpoint on PCIe is not exposed and the MCTP traffic is routed through the SMBus endpoint.

The slave address used for the SMBus endpoint is the slave address of the first port.

Section 11.7.2.1 describes the transition between the two buses.

Both endpoints (SMBus and PCIe) may be active concurrently. However, pass-through traffic may be transferred only through one of them. If the PCIe endpoint is active, it is used for pass-through traffic. Otherwise, the SMBus endpoint is used. The *Set EID* command can be used to force the transition for the PCIe endpoint to the SMBus endpoint if the bus owner determines the PCIe channel is not functional.

For each channel (SMBus or PCIe), the X550 should expect MCTP commands from two sources: the bus owner and the BMC. In addition, it should expect pass-through traffic through one interface only. Thus, it should be able to process up to five interleaved commands/data:

- An MCTP control/OEM command from the PCIe bus owner (single packet message).
- An MCTP control/OEM command from the SMBus bus owner (single packet message).

- An MCTP control/OEM command from the BMC over SMBus (single packet message).
- An MCTP control/OEM command from the BMC over PCIe (single packet message).
- An NC-SI command or Ethernet packet from the BMC over the active channel.

A single source should not interleave packets it sends.

The topology used for MCTP connection is described in [Figure 11-11](#).

**Figure 11-11. MCTP Endpoints Topology**

### 11.7.2.1 Detection of BMC EID and Physical Address

To allow transactions between the BMC and the NIC, the bus physical address (SMBus or PCIe) and the EID of the partner needs to be discovered. The NICs do not try to discover the BMC, and assume the BMC initiates the connection. If the NIC is in NC-SI initial state, the EID and the physical address of the BMC are extracted from the *Clear Initial State* command parameters or any other NC-SI command received later with a channel ID of the X550. Subsequent pass-through traffic is received from or sent to this address only.

If the EID or the physical address of the NIC changes, it indicates the changes to bus owner so that the routing tables can be updated. There is no attempt to directly send an indication to the BMC about the change.

### 11.7.2.2 Bus Transition

This section defines the transition flow between PCIe and SMBus as the bus on which MCTP flows. Figure 11-12 describes the flow to transition between PCIe and SMBus. The following parameters are used to define the flow:

- NIC EID on PCIe
- NIC EID on SMBus
- NIC PCIe Target ID
- Bus Owner EID on PCIe
- Bus Owner EID on SMBus
- Bus Owner PCIe Target ID
- Bus Owner SMBus address
- BMC EID on PCIe
- BMC EID on SMBus
- BMC PCIe Target ID
- BMC SMBus address
- NIC SMBus address

All these variables are initialized to zero at power on apart from the SMBus address of the endpoint (NIC) which may be initialized from NVM value.

Figure 11-12. MCTP Bus Transition State Machine

### 11.7.2.2.1 Initial Assignment Flow

1. At power on, the NIC or BMC MCTP channel is connected to the SMBus, is not assigned an EID, and is in “Undiscovered” state.
2. The Bus Owner may preform an SMBus ARP cycle to assign an SMBus address to the NIC or to the BMC. Otherwise, a fixed address may be used. It is assumed that the SMBus address does not change after initialization time.
3. The Bus Owner performs an EID assignment using a *Set Endpoint ID* MCTP command. The NIC or the BMC captures the SMBus address of the Bus Owner from the *SMBus Source Slave address* field, the Bus Owner EID from the *Source Endpoint ID* field, and the NIC/BMC EID from the *Destination Endpoint ID* field in the MCTP header as described in Section 10.3 of DSP0236. The NIC/BMC is now in “discovered” state.
4. The BMC may detect the NIC EID using one of the two following modes:
  - Static configuration of the NIC SMBus address in the BMC database and *Get Routing Table Entries* command to find the EID matching the SMBus address.
  - Get all endpoints through a *Get Routing Table Entries* command and find endpoints supporting NC-SI using the *Get Message Type Support* command for each endpoint.
5. Once the NIC is found, the BMC may send a *Clear Initial State* command to the NIC to start the NC-SI configuration. The NIC captures the BMC SMBus address and BMC EID from any NC-SI command received.
6. After the NC-SI channels are enabled, traffic may be sent using the BMC and NIC addresses previously discovered.
7. The BMC may send a *Get UUID* command to get a unique identifier of the NIC that may be used later for re-connection upon topology changes.
8. If a firmware reset occurs, a *Discovery Notify MCTP* message should be sent by the device to restart the flow.

### 11.7.2.2.2 SMBus to PCIe Transition

1. If the NIC or the BMC detects that the PCIe bus is available by detecting a function that moved to D0 state, it may request a transition using a *Discovery Notify* MCTP command on the PCIe bus. This command should be sent with a “Route to Root-complex” addressing as described in DSP0238 Section 6.8. The source EID should be the EID previously assigned on the SMBus.
2. The bus owner should send an *Endpoint Discovery* command using Broadcast from RC routing to allow the NIC to register the Bus Owner EID allowed to set EIDs.
3. Upon reception of the *Discovery Notify* MCTP command on the PCIe bus, the Bus Owner sends a *Set Endpoint ID* MCTP command on the PCIe bus, and updates the routing table. The Bus Owner may choose to wait for the *Discovery Notify* MCTP command of both the BMC and the NIC to do the transition. The Bus Owner should try to keep the EID previously assigned on the SMBus as the EID on PCIe bus.
4. Upon reception of the *Set Endpoint ID* MCTP command, the NIC waits for an NC-SI command from the BMC indicating it is ready to transition the connection to PCIe. Upon reception of such a command, the NIC transitions its pass-through traffic to the PCIe bus using the newly-received addresses.

5. The BMC on its side needs to discover the PCIe address of the NIC. This can be done using the *Resolve Endpoint ID* command if only the physical address changed, or using the *Resolve Endpoint UUID* command also if both EID and physical address changed. It can then send an NC-SI command to the NIC to initiate the transition. The BMC should not send any pass-through packets from the moment it sent the first NC-SI command on the PCIe and the moment a response is received for this command.
6. The transition of NC-SI traffic (pass-through or commands/responses) from SMBus to PCIe should be done on a packet boundary and should not interrupt a packet fragmentation or reassembly.

### 11.7.2.2.3 PCIe Target ID Change

The target ID of one of the endpoints may change, either due to a new enumeration of the PCIe bus or due to the disabling of one of the functions in the device (move to a non D0 state). In this case the following flow should be used:

1. The endpoint should send a *Discovery Notify* MCTP command on the PCIe bus using the new Requester ID.
2. Upon reception of the *Discovery Notify* MCTP command with the new Requester ID, the Bus Owner sends a *Set Endpoint ID* MCTP command on the PCIe bus, and updates the routing table. The Bus Owner should try to keep the EID previously assigned on the SMBus as the EID on the previous Requester ID.
3. The Bus Owner sends a *Routing Information Update* command to all supporting endpoints that may then update the parameters of their counterpart they use.
4. If a firmware reset occurs, the same flow is used to re-establish a connection.

### 11.7.2.2.4 PCIe to SMBus Transition

1. If the NIC or the BMC detects that the PCIe bus is not available by detecting a transition of all functions to a non D0 state, it stops using the PCIe for pass-through traffic or NC-SI traffic.
2. The BMC, upon detection of the unavailability of the PCIe bus, transitions the NC-SI channel to the MCTP over SMBus as described above.

**Note:** The transition of NC-SI traffic (pass-through or commands/responses) from PCIe to SMBus may done at any stage and may interrupt a packet fragmentation or reassembly, as it is assumed that such a transition occurs only when the PCIe bus is not available anymore.

## 11.7.3 MCTP Over PCIe

### 11.7.3.1 Message Format

The message format used for NC-SI over MCTP over PCIe is as follows:

| +0                                                                |                     |   |                               |   |   |   |   | +1                              |           |   |   |   |                                       |   |                           | +2                  |                         |                    |                          |          |                                             |                        |             | +3   |   |        |     |   |   |   |   |
|-------------------------------------------------------------------|---------------------|---|-------------------------------|---|---|---|---|---------------------------------|-----------|---|---|---|---------------------------------------|---|---------------------------|---------------------|-------------------------|--------------------|--------------------------|----------|---------------------------------------------|------------------------|-------------|------|---|--------|-----|---|---|---|---|
| 7                                                                 | 6                   | 5 | 4                             | 3 | 2 | 1 | 0 | 7                               | 6         | 5 | 4 | 3 | 2                                     | 1 | 0                         | 7                   | 6                       | 5                  | 4                        | 3        | 2                                           | 1                      | 0           | 7    | 6 | 5      | 4   | 3 | 2 | 1 | 0 |
| FMT<br>011                                                        |                     |   | Type<br>10r2r1r0 <sup>1</sup> |   |   |   |   | R                               | TC<br>000 |   |   | R | A<br>t<br>t <sub>r</sub> <sup>2</sup> | R | T<br>H <sub>2</sub>       | T<br>D <sub>2</sub> | E<br>P <sub>2</sub>     | Attr<br>[1:0]<br>2 |                          | AT<br>00 |                                             | Length<br>00_000x_xxxx |             |      |   |        |     |   |   |   |   |
| PCI Requester ID                                                  |                     |   |                               |   |   |   |   |                                 |           |   |   |   |                                       |   | PCI Tag Field             |                     |                         |                    |                          |          | Message Code<br>Vendor Defined = 0111_1111b |                        |             |      |   |        |     |   |   |   |   |
|                                                                   |                     |   |                               |   |   |   |   |                                 |           |   |   |   |                                       |   | R                         |                     | Pad<br>Len <sup>3</sup> |                    | MCTP VDM<br>code - 0000b |          |                                             |                        |             |      |   |        |     |   |   |   |   |
| PCI Target ID (For Route by ID messages,<br>otherwise = Reserved) |                     |   |                               |   |   |   |   |                                 |           |   |   |   |                                       |   | Vendor ID = 0x1AB4 (DMTF) |                     |                         |                    |                          |          |                                             |                        |             |      |   |        |     |   |   |   |   |
| MCTP<br>Reserved                                                  |                     |   | Header<br>version = 1         |   |   |   |   | Destination endpoint ID         |           |   |   |   |                                       |   |                           | Source endpoint ID  |                         |                    |                          |          |                                             | S<br>O<br>M            | E<br>O<br>M | SEQ# |   | T<br>O | Tag |   |   |   |   |

### 11.7.3.2 PCIe Discovery Process

The X550 follows the discovery process described in Section 5.9 of the *MCTP PCIe VDM Transport Binding Specification* (DSP0238).

Upon reception of an Endpoint Discovery message (while in undiscovered stage), the X550 exposes the endpoint on the selected function as described above.

If the *Bus Master Enable* bit of the selected function is cleared after the endpoint was discovered, or if the bus number of the X550 changes due to a re-enumeration of the bus, the X550 sends a Discovery Notify message to indicate to the BMC that it should do a re-enumeration of the device to discover the new endpoint.

### 11.7.3.3 MCTP Over PCIe Special Features

The X550 supports the following optional features of MCTP when running over PCIe:

- Rate Limiting
- ACLs

#### 11.7.3.3.1 MCTP Uplink Rate Limiting

As the PCIe link can carry a traffic bandwidth much higher than what the BMC can sustain, to avoid drop of packets, the X550 allows rate limiting of the MCTP pass-through traffic. The X550 supports rate limiting between 1 Mb/s and 1 Gb/s. The following parameters defines the behavior of the rate limiter:

- Max rate limit (fixed from NVM via the *MCTP Rate* in the *MCTP Rate Limiter Config 1* word).
- The max burst size (fixed from NVM via the *MCTP Max Credits* field in the in the *MCTP Rate Limiter Config 2* word). To limit the max burst to one VDM, set this parameter to 5.
- Decision point (fixed from NVM via the *Decision Point Field* in the in the *MCTP Rate Limiter Config 2* word).

#### 11.7.3.3.2 Service Provider MCTP Endpoint ACLs

The X550 supports a set of ACLs that allows reception of sensitive commands only from specific bus number (in the requester ID). The device and function part of the Requester ID are ignored for this purpose.

If ACLs are enabled (using bit 5 in *NC-SI over MCTP Configuration* NVM word - [Section 6.5.4.17](#)) the following flow is used decide which packets are accepted.

Commands can be divided to 3 types:

- ACL programming commands: Such commands can be received only from the address that sent the *Prepare For Endpoint Discovery* command via broadcast routing.
- Sensitive commands including all the NC-SI commands and pass-through traffic. These commands can be received only from requesters whose bus number is set in the ACL list. If an MCTP packet is dropped, the SPMEACLD counter is increased. This counter can be read by the MCTP bus owner using the *Get ACL Violation Counters* command.
- Regular MCTP commands are received from any requester. However, the *Set EID* command is processed only if received from the address that sent the *Prepare For Endpoint Discovery* command via broadcast routing.

## 11.7.4 MCTP Over SMBus

The message format used for NC-SI over MCTP over SMBus is as follows:

| +0                              |                     |   |   |                    |   |   |   | +1                              |   |   |   |   |   |   |   | +2                 |   |   |   |   |   |   |                      | +3          |      |   |        |     |   |   |   |
|---------------------------------|---------------------|---|---|--------------------|---|---|---|---------------------------------|---|---|---|---|---|---|---|--------------------|---|---|---|---|---|---|----------------------|-------------|------|---|--------|-----|---|---|---|
| 7                               | 6                   | 5 | 4 | 3                  | 2 | 1 | 0 | 7                               | 6 | 5 | 4 | 3 | 2 | 1 | 0 | 7                  | 6 | 5 | 4 | 3 | 2 | 1 | 0                    | 7           | 6    | 5 | 4      | 3   | 2 | 1 | 0 |
| Destination Slave Address       |                     |   |   |                    |   |   | 0 | Command Code = MCTP = 0Fh       |   |   |   |   |   |   |   | Byte count         |   |   |   |   |   |   | Source Slave Address |             |      |   |        |     |   | 1 |   |
| MCTP Reserved                   |                     |   |   | Header version = 1 |   |   |   | Destination endpoint ID         |   |   |   |   |   |   |   | Source endpoint ID |   |   |   |   |   |   | S<br>O<br>M          | E<br>O<br>M | SEQ# |   | T<br>O | Tag |   |   |   |
| I<br>C<br>1                     | Message Type = 0x02 |   |   |                    |   |   |   | NC-SI Command/Pass-Through data |   |   |   |   |   |   |   |                    |   |   |   |   |   |   |                      |             |      |   |        |     |   |   |   |
| .....                           |                     |   |   |                    |   |   |   |                                 |   |   |   |   |   |   |   |                    |   |   |   |   |   |   |                      |             |      |   |        |     |   |   |   |
| NC-SI Command/Pass-Through data |                     |   |   |                    |   |   |   |                                 |   |   |   |   |   |   |   |                    |   |   |   |   |   |   |                      |             |      |   |        |     |   |   |   |
| PEC                             |                     |   |   |                    |   |   |   |                                 |   |   |   |   |   |   |   |                    |   |   |   |   |   |   |                      |             |      |   |        |     |   |   |   |

1. IC = 0

|                          |
|--------------------------|
| SMBus header/PEC         |
| MCTP header              |
| NC-SI header and payload |

### 11.7.4.1 SMBus Discovery Process

The X550 follows the discovery process described in Section 6.5 of the *MCTP SMBus/I<sup>2</sup>C Transport Binding Specification* (DSP0237). It indicates support for ASF in the SMBus getUID command (see [Section 11.5.5.4](#)). It responds to any SMBus command using the MCTP command code - so that the bus owner knows that the X550 supports MCTP.

**Note:** MCTP commands over SMBus are received from any master address and are answered to the sender. There is no capturing of the bus owner address from any specific command.

### 11.7.4.2 MCTP over SMBus Special Features

The X550 supports the following optional features of MCTP when running over SMBus:

- Simplified MCTP mode
- Fairness arbitration

#### 11.7.4.2.1 Simplified MCTP Mode

For some point-to-point implementations of MCTP the assembly process is simplified. In this mode, the Destination EID, Source EID, Packet sequence number, Tag Owner (TO) bit, and Message tag are ignored and the assembly is based only on the *SOM* & *EOM* bits. This bit is set according to the *Simplified MCTP* bit in the *NC-SI over MCTP Configuration* word in the NVM.

This mode is relevant only for MCTP over SMBus traffic and when the *Redirection Sideband Interface* is set to 10b (MCTP over SMBus only - no pass-through).

#### 11.7.4.2.2 Fairness Arbitration

When sending MCTP messages over SMBus, the X550 should respect the fairness arbitration as defined in Section 5.13 of DSP0237 when sending MCTP messages.

### 11.7.5 NC-SI Over MCTP

X550 support for NC-SI over MCTP is similar to the support for NC-SI over RMII with the following exceptions:

- A set of new NC-SI OEM commands used to expose the NC-SI over MCTP capabilities.
- The format of the packets is modified to account for the new transport layer as described below.

#### 11.7.5.1 NC-SI Packets Format

NC-SI over MCTP defines two different message types for pass-through and for control packets.

Packets with a message type equal to the Control packets *Message Type* field (default = 0x02) in the NVM are NC-SI control packets (commands, responses, and AENs), while packets with a *Message Type* equal to the pass-through packets *Message Type* field (default = 0x03) in the NVM are NC-SI pass-through packets

### 11.7.5.1.1 Control Packets

The format used for Control packets (Commands, Responses, and AENs) is as follows:

| +0                   |                                                    |   |   |                    |   |   |   | +1                      |   |   |   |   |   |   |   | +2                      |   |   |   |   |   |   |   | +3          |             |      |   |                      |     |   |   |
|----------------------|----------------------------------------------------|---|---|--------------------|---|---|---|-------------------------|---|---|---|---|---|---|---|-------------------------|---|---|---|---|---|---|---|-------------|-------------|------|---|----------------------|-----|---|---|
| 7                    | 6                                                  | 5 | 4 | 3                  | 2 | 1 | 0 | 7                       | 6 | 5 | 4 | 3 | 2 | 1 | 0 | 7                       | 6 | 5 | 4 | 3 | 2 | 1 | 0 | 7           | 6           | 5    | 4 | 3                    | 2   | 1 | 0 |
| SMBus or PCIe header |                                                    |   |   |                    |   |   |   |                         |   |   |   |   |   |   |   |                         |   |   |   |   |   |   |   |             |             |      |   |                      |     |   |   |
| MCTP Reserved        |                                                    |   |   | Header version = 1 |   |   |   | Destination endpoint ID |   |   |   |   |   |   |   | Source endpoint ID      |   |   |   |   |   |   |   | S<br>O<br>M | E<br>O<br>M | SEQ# |   | T<br>O<br>=<br>1     | Tag |   |   |

| Command Data         |                                                    |   |   |                    |   |   |   |                         |   |   |   |   |   |   |   | Checksum                |   |   |   |   |   |   |   |             |             |      |   |                      |     |   |   |
| Checksum             |                                                    |   |   |                    |   |   |   |                         |   |   |   |   |   |   |   |                         |   |   |   |   |   |   |   |             |             |      |   |                      |     |   |   |

1. The channel ID is defined as described in [Section 11.2.2.2](#)

|                   |
|-------------------|
| SMBus/PCIe header |
| MCTP header       |
| NC-SI header      |
| NC-SI Data        |

Note that the MAC header and MAC FCS present when working over NC-SI are not part of the packet in MCTP mode.

### 11.7.5.1.2 Pass-Through Packets

The format used for pass-through packets is as follows. This format is the same for either packets received from the network or packets received from the host.

The CRC is never included in the packet. In receive, the CRC is checked and removed by the X550. In transmit, the CRC is added by the X550.

| +0                   |                                                  |   |   |                    |   |   |   | +1                      |   |   |   |   |   |   |   | +2                 |   |   |   |   |   |   |   | +3              |     |      |   |        |     |   |   |

### 11.7.6 MCTP Programming

The MCTP programming model is based on:

- A set of MCTP commands used for the discovery process and for the link management. The list of supported commands is described in [Section 11.7.6.1](#).
- A subset of the NC-SI commands used in the regular NC-SI interface, including all the OEM commands as described in [Section 11.6.2](#) (NC-SI programming I/F). The specific commands supported are listed in [Table 11-27](#) and [Table 11-30](#).

**Note:** For all MCTP commands (both native MCTP commands and NCSI over MCTP), the response uses the Msg tag received in the request with TO bit cleared.

### 11.7.6.1 MCTP Commands Support

Table 11-41 lists the MCTP commands supported by the X550.

**Table 11-41. MCTP Commands Support**

| Command Code | Command Name                       | General Description                                                                                                                                                                                  | X550 Support as Initiator | X550 Support as Responder |
|--------------|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|---------------------------|
| 0x00         | Reserved                           | Reserved.                                                                                                                                                                                            | –                         | –                         |
| 0x01         | Set Endpoint ID                    | Assigns an EID to the endpoint at the given physical address.                                                                                                                                        | N/A                       | Yes                       |
| 0x02         | Get Endpoint ID                    | Returns the EID presently assigned to an endpoint. Also returns information about what type the endpoint is and its level of use of static EIDs. See <a href="#">Section 11.7.6.1.1</a> for details. | No                        | Yes                       |
| 0x03         | Get Endpoint UUID                  | Retrieves a per-device unique UUID associated with the endpoint. See <a href="#">Section 11.7.6.1.2</a> for details.                                                                                 | No                        | Yes                       |
| 0x04         | Get MCTP Version Support           | Lists which versions of the MCTP control protocol are supported on an endpoint. See <a href="#">Section 11.7.6.1.3</a> for details.                                                                  | No                        | Yes                       |
| 0x05         | Get Message Type Support           | Lists the message types that an endpoint supports. See <a href="#">Section 11.7.6.1.3.1</a> for details.                                                                                             | No                        | Yes                       |
| 0x06         | Get Vendor Defined Message Support | Used to discover an MCTP endpoint's vendor specific MCTP extensions and capabilities. See <a href="#">Section 11.7.6.1.4</a> for details.                                                            | No                        | Yes <sup>1</sup>          |
| 0x07         | Resolve Endpoint ID                | Used to get the physical address associated with a given EID.                                                                                                                                        | No                        | N/A                       |
| 0x08         | Allocate Endpoint IDs              | Used by the bus owner to allocate a pool of EIDs to an MCTP bridge.                                                                                                                                  | N/A                       | N/A                       |
| 0x09         | Routing Information Update         | Used by the bus owner to extend or update the routing information that is maintained by an MCTP bridge.                                                                                              | N/A                       | N/A                       |
| 0x0A         | Get Routing Table Entries          | Used to request an MCTP bridge to return data corresponding to its present routing table entries.                                                                                                    | No                        | N/A                       |
| 0x0B         | Prepare for Endpoint Discovery     | Used to direct endpoints to clear their "discovered" flags to enable them to respond to the Endpoint Discovery command.                                                                              | N/A                       | Yes <sup>1</sup>          |
| 0x0C         | Endpoint Discovery                 | Used to discover MCTP-capable devices on a bus, provided that another discovery mechanism is not defined for the particular physical medium.                                                         | No                        | Yes <sup>1</sup>          |
| 0x0D         | Discovery Notify                   | Used to notify the bus owner that an MCTP device has become available on the bus.                                                                                                                    | Yes <sup>1</sup>          | N/A                       |
| 0x0E         | Get Network ID                     | Used to get the MCTP network ID                                                                                                                                                                      | No                        | No                        |
| 0x0F         | Query Hop                          | Used to discover what bridges, if any, are in the path to a given target endpoint and what transmission unit sizes the bridges pass for a given message type when routing to the target endpoint.    | No                        | No                        |

1. These commands are supported only for MCTP over PCIe.

### 11.7.6.1.1 Get Endpoint ID

The Get Endpoint ID response of the X550 is described in [Table 11-42](#).

**Table 11-42. Get Endpoint ID Response**

| Byte | Description     | Value                                                                                           |
|------|-----------------|-------------------------------------------------------------------------------------------------|
| 1    | Completion Code |                                                                                                 |
| 2    | Endpoint ID     | 0x00 = EID not yet assigned..<br>Otherwise = Returns EID assigned using Set Endpoint ID command |
| 3    | Endpoint Type   | 0x00 (Dynamic EID, Simple Endpoint).                                                            |
| 4    | Medium Specific | 0x00 = PCIe<br>0x01 = SMBus — Fairness arbitration protocol supported.                          |

### 11.7.6.1.2 Get Endpoint UUID

The UUID returned is calculated according to the following functions:

Time Low = Read from MCTP UUID - Time Low LSB/MSB NVM words of Sideband Configuration Structure.

Time mid = Read from Read from MCTP UUID - Time Mid NVM word of Sideband Configuration Structure

Time High and version = Read from MCTP UUID - Time High and version NVM word of Sideband Configuration Structure

Clock Sec and Reserved = Read from MCTP UUID - Clock Seq NVM word of Sideband Configuration Structure

Node = MAC Address as taken from the PCI\_SERL and PCI\_SERH registers.

### 11.7.6.1.3 Get MCTP Version Support

[Table 11-43](#) describes the returned value according to the requested message type. The list of supported message types is based on the protocols enabled in the NVM and should be the same as the list reported in the *Get Message Type Support* command in [Section 11.7.6.1.3.1](#).

**Table 11-43. Get MCTP Version Support Returned Value**

| Byte  | Description                | Message type       |                                 |                        |                    |                                |                                   |
|-------|----------------------------|--------------------|---------------------------------|------------------------|--------------------|--------------------------------|-----------------------------------|
|       |                            | 0xFF (Base)        | 0x00 (Control Protocol Message) | 0x02 (NC-SI Over MCTP) | 0x03 (Ethernet)    | 0x7E (PCIe-based VDM Messages) | All Other or Unsupported Messages |
| 1     | Completion Code            | 0x0                |                                 |                        |                    |                                | 0x80                              |
| 2     | Version Number entry count | 3                  | 3                               | 1                      | 1                  | 2                              | 0                                 |
| 6:3   | Version number entry       | 0xF1F0FF00 (1.0)   | 0xF1F0FF00 (1.0)                | 0xF1F0F000 (1.0)       | 0xF1F0F000 (1.0)   | 0xF1F0FF00 (1.0)               | 0                                 |
| 9:7   | Version number entry 2     | 0xF1F1F000 (1.1.0) | 0xF1F1F000 (1.1.0)              | 0xF1F1F000 (1.1.0)     | 0xF1F1F000 (1.1.0) | 0xF1F1F000 (1.1.0)             |                                   |
| 13:10 | Version number entry 3     | 0xF1F2F000 (1.2.0) | 0xF1F2F000 (1.2.0)              |                        |                    |                                |                                   |

### 11.7.6.1.3.1 Get Message Type Support Command

The Get Message Type Support response of the X550 is described in [Table 11-44](#).

**Table 11-44. Get Message Type Support Response**

| Byte | Description                  | Value                                                                                                                         |
|------|------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| 1    | Completion Code              | 0x00                                                                                                                          |
| 2    | MCTP Message Type Count      | 0x01/0x02/0x03 - The X550 supports up to three additional message types, depending on the mode of operation and the bus used. |
| 3:5  | List of Message Type numbers | 0x02 (NC-SI over MCTP)                                                                                                        |
|      |                              | 0x03 (Ethernet). If pass-through is supported.                                                                                |
|      |                              | 0x7E (PCIe based VDM messages). Over PCIe. Also over SMBus if OEM commands are supported.                                     |

### 11.7.6.1.4 Get Vendor Defined Message Support Command

This command is supported only for MCTP over PCIe.

The Get Vendor Defined Message Support response of the X550 is described in [Table 11-45](#) if the Vendor ID Set Selector equals 0x00.

**Table 11-45. Get Vendor Defined Message Support Response**

| Byte | Description            | Value                                         |
|------|------------------------|-----------------------------------------------|
| 1    | Completion Code        | 0x00                                          |
| 2    | Vendor ID Set Selector | 0xFF = no more capability sets.               |
| 2:4  | Vendor ID              | 0x008086 (PCI id indicator + Intel vendor ID) |
| 5:6  | Version                | 0x0100 (version 1.0)                          |

### 11.7.6.1.5 Set Endpoint ID Command

The X550 supports the Set EID and Force EID operations defined in the Set Endpoint ID command. When operating over PCIe, the Set Discovered Flag operation is also supported. As endpoints in the X550 can be set only through their own interface, Set EID and Force EID are equivalent. The Reset EID operation is not supported by the X550.

The Set Endpoint ID response of the X550 is described in [Table 11-46](#).

**Table 11-46. Set Endpoint ID Response**

| Byte | Description       | Value                                                                                                                                          |
|------|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| 1    | Completion Code   | 0x00                                                                                                                                           |
| 2    | Completion Status | [1:0] = 00b - Device does not use an EID pool.<br>[3:2] = 00b - Reserved.<br>[5:4] = 00b - EID assignment accepted.<br>[7:6] = 00b - Reserved. |
| 3    | EID Setting       | If the EID setting was accepted, this value matches the EID passed in the request. Otherwise, this value returns the present EID setting.      |
| 4    | EID Pool Size     | Always return a zero.                                                                                                                          |

## 11.8 Manageability Host Interface

This section details host interaction with the manageability portion of the X550. The information within this section is only available to the host driver, the BMC does not have access.

### 11.8.1 HOST CSR Interface (Function 1/0)

The software device driver of all functions communicates with the manageability block through CSR access. The manageability is mapped to address space 0x15800 to 0x15FFF on the slave bus of each function.

**Note:** Writing to address 0x15800 from any function is targeted to the same address in the RAM.

### 11.8.2 Host Slave Command Interface to Manageability

This interface is used by the software device driver for several of the commands and for delivering various types of data in both directions (Manageability-to-Host and Host-to-Manageability).

The address space is separated into two areas:

- Direct access to the internal data RAM: The internal shared (between firmware and software) RAM is mapped to address space 0x15800 to 0x15EFF. Writing/reading to this address space goes directly to the RAM.
- Control register is located at address 0x15F00.

#### 11.8.2.1 Host Slave Command Interface Low Level Flow

This interface is used for the external host software to access the manageability subsystem. Host software writes a command block or read data structure directly from the data RAM. Host software controls these transactions through a slave access to the *HICR* control register (see [Section 8.2.2.20.5](#)).

The following flow shows the process of initiating a command to the manageability block:

1. The software clears the *FWSTS.FWRI* flag (clear by write one) to clear any previous firmware reset indications.
2. The software device driver takes ownership of the Management Host interface using the flow described in [Section 4.7](#).
3. The software device driver reads the *HOST Interface Control* Register (See [Section 8.2.2.20.5](#)) and checks that the *Enable* (*HICR.EN*) bit is set.
4. The software device driver writes the relevant command block into the RAM area that is mapped to addresses 0x15800-0x15EFF.
5. The software device driver sets the *Command* (*HICR.C*) bit in the *HOST Interface Control* Register (See [Section 8.2.2.20.5](#)). Setting this bit causes an interrupt to the ARC.
6. The software checks the *FWSTS.FWRI* flag to make sure a firmware reset didn't occur during the command processing. If this bit is set, the command may have failed.
7. The software device driver polls the *HOST Interface Control* register for the *Command* (*HICR.C*) bit to be cleared by firmware. The command should complete within half a second.

8. When firmware finishes with the command, it clears the *Command* (HICR.C) bit (if firmware replies with data, it should clear the bit only after the data is placed in the shared RAM area where the software device driver can read it).

If the software device driver reads the *HOST Interface Control* register and the HICR.SV bit is set to 1b, there is a valid status of the last command in the shared RAM. If the HICR.SV bit is not set, the command has failed with no status in the RAM.

On completion of access to the shared RAM software device driver should release ownership of the shared RAM using the flow described in [Section 4.7](#).

## 11.8.2.2 Host Interface Structure

### 11.8.2.2.1 Host Interface Command Structure

Table 11-47 describes the structure used by the software device driver to send a command to firmware using the Host slave command interface (shared RAM mapped to addresses 0x15800-0x15EFF).

**Table 11-47. Host Driver Command Structure**

| Byte(s) | Description   | Bit(s) | Value             | Description                                                                            |
|---------|---------------|--------|-------------------|----------------------------------------------------------------------------------------|
| 0       | Command       | 7:0    | Command Dependent | Specifies which host command to process.                                               |
| 1       | Buffer Length | 7:0    | Command Length    | Command Data Buffer length: 0 to 252, not including 32 bits of header.                 |
| 2       | Reserved      | 7:0    |                   | Reserved.                                                                              |
| 3       | Checksum      | 7:0    | Defined Below     | Checksum signature. If the value is 0xFF, the checksum is not checked by the firmware. |
| 255:4   | Data Buffer   | 7:0    | Command Dependent | Command Specific Data<br>Minimum buffer size = 0<br>Maximum buffer size = 252          |

### 11.8.2.2.2 Host Interface Status Structure

Table 11-48 lists the structure used by firmware to return a status to the software device driver via the Host slave command interface. A status is returned after a command has been executed.

**Table 11-48. Status Structure Returned to Host Driver**

| Byte(s) | Description   | Bit(s) | Value                                | Description                                                                                                                                                                                                                                                                                                    |
|---------|---------------|--------|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0       | Command       | 7:0    | Command Dependent                    | Command ID.                                                                                                                                                                                                                                                                                                    |
| 1       | Buffer Length | 7:0    | Status Dependent                     | Status buffer length: 252:0                                                                                                                                                                                                                                                                                    |
| 2       | Return Status | 7:0    | Depends on Command Executing Results | 0x1 = Status OK<br>0x2 = Illegal command ID<br>0x3 = Unsupported command<br>0x4 = Illegal payload length<br>0x5 = Checksum failed<br>0x6 = Data Error<br>0x7 = Invalid parameter<br>0x8-0x7F = Reserved<br>0x80-0xFF = Command Specific Errors. May be used by individual commands for command specific errors |

**Table 11-48. Status Structure Returned to Host Driver (Continued)**

| Byte(s) | Description | Bit(s) | Value            | Description                                                                                                                                              |
|---------|-------------|--------|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3       | Checksum    | 7:0    | Defined Below    | Checksum signature.                                                                                                                                      |
| 255:4   | Data Buffer |        | Status Dependent | Status configuration parameters<br>Minimum Buffer Size = 0<br>Maximal Buffer Size = 252<br>If Return Status is not "Status OK" the Data Buffer is empty. |

### 11.8.2.2.3 Checksum Calculation Algorithm

The Host Command/Status structure is summed with this field cleared to 0b. The calculation is done using 8-bit unsigned math with no carry. The inverse of this sum is stored in this field (0b minus the result). Result: The current sum of this buffer (8-bit unsigned math) is 0b.

## 11.8.3 Host Interface Commands

### 11.8.3.1 Driver Info Host Command

This command is used to provide the driver information in NC-SI mode.

**Table 11-49. Driver Info Host Command**

| Byte(s)                    | Name            | Bit(s) | Value                      | Description                                                                                                                                                                                     |
|----------------------------|-----------------|--------|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                          | Command         | 7:0    | 0xDD                       | Driver info command.                                                                                                                                                                            |
| 1                          | Buffer Length   | 7:0    | 0x5 + driver string length | Port Number + 4 bytes of the Driver info + driver string length (total length can be up to 255 bytes).                                                                                          |
| 2                          | Reserved        | 7:0    | 0x0                        | Reserved.                                                                                                                                                                                       |
| 3                          | Checksum        | 7:0    |                            | Checksum signature of the Host command.                                                                                                                                                         |
| 4                          | Function Number | 7:0    | Function Number            | Indicates the function currently reporting its driver info.                                                                                                                                     |
| 8:5                        | Driver Version  | 7:0    | Driver Version             | Numerical for driver version - should be:<br>Byte 8 = Major<br>Byte 7 = Minor<br>Byte 6 = Build<br>Byte 5 = SubBuild<br><b>Note:</b> The old version is kept to support CEM version 1 commands. |
| 9:9 + driver string length | Driver String   |        | Driver String              | Driver string (not null terminated) as reported by driver.<br>For example, in Linux the DRV_VERSION #define, or in NDIS, the OID_GEN_VENDOR_DRIVER_VERSION. Can be up to 250 bytes.             |

Following is the status returned on this command:

**Table 11-50. Driver Info Host Status**

| Byte(s) | Name          | Bit(s) | Value | Description                       |
|---------|---------------|--------|-------|-----------------------------------|
| 0       | Command       | 7:0    | 0xDD  | Driver Info command.              |
| 1       | Buffer Length | 7:0    | 0x0   | No data in return status.         |
| 2       | Return Status | 7:0    | 0x1   | See <a href="#">Table 11-48</a> . |
| 3       | Checksum      | 7:0    |       | Checksum signature.               |

### 11.8.3.2 Disable RXEN Command

This command is used to enable the driver to request a safe disable of Receive Enable.

**Table 11-51. Disable RXEN Command**

| Byte(s) | Name          | Bit(s) | Value       | Description                                              |
|---------|---------------|--------|-------------|----------------------------------------------------------|
| 0       | Command       | 7:0    | 0xDE        | Driver info command.                                     |
| 1       | Buffer Length | 7:0    | 0x1         | 1 data byte attached to this command (the port number).  |
| 2       | Reserved      | 7:0    | 0x0         | Reserved.                                                |
| 3       | Checksum      | 7:0    |             | Checksum signature of the Host command.                  |
| 4       | Port Number   | 7:0    | Port Number | Indicates the port for which the operation is requested. |

Following is the status returned on this command:

**Table 11-52. OS2BMC Control Status**

| Byte(s) | Name          | Bit(s) | Value | Description                       |
|---------|---------------|--------|-------|-----------------------------------|
| 0       | Command       | 7:0    | 0xDE  | Driver Info command.              |
| 1       | Buffer Length | 7:0    | 0x0   | No data in return status.         |
| 2       | Return Status | 7:0    | 0x1   | See <a href="#">Table 11-48</a> . |
| 3       | Checksum      | 7:0    |       | Checksum signature.               |

The firmware should execute the following flow when receiving this command:

- Store OS2BMC enable bit.
- Clear OS2BMC enable bit.
- Clear RXEN
- Restore OS2BMC enable bit to original value.
- Return from command.

### 11.8.3.3 Flash I/F interface

These commands allow buffers of up to 1Kbyte of data. To do this, the *Buffer Length* field is expanded to 2 bytes.

**Note:** This *Buffer Length* field in the command is in big endian order. For example, byte 1 contains the MSB part of the buffer length and byte 2 contains the LSB part of the buffer length. The buffer length in the response is in the reverse order (byte 1 contains the LSB and byte 2 [7:5] contains the MS bits).

#### 11.8.3.3.1 Flash Read

This command is used to request a read from the flash. This command allows access to the region of the flash owned by the device (in case of non-shared SPI, it is the entire flash).

This command always returns the value from the flash, even if read within the Shadow RAM boundaries.

**Table 11-53. Flash Read Command**

| Byte(s) | Name           | Bit(s) | Value | Description                                |
|---------|----------------|--------|-------|--------------------------------------------|
| 0       | Command        | 7:0    | 0x30  | Flash Read.                                |
| 2:1     | Buffer Length  | 15:0   | 0x6   |                                            |
| 3       | Checksum       | 7:0    |       | Checksum signature.                        |
| 7:4     | Address        | 31:0   |       | Address to read from the flash.            |
| 9:8     | Length to Read | 15:0   |       | How many bytes to read. Can be up to 1024. |

**Table 11-54. Flash Read Response**

| Byte(s)            | Name                    | Bit(s) | Value | Description                         |
|--------------------|-------------------------|--------|-------|-------------------------------------|
| 0                  | Command                 | 7:0    | 0x30  | Flash Read.                         |
| 1                  | Buffer Length (LS Byte) | 7:0    |       | Buffer length[7:0].                 |
| 2                  | Buffer Length (MS Byte) | 7:5    |       | Buffer length[10:8].                |
| 2                  | Return Status           | 4:0    |       | See <a href="#">Table 11-48</a> .   |
| 3                  | Checksum                | 7:0    |       | Checksum signature.                 |
| 7:4                | Address                 | 31:0   |       | Address to read from the flash.     |
| 9:8                | Length Read             | 15:0   |       | How many bytes where actually read. |
| 11:10              | Reserved                |        |       | Reserved.                           |
| 12: Length Read+12 | Read Data               |        |       | The Requested Data read from flash. |

### 11.8.3.3.2 Shadow RAM Read

This command is used to request a read from the Shadow RAM. Requesting addresses above Shadow RAM boundaries causes an error.

**Table 11-55. Shadow RAM Read Command**

| Byte(s) | Name           | Bit(s) | Value | Description                                |
|---------|----------------|--------|-------|--------------------------------------------|
| 0       | Command        | 7:0    | 0x31  | Shadow RAM Read.                           |
| 2:1     | Buffer Length  | 15:0   | 0x6   |                                            |
| 3       | Checksum       | 7:0    |       | Checksum signature.                        |
| 7:4     | Address        | 31:0   |       | Address to read from the Shadow RAM.       |
| 9:8     | Length to Read | 15:0   |       | How many bytes to read. Can be up to 1024. |

**Table 11-56. Shadow RAM Read Response**

| Byte(s)            | Name                    | Bit(s) | Value | Description                              |
|--------------------|-------------------------|--------|-------|------------------------------------------|
| 0                  | Command                 | 7:0    | 0x31  | Shadow RAM Read.                         |
| 1                  | Buffer Length (LS Byte) | 7:0    |       | Buffer length[7:0].                      |
| 2                  | Buffer Length (MS bits) | 7:5    |       | Buffer Length[10:8].                     |
| 2                  | Return Status           | 4:0    |       | See <a href="#">Table 11-48</a> .        |
| 3                  | Checksum                | 7:0    |       | Checksum signature.                      |
| 7:4                | Address                 | 31:0   |       | Address to read from the Shadow RAM.     |
| 9:8                | Length Read             | 15:0   |       | How many bytes were actually read.       |
| 11:10              | Reserved                |        |       | Reserved.                                |
| 12: Length Read+12 | Read Data               |        |       | The Requested Data read from Shadow RAM. |

### 11.8.3.3.3 Flash Write

This command is used to update the flash sections out of the Shadow RAM. This command allows access to the writable region of the flash owned by the device that is not part of the Shadow RAM. If not all the area to erase is writable, the command returns an error.

**Table 11-57. Flash Write Command**

| Byte(s)                 | Name            | Bit(s) | Value                 | Description                                 |
|-------------------------|-----------------|--------|-----------------------|---------------------------------------------|
| 0                       | Command         | 7:0    | 0x32                  | Flash Write.                                |
| 2:1                     | Buffer Length   | 15:0   | 0x8 + Length to Write |                                             |
| 3                       | Checksum        | 7:0    |                       | Checksum signature.                         |
| 7:4                     | Address         | 31:0   |                       | Address to write to the Shadow RAM.         |
| 9:8                     | Length to Write | 15:0   |                       | How many bytes to write. Can be up to 1024. |
| 11:10                   | Reserved        |        |                       | Reserved.                                   |
| 12: Length to Write +12 | Write Data      |        |                       | The data to write to the flash.             |

**Table 11-58. Flash Write Response**

| Byte(s) | Name          | Bit(s) | Value | Description                           |
|---------|---------------|--------|-------|---------------------------------------|
| 0       | Command       | 7:0    | 0x32  | Flash Write.                          |
| 1       | Buffer Length | 7:0    | 0x6   |                                       |
| 2       | Return Status | 7:0    |       | See <a href="#">Table 11-48</a> .     |
| 3       | Checksum      | 7:0    |       | Checksum signature.                   |
| 7:4     | Address       | 31:0   |       | Address to write to the Shadow RAM.   |
| 9:8     | Data Written  | 15:0   |       | How many bytes were actually written. |

### 11.8.3.3.4 Shadow RAM Write

This command is used to update the Shadow RAM. It allows write to the writable parts of the Shadow RAM. If not all the area to write is writable, or not all the area is in the Shadow RAM range, the command returns an error.

**Table 11-59. Shadow RAM Write Command**

| Byte(s)                | Name            | Bit(s) | Value                 | Description                                 |
|------------------------|-----------------|--------|-----------------------|---------------------------------------------|
| 0                      | Command         | 7:0    | 0x33                  | Shadow RAM write.                           |
| 2:1                    | Buffer Length   | 15:0   | 0x8 + Length to Write |                                             |
| 3                      | Checksum        | 7:0    |                       | Checksum signature.                         |
| 7:4                    | Address         | 31:0   |                       | Address to write to the flash.              |
| 9:8                    | Length to Write | 15:0   |                       | How many bytes to write. Can be up to 1024. |
| 11:10                  | Reserved        |        |                       |                                             |
| 12: Length to Write+12 | Write Data      |        |                       | The data to write to the Shadow RAM         |

**Table 11-60. Shadow RAM Write Response**

| Byte(s) | Name          | Bit(s) | Value | Description                           |
|---------|---------------|--------|-------|---------------------------------------|
| 0       | Command       | 7:0    | 0x33  | Shadow RAM Write.                     |
| 1       | Buffer Length | 7:0    | 0x6   |                                       |
| 2       | Return Status | 7:0    |       | See <a href="#">Table 11-48</a> .     |
| 3       | Checksum      | 7:0    |       | Checksum signature.                   |
| 7:4     | Address       | 31:0   |       | Address to write to the Shadow RAM.   |
| 9:8     | Data Written  | 15:0   |       | How many bytes were actually written. |

### 11.8.3.3.5 Flash Module Update

This command is used to update a secured module. After a successful response to this command, for a firmware code update, an *Apply Update* command (Section 11.8.3.3.6) is sent to activate the new firmware.

**Table 11-61. Flash Module Update Command**

| Byte(s) | Name          | Bit(s) | Value | Description                                                                                     |
|---------|---------------|--------|-------|-------------------------------------------------------------------------------------------------|
| 0       | Command       | 7:0    | 0x34  | Flash Module Update.                                                                            |
| 2:1     | Buffer Length | 15:0   | 0x1   |                                                                                                 |
| 3       | Checksum      | 7:0    |       | Checksum signature.                                                                             |
| 4       | Module ID     | 7:0    |       | Which module to update:<br>Firmware code = 0x1<br>PHY Firmware Image = 0x5<br>Option ROM = 0xFE |

**Table 11-62. Flash Module Update Response**

| Byte(s) | Name          | Bit(s) | Value | Description                                                                                  |
|---------|---------------|--------|-------|----------------------------------------------------------------------------------------------|
| 0       | Command       | 7:0    | 0x34  | Flash Module Update.                                                                         |
| 1       | Buffer Length | 7:0    | 0x0   |                                                                                              |
| 2       | Return Status | 7:0    |       | See Table 11-48.<br>If the Authentication failed, an Authentication Error (0x80) is returned |
| 3       | Checksum      | 7:0    |       | Checksum signature.                                                                          |

### 11.8.3.3.6 Apply Update

This command is used to request the firmware to switch to the new uploaded code. This command involves a firmware reset, so no response should be expected after this command is given. The software device driver may read the *FWRESETCNT* register before and after the command is given to check if the reset took place.

**Note:** An Apply Update command sent not after a successful Flash Module Update Command is ignored.

If after 100 ms the *FWRESETCNT* register has not increase, the software should assume the command failed.

**Table 11-63. Apply Update Command**

| Byte(s) | Name          | Bit(s) | Value | Description         |
|---------|---------------|--------|-------|---------------------|
| 0       | Command       | 7:0    | 0x38  | Apply Update.       |
| 2:1     | Buffer Length | 15:0   | 0x0   |                     |
| 3       | Checksum      | 7:0    |       | Checksum signature. |

### 11.8.3.3.7 Flash Block Erase

This command is used to erase some of the flash sections. This command allows access to the writable region of the flash owned by the device that is not part of the Shadow RAM. If not all the area to erase is writable, the command returns an error.

**Table 11-64. Flash Block Erase Command**

| Byte(s) | Name                       | Bit(s) | Value | Description                                                                                         |
|---------|----------------------------|--------|-------|-----------------------------------------------------------------------------------------------------|
| 0       | Command                    | 7:0    | 0x35  | Flash Block Erase.                                                                                  |
| 2:1     | Buffer Length              | 15:0   | 0x5   |                                                                                                     |
| 3       | Checksum                   | 7:0    |       | Checksum signature.                                                                                 |
| 7:4     | Address                    | 31:0   |       | Address of block to erase – must be 4K bytes aligned.                                               |
| 8       | Number of sectors to erase | 7:0    |       | How many 4KB sectors to erase. To avoid a too long command, this number should be no larger than 3. |

**Table 11-65. Flash Block Erase Response**

| Byte(s) | Name          | Bit(s) | Value | Description                           |
|---------|---------------|--------|-------|---------------------------------------|
| 0       | Command       | 7:0    | 0x35  | Flash Block Erase.                    |
| 1       | Buffer Length | 7:0    | 0x5   |                                       |
| 2       | Return Status | 7:0    |       | See <a href="#">Table 11-48</a> .     |
| 3       | Checksum      | 7:0    |       | Checksum signature.                   |
| 7:4     | Address       | 31:0   |       | Address of block to erase.            |
| 8       | Erased Blocks | 7:0    |       | How many blocks were actually erased. |

### 11.8.3.3.8 Shadow RAM Dump

This command is used to trigger a Shadow RAM dump. It should be used after updating a module in Shadow RAM.

**Table 11-66. Shadow RAM Dump Command**

| Byte(s) | Name          | Bit(s) | Value | Description         |
|---------|---------------|--------|-------|---------------------|
| 0       | Command       | 7:0    | 0x36  | Shadow RAM dump.    |
| 2:1     | Buffer Length | 15:0   | 0x0   |                     |
| 3       | Checksum      | 7:0    |       | Checksum signature. |

**Table 11-67. Shadow RAM Dump Response**

| Byte(s) | Name          | Bit(s) | Value | Description                       |
|---------|---------------|--------|-------|-----------------------------------|
| 0       | Command       | 7:0    | 0x36  | Shadow RAM dump.                  |
| 1       | Buffer Length | 7:0    | 0x0   |                                   |
| 2       | Return Status | 7:0    |       | See <a href="#">Table 11-48</a> . |
| 3       | Checksum      | 7:0    |       | Checksum signature.               |

### 11.8.3.3.9 Flash Info

This command is used to provide information about the Flash.

**Note:** If the connected Flash does not support SFDP, the JEDEC ID information – *Valid* field is not set.

**Table 11-68. Flash Info Command**

| Byte(s) | Name          | Bit(s) | Value | Description         |
|---------|---------------|--------|-------|---------------------|
| 0       | Command       | 7:0    | 0x37  | Flash Info.         |
| 2:1     | Buffer Length | 15:0   | 0x0   |                     |
| 3       | Checksum      | 7:0    |       | Checksum signature. |

**Table 11-69. Flash Info Response**

| Byte(s) | Name                                                  | Bit(s) | Value | Description                                                                                                                                                                                                           |
|---------|-------------------------------------------------------|--------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0       | Command                                               | 7:0    | 0x37  | Flash Info.                                                                                                                                                                                                           |
| 1       | Buffer Length                                         | 7:0    | 0x8   |                                                                                                                                                                                                                       |
| 2       | Return Status                                         | 7:0    |       | See <a href="#">Table 11-48</a> .                                                                                                                                                                                     |
| 3       | Checksum                                              | 7:0    |       | Checksum signature.                                                                                                                                                                                                   |
| 7:4     | Flash Size                                            | 31:0   |       | Size of flash available to this device in bytes. In case on non-shared SPI, it is the size of the flash.<br>In case of SFDP flash, the size from the SFDP data is reported, otherwise the value from NVM is reported. |
| 8       | JEDEC ID information – Bank                           | 6:0    |       | Defines the bank number of the manufacturer ID (number of 0x7F read).                                                                                                                                                 |
|         | JEDEC ID information – Valid                          | 7      |       | The JEDEC ID information is valid (is not set in shared SPI modes).                                                                                                                                                   |
| 9       | JEDEC ID information – Manufacturer ID                | 7:0    |       | Returns the manufacturer ID read by RDID command.                                                                                                                                                                     |
| 10      | JEDEC ID information – Device ID 1 <sup>st</sup> byte | 7:0    |       | First byte of the device ID read by RDID command ( <i>Family</i> and <i>Density</i> fields).                                                                                                                          |
| 11      | JEDEC ID information – Device ID 2 <sup>nd</sup> byte | 7:0    |       | Second byte of the device ID read by RDID command (Sub version and Revision).                                                                                                                                         |

## 11.8.4 Software and Firmware Synchronization

Software and firmware synchronize accesses to shared resources in the X550 through a semaphore mechanism and a shared configuration register between the software device driver of the two ports and the firmware. This semaphore enables synchronized accesses to the following shared resources:

- NVM
- PHY 0 and PHY 1 registers
- MAC (LAN controller) shared registers. This semaphore protects the MAC registers described in [Section 8.2.2.16](#).
- I<sup>2</sup>C

The SW\_FW\_SYNC.REGSMP bit is used as a semaphore mechanism between software and firmware. Once software or firmware takes control over this semaphore flag, it can access the SW\_FW\_SYNC Register and claim ownership over specific resources. The SW\_FW\_SYNC includes pairs of bits (one owned by software and the other by firmware), where each pair of bits controls a different resource. A resource is owned by software or firmware when its respective bit is set. It is illegal to have both pair bits set at the same time. Described below are the required sequences for gaining and releasing control over shared resources.

### 11.8.4.1 Gaining Control of Shared Resource by Software

1. The software device driver checks that the software device driver of the other LAN function does not use the software/firmware semaphore.
  - The software device driver polls the SWSM.SMBI bit till it is read as 0b, or time expires (recommended expiration is ~10 ms + expiration time used for the SW\_FW\_SYNC.REGSMP).
  - If the SWSM.SMBI is found at 0b, the semaphore is taken. Note that following this read cycle the hardware auto sets the bit to 1b.
  - If time expired, it is assumed that the software device driver of the other function malfunctioned. The software proceeds to the next step.
2. The software device driver checks that the firmware does not use the software/firmware semaphore and then takes its control.
  - Software polls the SW\_FW\_SYNC.REGSMP bit till it is read as 0b, or time expires (recommended expiration is ~50 ms). If time has expired the software assumes that the firmware malfunctioned and proceeds to the next step, while ignoring the firmware bits in the SW\_FW\_SYNC register.
3. The software takes control of the requested resource(s).
  - The software device driver reads the firmware and software bit(s) of the requested resource(s) in the SW\_FW\_SYNC register. If the bit(s) is cleared, the resource(s) is accessible (i.e. no other entity owns the resource(s)). In this case the software device driver sets the software bit(s) of the requested resource(s) in the SW\_FW\_SYNC register. The software then clears the SW\_FW\_SYNC.REGSMP and SWSM.SMBI bits (releasing the software/firmware semaphore register), and can use the specific resource(s).
  - Otherwise (i.e. either firmware or software of the other LAN function owns the resource), the software clears the SW\_FW\_SYNC.REGSMP and SWSM.SMBI bits and then repeats the entire process after some delay (recommended 5-10 ms).
    - If the resources are not released by the software device driver of the other LAN function in a timely manner (recommended expiration time is ~1 sec), the software device driver can assume that the other software device driver malfunctioned. In that case the software device driver should clear all software flags that it does not own (including SW\_FW\_SYNC.REGSMP bit) and then repeat the entire process once again.
    - If the resource is not released by the firmware (recommended expiration time for firmware is ~50 ms) the software device driver can assume that the firmware malfunctioned. In that case the software device driver should set the software bit(s) of the requested resource(s), while ignoring the corresponding firmware bits in the SW\_FW\_SYNC register.

Note that the firmware initializes its semaphore flags as part of its init flow. The software semaphores are not reset.

#### 11.8.4.2 Releasing a Shared Resource by Software

1. The software device driver takes control over the software/firmware semaphore as described above for gaining shared resources.
2. The software device driver clears the bit(s) of the released resource(s) in the SW\_FW\_SYNC register.
3. The software device driver releases the software/firmware semaphore by clearing the SW\_FW\_SYNC.REGSMP and SWSM.SMBI bits
4. The software device driver should delay (recommended 5-10 ms) before trying to gain the semaphore immediately following its release.

#### 11.8.4.3 Gaining Control of Shared Resource by Firmware

1. The firmware takes control over the software/firmware semaphore (SW\_FW\_SYNC register)
  - The firmware polls the SW\_FW\_SYNC.REGSMP bit till it is read as 0b, or timeout expires (recommended expiration time is ~10 ms).
  - If timeout has expired the firmware clears the SW\_FW\_SYNC.REGSMP bit (it is assumed the software device driver is not functional).
2. The firmware takes ownership of the requested resources
  - The firmware reads the software bit(s) corresponding to the requested firmware resource(s) in the SW\_FW\_SYNC register.
  - If the software bit is cleared (i.e. the software device driver does not own the resource), the firmware sets the firmware bit(s) of the requested resource(s). The firmware then clears the SW\_FW\_SYNC.REGSMP bit (releasing the software/firmware semaphore) and can use the specific resource(s).
  - Otherwise (i.e. software owns the resource), the firmware clears the SW\_FW\_SYNC.REGSMP bit and then repeats the above process after some delay (recommended delay of 5-10 ms).
    - If the resources owned by software are not released in a timely manner (~1 sec), the firmware “forces” its ownership over the requested resources. The firmware clears the software flags of the requested resources in the SW\_FW\_SYNC register (assuming the software that set those flags is not functional).

#### 11.8.4.4 Releasing a Shared Resource by the Firmware

1. The firmware takes control over the software/firmware semaphore as described above for gaining shared resources.
2. The firmware clears the bit(s) of the selected resource(s) in the SW\_FW\_SYNC register.
3. The firmware releases the software/firmware semaphore by clearing the SW\_FW\_SYNC.REGSMP bit.
4. The firmware should delay before trying to gain the selected resource semaphore immediately following its release (recommended 5-10 ms).

## 11.9 Host Isolate Support

If a BMC decides that a malicious software prevents its usage of the LAN, it may decide to isolate the NIC from its driver. This is done using the TCO reset command ([Section 11.6.3.14](#)).

If TCO isolate is enabled in the NVM ([Section 6.5.2.2](#)), The TCO Isolate command disables PCIe write operations to the LAN port. As the driver needs to access the CSR space to provide descriptors to the NIC, this operation also stops the network traffic including OS-to-BMC and BMC-to-OS traffic as soon as the existing transmit and receive descriptor queues are exhausted.

**NOTE:**      *This page intentionally left blank.*

## 12.0 Electrical/Mechanical Specification

### 12.1 Introduction

This section describes the X550 DC and AC (timing) electrical characteristics and the X550 package specification. This includes absolute maximum rating, recommended operating conditions, power sequencing requirements, DC and AC timing specifications. The DC and AC characteristics include generic digital IO specification as well as other specifications of interfaces supported by the X550.

### 12.2 Operating Conditions

#### 12.2.1 Absolute Maximum Ratings

| Symbol        | Parameter                   | Min  | Max  | Units |
|---------------|-----------------------------|------|------|-------|
| $T_{case}$    | Case Temperature Under Bias | 0    | 107  | °C    |
| $T_{storage}$ | Storage Temperature Range   | -50  | 150  | °C    |
| VCC3P3        | 3.3 Voltage                 | -500 | 3630 | mV    |
| VCC2P1        | 2.1 Voltage                 | -500 | 2320 | mV    |
| VCC1P2        | 1.2 Voltage                 | -500 | 1320 | mV    |
| VCC0P83       | 0.83 Voltage                | -500 | 1190 | mV    |
| $V_{ESD}$     | ESD On All Pins Except Line |      | 2    | kV    |
| $V_{CD}$      | Cable Discharge On Line     |      | 3    | kV    |

**Note:** Stresses above those listed in the table can cause permanent device damage. These values should not be used as limits for normal device operation. Exposure to absolute maximum rating conditions for an extended period of time can affect device reliability.

## 12.2.2 Recommended Operating Conditions

| Symbol | Parameter                                                       | Min | Typ | Max | Units |
|--------|-----------------------------------------------------------------|-----|-----|-----|-------|
| $T_a$  | Operating Temperature Range Commercial (Ambient; 0 CFS airflow) | 0   |     | 55  | °C    |
| $T_j$  | Junction Temperature                                            |     |     | 105 | °C    |

**Notes:**

1. For normal device operation, adhere to the limits in this table. Sustained operation of a device at conditions exceeding these values, even if they are within the absolute maximum rating limits, can result in permanent device damage or impaired device reliability. Device functionality to stated DC and AC limits is not guaranteed if conditions exceed recommended operating conditions.
2. Recommended operation conditions require accuracy of power supply of  $\pm 5\%$  relative to the nominal voltage.
3. External Heat Sink (EHS) is needed.
4. Refer to [Section 14.0](#) for a description of the allowable thermal environment.

## 12.3 Power Delivery

### 12.3.1 Power Delivery Definitions

- **DC Voltage Regulation** — DC accuracy with respect to the nominal voltage specification. Includes controller feedback accuracy and resistive losses in the power distribution network.
- **AC Voltage Regulation** — Minimum/maximum noise voltage based on mid-to-high frequency ( $\sim 1$ -20 MHz) AC load currents (excluding ripple voltage). Note that this specification is met by following the system design recommendations/considerations related to the recommended decoupling design (see [Section 13.0](#)).
- **Total Line Regulation** — The sum of DC and AC voltage regulation.

### 12.3.2 Power Supply Specifications

| Description                    | Parameter                               |
|--------------------------------|-----------------------------------------|
| <b>VCC3P3V</b>                 |                                         |
| Nominal Voltage                | 3.3 V                                   |
| DC Voltage Regulation          | $\pm 5\%$ DC Regulation                 |
| AC Voltage Regulation          | $\pm 4\%$ AC Regulation (132 mV Pk-Pk)  |
| Total Line Regulation          | $\pm 9\%$                               |
| <b>VCC2P1</b>                  |                                         |
| Nominal Voltage                | 2.1 V                                   |
| DC Voltage Regulation          | $\pm 3\%$ DC Regulation                 |
| AC Voltage Regulation          | $\pm 0.6\%$ AC Regulation (13 mV Pk-Pk) |
| Total DC/AC Voltage Regulation | $\pm 3.6\%$                             |
| Step Load Size                 | 64 mA                                   |
| Step Load Slew Rate $di/dt$    | 200 mA/1 $\mu$ s                        |

| Description                    | Parameter                          |
|--------------------------------|------------------------------------|
| <b>VCC1P2</b>                  |                                    |
| Nominal Voltage                | 1.2 V                              |
| DC Voltage Regulation          | ± 3% DC Regulation                 |
| AC Voltage Regulation          | ± 2% AC Regulation (24 mV Pk-Pk)   |
| Total DC/AC Voltage Regulation | ± 5%                               |
| Step Load Size                 | 125 mA                             |
| Step Load Slew Rate di/dt      | 125 mA/1 µs                        |
| <b>VCC0P83</b>                 |                                    |
| Nominal Voltage                | 0.83 V                             |
| DC Voltage Regulation          | ± 3% DC Regulation                 |
| AC Voltage Regulation          | ± 2% AC Regulation (16.6 mV Pk-Pk) |
| Total DC/AC Voltage Regulation | ± 5%                               |
| Step Load Size                 | 2 A                                |
| Step Load Slew Rate di/dt      | 587 mA/1 µs                        |

### 12.3.3 VCC3P3 External Power Supply Specification (3.3 V)

| Parameter                        | Description                                                                                                                                                              | Min | Max   | Units |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|-------|-------|
| Rise Time                        | Time from 10% to 90% mark.                                                                                                                                               | 0.1 | 50    | ms    |
| Monotonicity                     | Voltage dip allowed in ramp.                                                                                                                                             | N/A | 0     | mV    |
| Slope                            | Ramp rate at any given time between 10% and 90%.<br>Min = $0.8 \cdot V(\text{min}) / \text{rise time (max)}$<br>Max = $0.8 \cdot V(\text{max}) / \text{rise time (min)}$ | 48  | 28800 | V/S   |
| Operational Range                | Voltage range for normal operating conditions.                                                                                                                           | 3   | 3.6   | V     |
| Overshoot                        | Maximum overshoot allowed.                                                                                                                                               | N/A | 100   | mV    |
| Overshoot Settling Time          | Maximum overshoot allowed duration.<br><b>Note:</b> At that time delta voltage should be lower than 5 mV from steady state voltage.                                      | N/A | 0.05  | ms    |
| Suggested Decoupling Capacitance | Capacitance range.                                                                                                                                                       | 25  | N/A   | µF    |

### 12.3.4 VCC2P1 External Power Supply Specification (2.1 V)

| Title                            | Description                                                                                                                                                             | Min | Max   | Units         |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|-------|---------------|
| Rise Time                        | Time from 10% to 90% mark.                                                                                                                                              | 0.1 | 50    | ms            |
| Monotonicity                     | Voltage dip allowed in ramp.                                                                                                                                            | N/A | 0     | mV            |
| Slope                            | Ramp rate at any given time between 10% and 90%<br>Min = $0.8 \cdot V(\text{min}) / \text{rise time (max)}$<br>Max = $0.8 \cdot V(\text{max}) / \text{rise time (min)}$ | 32  | 17600 | V/S           |
| Operational Range                | Voltage range for normal operating conditions.                                                                                                                          | 2.0 | 2.2   | V             |
| Overshoot                        | Maximum overshoot allowed.                                                                                                                                              | N/A | 100   | mV            |
| Overshoot Settling Time          | Maximum overshoot allowed duration.<br><b>Note:</b> At that time delta voltage should be lower than 5 mV from steady state voltage.                                     | N/A | 0.1   | ms            |
| Suggested Decoupling Capacitance | Capacitance range.                                                                                                                                                      | 200 | N/A   | $\mu\text{F}$ |

### 12.3.5 VCC1P2 External Power Supply Specification (1.2 V)

| Title                            | Description                                                                                                                                                             | Min  | Max   | Units         |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|---------------|
| Rise Time                        | Time from 10% to 90% mark.                                                                                                                                              | 0.1  | 50    | ms            |
| Monotonicity                     | Voltage dip allowed in ramp.                                                                                                                                            | N/A  | 0     | mV            |
| Slope                            | Ramp rate at any given time between 10% and 90%<br>Min = $0.8 \cdot V(\text{min}) / \text{rise time (max)}$<br>Max = $0.8 \cdot V(\text{max}) / \text{rise time (min)}$ | 18   | 10080 | V/S           |
| Operational Range                | Voltage range for normal operating conditions.                                                                                                                          | 1.14 | 1.26  | V             |
| Overshoot                        | Maximum overshoot allowed.                                                                                                                                              | N/A  | 60    | mV            |
| Overshoot Duration               | Maximum overshoot allowed duration.<br><b>Note:</b> At that time delta voltage should be lower than 5 mV from steady state voltage.                                     | 0.0  | 0.05  | ms            |
| Suggested Decoupling Capacitance | Capacitance range.                                                                                                                                                      | 200  | N/A   | $\mu\text{F}$ |

## 12.3.6 VCC0P83 External Power Supply Specification (0.83 V)

| Title                            | Description                                                                                                                                                             | Min   | Max   | Units         |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|-------|---------------|
| Rise Time                        | Time from 10% to 90% mark.                                                                                                                                              | 0.1   | 20    | ms            |
| Monotonicity                     | Voltage dip allowed in ramp.                                                                                                                                            | N/A   | 0     | mV            |
| Slope                            | Ramp rate at any given time between 10% and 90%<br>Min = $0.8 \cdot V(\text{min}) / \text{rise time (max)}$<br>Max = $0.8 \cdot V(\text{max}) / \text{rise time (min)}$ | 13    | 7136  | V/S           |
| Operational Range                | Voltage range for normal operating conditions.                                                                                                                          | 0.788 | 0.871 | V             |
| Overshoot                        | Maximum overshoot allowed.                                                                                                                                              | N/A   | 40    | mV            |
| Overshoot Duration               | Maximum overshoot allowed duration.<br><b>Note:</b> At that time delta voltage should be lower than 5 mV from steady state voltage.                                     | N/A   | 0.05  | ms            |
| Suggested Decoupling Capacitance | Capacitance range.                                                                                                                                                      | 500   | N/A   | $\mu\text{F}$ |

## 12.3.7 Power On/Off Sequence

3.3 V should be powered on at 90% before any other rails.

The following power-up sequence is recommended for the X550.

**Figure 12-1. Power On/Off Sequence Flow**

**Table 12-1. Notes for Power On/Off Sequence Diagram**

| Note | Description                                                                                                                           |
|------|---------------------------------------------------------------------------------------------------------------------------------------|
| 1    | The 2.1 V rail does not start to ramp before the 3.3 V rail is 80% of its final value.                                                |
| 2    | The 1.2 V rail does not start to ramp before the 2.1 V rail is 80% of its final value. Tmax(2.1 V to 1.2 V) should be less than 5 ms. |
| 3    | The 0.83 V rail does not start to ramp before the 1.2 V rail is 80% of its final value.                                               |
| 4    | Tramp for each power rail, as defined in sections 12.3.3 to 12.3.6.                                                                   |
| 5    | Total power-up time from the start of the 3.3 V rail raising until the 0.83 V rail gets to its final level is < 170 ms.               |
| 6    | When powering off, all power rails must get to a 0 V level within 20 ms from the point the first power rail starts powering off.      |

## 12.3.8 Power On Reset

The X550 internal power-on reset circuitry initiates a full chip reset when voltage levels of power supplies reach certain thresholds at power-up.

| Symbol       | Parameter                                | Specification |     |       | Units |
|--------------|------------------------------------------|---------------|-----|-------|-------|
|              |                                          | Min           | Typ | Max   |       |
| 2.1 V        | Threshold for 2.1 Vdc supply in power-up | 1.7           |     | 1.8   | Vdc   |
| 1.2 V        | Threshold for 1.2 Vdc supply in power-up | 0.931         |     | 0.989 | Vdc   |
| 0.83 V       | Threshold for 0.8 Vdc supply in power-up | 0.563         |     | 0.597 | Vdc   |
| LAN_PWR_GOOD | High-threshold (VIH)                     | 0.83          |     | 3.6   | Vdc   |
| LAN_PWR_GOOD | Low-threshold (VIL)                      | 0.3           |     | 0.36  | Vdc   |

## 12.3.9 Current Consumption

- Power numbers are based on measurement data.
- Maximum power mode: 3 sigma FAST material, Vnom, Tj-max (105 °C).
- Other operational modes: Typical material, Vnom.
- Unless stated otherwise, the power consumption below is based on a PCIe Gen3 x4 connection for the X550-AT and the X550-AT2, and PCIe Gen2 x8 for the X550-BT2.

**Table 12-2. X550-AT Power Consumption**

| Operating Mode <sup>1</sup> | 3.3 V        |            | 2.1 V        |            | 1.2 V        |            | 0.83 V       |            | Device Total |
|-----------------------------|--------------|------------|--------------|------------|--------------|------------|--------------|------------|--------------|
|                             | Current (mA) | Power (mW) | Current (mA) | Power (mW) | Current (mA) | Power (mW) | Current (mA) | Power (mW) | Power (W)    |
| 10 GbE Max                  | 194          | 640.2      | 623          | 1308.3     | 928          | 1113.6     | 6347         | 5268.01    | 7.84         |
| 10 GbE Max 30 m Reach       | 192          | 633.6      | 639          | 1341.9     | 968          | 1161.6     | 5180         | 4299.4     | 6.94         |
| 10 GbE Idle                 | 193          | 636.9      | 622          | 1306.2     | 844          | 1012.8     | 5018         | 4164.94    | 6.63         |
| 10 GbE 3 m reach            | 192          | 633.6      | 604.31       | 1269.06    | 838.9        | 1006.68    | 4765.62      | 3955.46    | 6.37         |
| 5 GbE                       | 192          | 633.6      | 598.86       | 1257.6     | 763.7        | 916.44     | 3511.2       | 2914.3     | 5.23         |
| 2.5 GbE                     | 194          | 640.2      | 590.18       | 1239.37    | 808.31       | 969.98     | 2215.24      | 1838.65    | 4.19         |
| 1 GbE                       | 192          | 633.6      | 622          | 1306.2     | 802          | 962.4      | 1500         | 1245       | 3.65         |
| 100 Mb/s                    | 193          | 636.9      | 435          | 913.5      | 680          | 816        | 1294         | 1074.02    | 2.95         |
| 1 GbE WoL                   | 192          | 633.6      | 616          | 1293.6     | 639          | 766.8      | 976          | 810.08     | 3.01         |
| 100 Mb/s WoL                | 191          | 630.3      | 436          | 915.6      | 531          | 637.2      | 767          | 636.61     | 2.32         |

1. Max defined as 105 °C Tj and 3 sigma FAST silicon. All others measured at 80 °C and typical silicon.

**Table 12-3. X550-AT2 Power Consumption**

| Operating Mode <sup>1</sup>  | 3.3 V        |            | 2.1 V        |            | 1.2 V        |            | 0.83 V       |            | Device Total |

1. Max defined as 105 °C Tj and 3 sigma FAST silicon. All others measured at 80 °C and typical silicon.

## 12.3.10 Peak Current Consumption

### 12.3.10.1 Aux Power on Peak Current Consumption

Conditions:

- 3 sigma FAST material
- Vnom
- $T_j = 80\text{ }^{\circ}\text{C}$
- 100 Mb/s link

| 3.3 V  | 2.1 V | 1.2 V | 0.83 V |
|--------|-------|-------|--------|
| 400 mA | 1.2 A | 1.6 A | 6 A    |

### 12.3.10.2 Main Power on Peak Current Consumption During 10GBASE-T Training

Conditions:

- 3 sigma FAST material
- Vnom
- $T_j = 105\text{ }^{\circ}\text{C}$  (max)
- 10 Gb/s link

| 3.3 V  | 2.1 V | 1.2 V | 0.83 V |
|--------|-------|-------|--------|
| 400 mA | 1.5 A | 2 A   | 13 A   |

## 12.4 DC/AC Specifications

### 12.4.1 Digital Functional 3.3 V I/O DC Electrical Characteristics

**Table 12-5. Digital I/O LAN\_PWR\_GOOD**

| Symbol          | Parameter                                           | Description | Min   | Typ  | Max  | Units |
|-----------------|-----------------------------------------------------|-------------|-------|------|------|-------|
| VIH             | Input High Voltage                                  |             | 0.84  |      | 3.60 | V     |
| VIL             | Input Low Voltage                                   |             | -0.30 |      | 0.36 | V     |
| VT              | Threshold Point                                     |             |       | 0.60 |      | V     |

| Cload  | Pin Capacitance       |                                  |      | 5   | pF    |      |

**Note:** Table 12-9 applies to AUX\_PWR, MAIN\_PWR\_OK, LAN1\_DIS\_N, LAN0\_DIS\_N, BYPASS\_POR, ENCRYPTION\_EN, and PE\_RST\_N.

## 12.4.2 Open Drain I/Os

**Table 12-10. Open Drain I/Os**

| Symbol   | Parameter                    | Condition                              | Min | Max | Units | Note |
|----------|------------------------------|----------------------------------------|-----|-----|-------|------|
| Vih      | Input High Voltage           |                                        | 2.1 |     | V     |      |
| Vil      | Input Low Voltage            |                                        |     | 0.8 | V     |      |
| Ileakage | Output Leakage Current       | $0 \leq V_{in} \leq V_{CC3P3}$ maximum |     | ±10 | μA    | 2    |
| Vol      | Output Low Voltage           | @ Ipullup = 4 mA                       |     | 0.4 | V     | 5    |
| Ipullup  | Current Sinking              | Vol = 0.4 V                            | 4   |     | mA    |      |
| Cin      | Input Pin Capacitance        |                                        |     | 7   | pF    | 3    |
| Cload    | Maximum Load Pin Capacitance |                                        |     | 30  | pF    | 4    |
| Ioffsm   | Input leakage Current        | VCC3P3 off or floating                 |     | ±10 | μA    | 2    |

**Notes:**

1. Section 12.4.2 applies to SMBD, SMBCLK, SMBALRT\_N, PE\_WAKE\_N.
2. Device must meet this specification whether powered or un-powered.
3. Characterized, not tested.
4. Cload should be calculated according to the external pull-up resistor and the frequency.
5. OD no high output drive. VOL max=0.4 V at 16 mA, VOL max=0.2 V at 0.1 mA.

The buffer specification meets the SMBus specification requirements defined at: [www.smbus.org](http://www.smbus.org).

## 12.4.3 NC-SI I/O DC Specification

**Table 12-11. NC-SI I/O DC Specification**

| Symbol            | Parameter                                                  | Conditions                                                  | Min. | Typ. | Max   | Units |
|-------------------|------------------------------------------------------------|-------------------------------------------------------------|------|------|-------|-------|
| Vref <sup>1</sup> | Bus High Reference                                         |                                                             | 3.0  | 3.3  | 3.46  | V     |

| Iz                | Leakage Current for Output Signals in High-Impedance State | 0 ≤ Vin ≤ Vih <sub>max</sub><br>@Vref = Vref <sub>max</sub> | -20  |      | 20    | μA    |

**Notes:**

1. Vref = Bus high reference level. This parameter replaces the term supply voltage since actual devices can have internal mechanisms that determine the operating reference for the sideband interface that are different from the device's overall power supply inputs. Vref is a reference point that is used for measuring parameters such as overshoot and undershoot and for determining limits on signal levels that are generated by a device. To facilitate system implementations, a device must provide a mechanism (such as a power supply pin, internal programmable reference, or reference level pin) to enable Vref to be set to within 20 mV of any point in the specified Vref range. This is to enable a system integrator to establish an interoperable Vref level for devices on the sideband interface. Although the NC-SI specification define the Vrefmax up to 3.6 V, the X550 supports the Vrefmax up to 3.46 V (3.3 V +5%).
2. [Section 12.4.3](#) applies to NCSI\_CLK\_IN, NCSI\_CRSDV, NCSI\_RXD[1:0], NCSI\_TX\_EN and NCSI\_TXD[1:0], NCSI\_ARB\_IN, NCSI\_ARB\_OUT.
3. Refer to the *Network Controller Sideband Interface (NC-SI) Specification* for more details.

## 12.4.4 Digital I/F AC Specifications

### 12.4.4.1 Digital I/O AC Electrical and Timing Characteristics

**Table 12-12. Digital 3.3 V I/O AC Specifications — SDP**

| Parameters          | Description | Min | Max     | Condition | Notes |
|---------------------|-------------|-----|---------|-----------|-------|
| $f_{\text{symbol}}$ | Symbol Rate |     | 25 MS/s |           |       |

### 12.4.4.2 Digital 3.3 V I/O AC Specifications — JTAG AC Specifications

**Table 12-13. JTAG I/F Timing Parameters**

| Symbol            | Parameter                | Min | Typ | Max | Unit |
|-------------------|--------------------------|-----|-----|-----|------|
| $t_{\text{jclk}}$ | JTCK clock frequency     |     |     | 10  | MHz  |
| $t_{\text{jh}}$   | JTMS and JTDI hold time  | 10  |     |     | ns   |
| $t_{\text{jsu}}$  | JTMS and JTDI setup time | 10  |     |     | ns   |
| $t_{\text{jpr}}$  | JTDO propagation delay   |     |     | 15  | ns   |

**Notes:**

1. Table 12-13 applies to JTCK, JTMS, JTDI and JTDO.
2. Timing measured relative to JTCK reference voltage of VCC3P3/2.

**Figure 12-2. JTAG AC Timing Diagram**

### 12.4.4.3 SMBus AC Specifications

The X550 meets the SMBus AC specification of 100 KHz as defined in SMBus specification, Version 2, Section 3.1.1 (<http://www.smbus.org/specs/>).

The X550 also supports a 400 KHz SMBus (as an input clock from the MC and as a slave). The X550 meets the 100 KHz, 400 KHz, and 100 MHz specifications listed in Table 12-14.

**Table 12-14. SMBus Timing Parameters (Master Mode)**

| Symbol               | Parameter                                                                         | Min  | Typ<br>100 KHz <sup>1</sup> | Typ<br>400 KHz <sup>2</sup> | Typ<br>1 MHz <sup>3,4</sup> | Max  | Units |
|----------------------|-----------------------------------------------------------------------------------|------|-----------------------------|-----------------------------|-----------------------------|------|-------|
| F <sub>SMB</sub>     | SMBus Frequency                                                                   |      | 100                         | 400                         | 1000                        | 1000 | KHz   |

#### 12.4.4.4 Flash AC Specification

The X550 is designed to support a serial Flash. For Flash I/F timing specifications, see [Table 12-16](#) and [Figure 12-4](#).

Table 12-16. Flash I/F Timing Parameters from Supported Flash Devices

| Symbol   | Parameter                                                  | Min | Max | Units |
|----------|------------------------------------------------------------|-----|-----|-------|
| fSCK     | Serial Clock (SCK) Frequency                               |     | 25  | MHz   |
| fRDLF    | SCK Frequency for Read Array (Low Frequency - 0x03 Opcode) |     | 25  | MHz   |
| tSCKH    | SCK High Time                                              | 16  |     | ns    |
| tSCKL    | SCK Low Time                                               | 16  |     | ns    |
| tSCKR(1) | SCK Rise Time - Peak-to-Peak (Slew Rate)                   | 0.1 |     | V/ns  |
| SCKF(1)  | SCK Fall Time - Peak-to-Peak (Slew Rate)                   | 0.1 |     | V/ns  |
| tCSH     | Chip Select High Time                                      | 25  |     | ns    |
| tCSLS    | Chip Select Low Setup Time (Relative to SCK)               | 10  |     | ns    |
| tCSLH    | Chip Select Low Hold Time (Relative to SCK)                | 10  |     | ns    |
| tCSHS    | Chip Select High Setup Time (Relative to SCK)              | 10  |     | ns    |
| tCSHH    | Chip Select High Hold Time (Relative to SCK)               | 10  |     | ns    |
| tDS      | Data In Setup Time                                         | 5   |     | ns    |
| tDH      | Data In Hold Time                                          | 5   |     | ns    |
| tDIS(1)  | Output Disable Time                                        |     | 15  | ns    |
| tV(2)    | Output Valid Time                                          |     | 15  | ns    |
| tOH      | Output Hold Time                                           | 1   |     | ns    |

Figure 12-4. Serial Input Timing

Figure 12-5. Serial Output Timing

### 12.4.4.5 NC-SI AC Specifications

The X550 supports the NC-SI standard as defined in the Network Controller Sideband Interface (NC-SI) specification. The NC-SI timing specifications can be found in [Table 12-17](#) and [Figure 12-6](#).

**Table 12-17. NC-SI Interface AC Specifications**

| Parameter                                                                                             | Symbol    | Conditions | Min | Typ | Max        | Units | Notes |
|-------------------------------------------------------------------------------------------------------|-----------|------------|-----|-----|------------|-------|-------|
| REF_CLK Frequency                                                                                     |           |            |     | 50  | 50+100 ppm | MHz   |       |
| REF_CLK Duty Cycle                                                                                    |           |            | 35  |     | 65         | %     | 2     |
| Clock-to-Out[1]<br>(10pF<=load<=50 pF)                                                                | Tco       |            | 2.5 |     | 12.5       | ns    | 1,3   |
| Skew Between Clocks                                                                                   | Tskew     |            |     |     | 1.5        | ns    |       |
| TXD[1:0], TX_EN, RXD[1:0],<br>CRS_DV, RX_ER, ARB_IN,<br>ARB_OUT Data Setup to<br>REF_CLK Rising Edge  | Tsu       |            | 3   |     |            | ns    | 3     |
| TXD[1:0], TX_EN, RXD[1:0],<br>CRS_DV, RX_ER, ARB_IN,<br>ARB_OUT Data Hold From<br>REF_CLK Rising Edge | Thd       |            | 1   |     |            | ns    | 3     |
| Signal Rise/Fall Time                                                                                 | Tr/Tf     |            | 1   |     | 6          | ns    | 4     |
| REF_CLK Rise/Fall Time                                                                                | Tckr/Tckf |            | 0.5 |     | 3.5        | ns    |       |

**Notes:**

1. This timing relates to the output pins timing while Tsu and Thd relate to timing at the input pins.
2. REF\_CLK duty cycle measurements are made from Vckm to Vckm; middle point (50% of Vref in [Section 12.4.3](#)). Clock skew Tskew is measured from Vckm to Vckm of two NC-SI devices and represents maximum clock skew between any two devices in the system.
3. All timing measurements are made between Vckm and Vm; middle point (50% of Vref in [Section 12.4.3](#)). All output timing parameters are measured with a capacitive load between 10 pF and 50 pF.
4. Rise and fall time are measured between points that cross 10% and 90% of Vref (see [Figure 12-6](#)). The middle points (50% of Vref) are marked as Vckm and Vm for clock and data, respectively.

**Figure 12-6. NC-SI AC Specification**

### 12.4.4.6 Reset Signals

For power-on indication, the X550 can either use an internal power-on circuit, which monitors the 2.1 V, 1.2 V, and 0.83 V power supply, or external reset using the LAN\_PWR\_GOOD pad.

**Table 12-18. POR Configuration**

| Parameter    | LAN_PWR_GOOD |
|--------------|--------------|
| Internal POR | High         |
| External POR | Reset Signal |

The timing between the power-up sequence and the different reset signals when using the internal power indication is described in [Section 12.3.8](#).

#### 12.4.4.6.1 External Power-On Reset

The X550 may use the LAN\_PWR\_GOOD pad as power-on indication. [Table 12-19](#) lists the timing for the external power-on signal.

**Table 12-19. External Reset Specification**

| Symbol | Title                      | Description                                                                  | Min | Max | Units |
|--------|----------------------------|------------------------------------------------------------------------------|-----|-----|-------|
| Tlpgw  | LAN_PWR_GOOD Minimum Width | Minimum width for LAN_PWR_GOOD.                                              | 5   | N/A | μs    |
| Tlpg   | LAN_PWR_GOOD High Hold     | Hold time following power-up (power supplies in acceptable operating range). | 40  | 80  | ms    |

**Figure 12-7. External Reset Timing Diagram**

### 12.4.5 PCIe Interface AC/DC Specification

The X550 PCIe interface supports the electrical specifications defined in:

- PCI Express\* 2.0 Card Electromechanical Specification.
- PCI Express\* 3.0 Base Specification, Chapter 4.

### 12.4.6 Network Interface AC/DC Specification

The AC/DC specification of the network interface is according to the 10GBASE-T, 1000BASE-T, and 100BASE-TX Standards (802.3, 802.3an, and 802.3u, respectively), and the and NBASE-T specification. The 100BASE-T parameters are also described in standard ANSI X3.263.

## 12.5 Thermal Diode

The X550 incorporates an on-die diode that can be used to monitor the die temperature (junction temperature). An external thermal sensor located on the motherboard or a stand-alone measurement device can also be used to monitor the die temperature of the X550 for thermal management or characterization. [Table 12-20](#) lists the parameters that pertain to the X550's thermal diode pins (THERM\_D1\_P, THERM\_D1\_N).

**Table 12-20. Thermal Diode Parameters**

| Symbol         | Min. | Typical | Max  | Unit | Notes |
|----------------|------|---------|------|------|-------|
| I forward bias | 50   | 100     | 1000 | μA   | 1     |
| n_ideality     | 1.03 | 1.05    | 1.08 |      | 3     |
| ESR            |      | 2.77    |      | Ω    | 2     |

**Notes:**

1. Intel does not support or recommend operation of the thermal diode under reverse bias.
2. ESR: Effective Series Resistance - needed for various TD measurement tools.
3. n\_ideality is the diode ideality factor parameter, as represented by the diode equation:

$$I = I_0 \left( e^{\frac{eV_D}{nkT}} - 1 \right)$$

**Note:** The X550's thermal diode has a -10 °C offset from the Tj at the center of the die. An external thermal sensor should add this offset for accurate measurement.

## 12.6 Crystal Specification

| Parameter Name                     | Symbol          | Recommended Value                           | Conditions |
|------------------------------------|-----------------|---------------------------------------------|------------|
| Frequency                          | $f_o$           | 50.000 MHz                                  | @25 °C     |
| Vibration Mode                     |                 | Fundamental                                 |            |
| Cut                                |                 | AT                                          |            |
| Operating /Calibration Mode        |                 | Parallel                                    |            |
| Frequency Tolerance @25 °C         | $Df/f_o$ @25 °C | ±10 ppm / ±15 ppm (see note)                | @25 °C     |
| Temperature Tolerance              | $Df/f_o$        | ±10 ppm ±15 ppm (see note)                  |            |
| Operating Temperature              | $T_{opr}$       | 0 to +70 °C                                 |            |
| Non Operating Temperature Range    | $T_{opr}$       | -40 to +90 °C                               |            |
| Equivalent Series Resistance (ESR) | $R_s$           | 50 $\Omega$ maximum                         | @50 MHz    |
| Load Capacitance                   | $C_{load}$      | 16 pF                                       |            |
| Shunt Capacitance                  | $C_o$           | <5 pF maximum                               |            |
| Max Drive Level                    | $D_L$           | 300 $\mu$ W                                 |            |
| Insulation Resistance              | IR              | 500 M $\Omega$ minimum                      | @ 100 Vdc  |
| Aging                              | $Df/f_o$        | (±5 ppm/year) / (±2 ppm/year)<br>(see note) |            |
| CL1/CL2                            |                 | 18 pF                                       |            |

**Note:** To provide some flexibility in the Bill Of Materials (BOM), two options are supported:

- Crystal parameters option 1:
  - Frequency tolerance @ 25 °C ±15 ppm
  - Temperature tolerance ±15 ppm
  - Aging ±2 ppm/year
- Crystal parameters option 2:
  - Frequency tolerance @ 25 °C ±10 ppm
  - Temperature tolerance ±10 ppm
  - Aging ±5 ppm/year

**Figure 12-8. Crystal Specification Schematic**

## 12.7 Package

### 12.7.1 Mechanical

The X550 is assembled into a 25x25 mm X540 layout-compatible FCBG package with a 10-layer substrate, or to a 17x17 mm package with a 6-layer substrate.

| Body Size | Ball Count | Ball Pitch | Substrate |
|-----------|------------|------------|-----------|
| 25x25 mm  | 576        | 1.0 mm     | 10 layers |
| 17x17 mm  | 256        | 1.0 mm     | 6 layers  |

### 12.7.2 Thermal

For the X550's package thermals please refer to [Section 14.0](#).

### 12.7.3 Electrical

Package electrical models are part of the IBIS files.

## 12.7.4 Mechanical Package Diagram

Figure 12-9. X550-AT2

Table 12-21. X550-AT2 - Discrete Components

| Item No. | X     | Y     | Z (Height) | Component Type |
|----------|-------|-------|------------|----------------|
| CO1      | -6.70 | -5.00 | 0.56       | 0402           |
| CO2      | 6.62  | -4.80 | 0.56       | 0402           |
| CO3      | -6.90 | 3.515 | 0.90       | 0603           |
| CO4      | 6.90  | 3.515 | 0.90       | 0603           |

| Item No. | X     | Y     | Z<br>(Height) | Component<br>Type |
|----------|-------|-------|---------------|-------------------|
| CO1      | -6.90 | 2.485 | 0.90          | 0603              |
| CO2      | 6.90  | 2.485 | 0.90          | 0603              |

## 13.0 Design Considerations and Guidelines

---

This section provides guidelines for selecting components, connecting interfaces, using special pins, and layout guidance.

Unused interfaces should be terminated with pull-up or pull-down resistors. These are indicated in [Section 2.0](#) or reference schematics. There are reserved pins, identified as RSVD\_NC and RSVD\_VSS. The X550 might enter special test modes unless these strapping resistors are in place.

Some unused interfaces must be left open. Do not attach pull-up or pull-down resistors to any balls identified as No Connect or Reserved No Connect.

### 13.1 Connecting the PCIe Interface

The X550 connects to the host system using a PCIe interface. The interface can be configured to operate in several link modes as detailed in [Section 3.0](#). A link between the ports of two devices is a collection of lanes. Each lane has to be AC-coupled between its corresponding transmitter and receiver, with the AC-coupling capacitor located close to the transmitter side (within 1 inch). Each end of the link is terminated on the die into nominal 100 differential DC impedance. Board termination is not required.

Refer to the *PCI Express\* Base Specification, Revision 3.0* and *PCI Express\* Card Electromechanical Specification, Revision 2.0*.

#### 13.1.1 Link Width Configuration

The X550 supports link widths of x8, x4, or x1 as determined by the Flash *Lane\_Width* field in the PCIe initialization configuration. The configuration is loaded using bits 9:4 in the *Max Link Width* field of the Link Capabilities register (0xAC); default setting is 0x08. The X550-AT2 default link width is x4. The X550-BT2 default link width is x8.

During link configuration, the platform and the X550 negotiate a common link width. For proper operation, the selected maximum number of PCIe lanes must be connected to the host system.

#### 13.1.2 Polarity Inversion and Lane Reversal

To ease routing, designers have the flexibility to the lane reversal modes supported by the X550. Polarity inversion can also be used, since the polarity of each differential pair is detected during the link training sequence.

When lane reversal is used, some of the down-shift options are not available. For a description of available combinations, see [Section 3.0](#).

### 13.1.3 PCIe Reference Clock

The X550 requires a 100 MHz differential reference clock called PE\_CLK\_p and PE\_CLK\_n. These signals are typically generated on the system board and routed to the PCIe connector. For add-in cards, the clock is furnished at the PCIe connector.

**Note:** The frequency tolerance for the PCIe reference clock is +/- 300 ppm.

### 13.1.4 Bias Resistor

For proper biasing of the PCIe analog interface, a 4.75 K $\Omega$  0.1% resistor needs to be connected between PE\_RSENSE and PE\_RBIAS. To avoid noise coupled onto this reference signal, place the bias resistor close to the X550 and keep traces as short as possible.

### 13.1.5 Miscellaneous PCIe Signals

The X550 signals power management events to the system by pulling low the PE\_WAKE\_N signal. This signal operates like the PCI PME# signal. Note that somewhere in the system, this signal has to be pulled high to the auxiliary 3.3 V supply rail.

The PE\_RST# signal, which serves as the familiar reset function for the X550, needs to be connected to the host system's corresponding signal.

### 13.1.6 PCIe Layout Recommendations

For information regarding the PCIe signal routing, refer to the *Intel PCIe Design Guide*.

## 13.2 Connecting the 10GBASE-T MDI Interfaces

In 10GBASE-T mode, the line interface on the X550 is capable of driving up to 100 meters of CAT-6a unshielded twisted pair or 100 meters of CAT-7 shield cable (100  $\Omega$  differential impedance). It can also drive 55 meters of CAT-6 cable. In 100BASE-TX and 100MBASE-TX modes, it can drive 130 meters of CAT-5e (or better) cable. It is designed to drive this via a quad, 50  $\Omega$  center tapped 1:1 transformer connected to an RJ-45 PCB-mount jack. Solutions that combine the transformer and RJ-45 jack into a single device are also supported.

The line interface on the X550 supports automatic A/B and C/D pair swaps and inversions (MDI-X). It also supports provisioned ABCD to DCBA pair reversal for ease of routing via an NVM setting, which sets this configuration at power up.

**Note:** This reversal does not swap polarities thus A+ maps to D+, etc.

## 13.2.1 MDI Circuit Guidelines

The MDI discrete design and integrated magnetic components were chosen for inclusion in the reference design and Bill of Material (BOM). Refer to [Section 13.13](#) for more details. These components are capable of delivering the performance required for this demanding application.

## 13.2.2 Magnetics Module

The magnetics module has a critical effect on overall IEEE and emissions conformance. The X550 should meet the performance required for a design with reasonable margin to allow for manufacturing variation. Carefully qualifying new magnetics modules prevents problems that might arise because of interactions with other components or the Printed Circuit Board (PCB) itself. The magnetics specified should comply with the specifications listed in the Intel® 10-GBASE-T Magnetic Specification Electrical/Mechanical Requirements for 10GBASE-T Magnetic Components, which includes separate specifications for discrete and integrated magnetics modules.

These have five channels of 3-wire choke / transformer pairs in them, with four facing the choke towards the line (RJ45), and one facing the choke towards the X550.

The steps involved in magnetics module qualification are:

1. Verify that the vendor's published specifications in the component datasheet meet or exceed the required IEEE 802.3an specifications and the internal specifications listed in the Intel® 10-GBASE-T Magnetic Specification Electrical/Mechanical Requirements for 10GBASE-T Magnetic Components.
2. Independently measure the component's electrical parameters on a test bench, checking samples from multiple lots. Check that the measured behavior is consistent from sample-to-sample and that measurements meet the published specifications.
3. Perform physical layer conformance testing and EMC (FCC and EN) testing in real systems. Vary temperature and voltage while performing system level tests.

Magnetics modules for 10GBASE-T Ethernet as used by the X550 are similar to those designed for 1GBASE-T, except that the electrical requirements for the board layout and magnetics are more stringent. Refer to [Section 12.0](#) for specific electrical requirements that the magnetics need to meet.

## 13.2.3 5th Channel

To sense and cancel common-mode noise, the X550 provides a 5th channel designed for this purpose. It is very similar to the receivers on Pairs A - D, with the exception that it does not have a driver and only receives. Its input impedance is 100  $\Omega$ .

When discrete magnetics are in use, this channel should be connected to a common-mode sense point. In this design, the common-mode sense point is the Bob Smith termination of Pair D. This sense point is run through a transformer to convert the signal to differential for pick-up by the 5th channel receiver. To match the 100  $\Omega$  impedance of the receiver input with the required 75  $\Omega$  Bob Smith termination, a 300  $\Omega$  parallel resistor is used.

Integrated magnetics perform the required termination internally. As a result, the Bob Smith termination used in the discrete case is not necessary.

If a different choice of magnetics is required they should comply with the specifications listed in [Section 13.13](#).

## 13.2.4 Board Noise Cancellation

An advantage of the 5th channel is that in addition to canceling received common-mode interference from the line, it also cancels noise picked up on the PCB. This is especially important if the RJ-45 is located any significant distance from the X550. Consequently, every effort should be made to route the 5th channel traces along the same path as the other four MDI traces.

## 13.2.5 MDI Layout Guidance

The MDI that was chosen for X550 designs consist of an RJ-45 right-angle PCB jack, Bob Smith termination and discrete magnetics (see [Figure 13-1](#)). The magnetics can be implemented either as a discrete module or an integrated solution combining the magnetics and the RJ-45 jack.

Minimizing the amount of space needed for the PHY is important because other interfaces compete for physical space on a Network Interface Card (NIC) or LAN on Motherboard (LOM) near the connector. The PHY circuits need to be as close as possible to the connector.

[Figure 13-1](#) illustrates some basic placement distance guidelines. It shows four differential pairs and the layout can be generalized for a 10 GbE system with four analog pairs. The ideal placement for the X550 is approximately two inches behind the magnetics module for both the discrete and integrated solutions.

### 13.2.5.1 Discrete Magnetics

The X550 uses a common-mode sensing circuit on the MDI of each channel to cancel in-band common-mode interference that couples into the differential receive signals. This common-mode sense circuitry is referred to as the 5th channel. This is where the sense circuitry sits in series with the Bob Smith termination for Channel D. The signal runs through a transformer to perform the common-to-differential conversion where it is followed by the X550-facing common-mode choke. This provides isolation from board noise being radiated on Channel D. In addition, the impedance of the Bob Smith termination is 75  $\Omega$  Channel A, B, C and 300  $\Omega$  Channel D, whereas the PHY input impedance is 100  $\Omega$ .

**Figure 13-1. Basic MDI Placement Guidelines**

The X550, referred to as a LAN silicon in [Figure 13-2](#) and [Figure 13-3](#), must be at least 1.5 inches from the I/O back panel. To help reduce EMI, the following recommendations should be followed:

- Minimize the length of the MDI interface.
- Place the MDI traces no closer than 0.5 inch (1.3 cm) from the board edge.

**Figure 13-2. Effect of Device Placed Less Than One Inch from the RJ-45 Connector**

The associated grounding scheme (blue) with the front-end of the chip is shown in the microstrip traces between the transformer and the RJ-45 (see [Figure 13-3](#)).

**Figure 13-3. Transformer Bypass Components**

**Figure 13-4. MDI Grounds**

From these figures (Figure 13-3 and Figure 13-4), the following should be noted:

- The ground is split underneath the magnetics, with the chassis ground being present under the front-end (Figure 13-3), and the circuit ground under the X550 side of the magnetics. Thus, the MDI traces on the line side are referenced to chassis ground.
- The magnetic module is used with the common mode choke facing the X550. This enables a Bob Smith termination to be implemented from the line side transformer center taps to chassis ground.
- Bob Smith termination and the shield of the RJ-45 jack are both connected to chassis ground, which are the two large circular metalizations in the MDI (see Figure 13-4).
- The resistors in the Bob Smith termination are required to be 0805s to handle the cable discharge voltages.
- Similarly, the magnetics should be placed as close as possible to the RJ-45 jack.
- In Figure 13-3, the Hi-POT clearance for cable discharge is shown and designed with  $\geq 80$  mils of clearance from the ground. Note that the breakdown voltage in FR-4 is lowest in the x-y axes planar to the PCB and highest in the z-axis between layers.

### 13.2.5.2 Integrated Magnetics

The 5th MDI channel previously described in discrete magnetics implementation is still realized when using integrated magnetics, with some notable exceptions (see Figure 13-5). The required termination, reference ground-plane division, and 5th channel wiring to the 4th channel center-tap occur within the integrated magnetics module. The guidance on MDI trace implementation between the X550 and the integrated module remains the same as with discrete magnetics, including length requirements and target impedance.

**Figure 13-5. Basic MDI Placement Guidelines**

**Note:** The RJ-45 jack and 10GBase-T Magnetics (red outline) are included in the integrated magnetics module.

The differences between the discrete and integrated magnetics implementations are as follows:

- The ground split that occurs underneath discrete magnetics modules is performed internally when using integrated magnetics. As a result, this ground split does not need to be addressed.
- The required Bob Smith termination is implemented internally when using integrated magnetics.

### 13.2.5.3 MDI Differential Pair Trace Routing for LAN Design

Trace routing considerations are important to minimize the effects of crosstalk and propagation delays on sections of the board where high-speed signals exist. Signal traces should be kept as short as possible to decrease interference from other signals, including those propagated through power and ground planes.

### 13.2.5.4 Signal Trace Geometry

One of the key factors in controlling trace EMI radiation are the trace length and the ratio of trace-width to trace-height above the reference plane. To minimize trace inductance, high-speed signals and signal layers that are close to a reference or power plane should be as short and wide as practical. Ideally, the trace-width to trace-height above the ground plane ratio is between 1:1 and 3:1. To maintain trace impedance, the width of the trace should be modified when changing from one board layer to another if the two layers are not equidistant from the neighboring planes.

Each pair of signals should target a differential impedance of  $100\ \Omega \pm 15\%$ .

A set of trace length calculation tools are made available from Intel to aid with MDI topology design. Contact your Intel representative for tool availability.

When designing a board layout, the automatic router feature of the CAD tool must not route the differential pairs without intervention. In most cases, the differential pairs require manual routing.

**Note:** Measuring trace impedance for layout designs targeting 100  $\Omega$  often results in lower actual impedance due to over-etching. Designers should verify actual trace impedance and adjust the layout accordingly. If the actual impedance is consistently low, a target of 105  $\Omega$  to 110  $\Omega$  should compensate for over-etching.

#### 13.2.5.4.1 Matching Traces within a Pair (P and N)

P and N for each MDI pair should be matched to within 5 mils on the PCB to prevent common-to-differential and differential-to-common conversion due to the length mismatch.

If in-pair length matching is not possible using bends or small loops, serpentine routing (zig-zag of a shorter trace) is acceptable if only one to three meanders are routed within 200 mils of the source of the skew or the end(s) of any otherwise unmatched lengths of a differential trace segment. For example, near device pins and/or at or near the connector pins and possibly at differential signal vias. Refer to the Intel® Ethernet Controller X550 Checklists for more details.

**Table 13-1. MDI Routing Summary**

| Parameter                                                             | Main Route Guidelines                   | Breakout Guidelines <sup>1</sup> | Notes          |
|-----------------------------------------------------------------------|-----------------------------------------|----------------------------------|----------------|
| Signal group                                                          | MDI_P[3:0]<br>MDI_N[3:0]                |                                  |                |
| Microstrip*/Stripline* uncoupled single-ended impedance specification | 50 $\Omega$ $\pm$ 10%                   |                                  |                |
| Microstrip/Stripline uncoupled differential impedance specification   | 100 $\Omega$ $\pm$ 15%                  |                                  | <sup>2,3</sup> |
| Microstrip nominal trace width                                        | Design dependent                        | Design dependent                 |                |
| Microstrip nominal trace space                                        | Design dependent                        | Design dependent                 | <sup>3</sup>   |
| Microstrip/Stripline trace length                                     | < 8 inches                              |                                  | Table 13-2     |
| Microstrip/Stripline pair-to-pair space (edge-to-edge)                | $\geq$ 7 times the dielectric thickness |                                  |                |
| Microstrip/Stripline bus-to-bus spacing                               | $\geq$ 7 times the dielectric thickness |                                  |                |
| Matching traces within a pair (P and N)                               | < 5 mils                                |                                  |                |
| Keep pair-to-pair length differences                                  | < 2 inches                              |                                  |                |

1. Pair-to-pair spacing  $\geq$  7 times the dielectric thickness for a maximum distance of 500 mils from the pin. The phase tolerance between MDI\_P and MDI\_N is <5mils.
2. Board designers should ideally target 100  $\Omega$   $\pm$ 10%. If it's not feasible (due to board stackup) it is recommended that board designers use a 95  $\Omega$   $\pm$ 10% target differential impedance for MDI with the expectation that the center of the impedance is always targeted at 95  $\Omega$ . The  $\pm$ 10% tolerance is provided to allow for board manufacturing process variations and not lower target impedances. The minimum value of impedance cannot be lower than 90  $\Omega$ .
3. Simulation shows 80 $\Omega$  differential trace impedances degrade MDI return loss measurements by approximately 1 dB from that of 90  $\Omega$ .

**Table 13-2. Maximum Trace Lengths Based on Trace Geometry and Board Stackup**

| Dielectric Thickness (mils) | Dielectric Constant (DK) at 1 MHz | Width / Space / Width (mils) | Pair-to-Pair Space (mils) | Nominal Impedance ( $\Omega$ ) | Impedance Tolerance (+/-%) | Maximum Trace Length (inches) <sup>1</sup> |
|-----------------------------|-----------------------------------|------------------------------|---------------------------|--------------------------------|----------------------------|--------------------------------------------|
| 2.7                         | 4.05                              | 4 / 10 / 4                   | 19                        | 95 <sup>2</sup>                | 17 <sup>2</sup>            | 3.5                                        |
| 2.7                         | 4.05                              | 4 / 10 / 4                   | 19                        | 95 <sup>2</sup>                | 15 <sup>2</sup>            | 4                                          |
| 2.7                         | 4.05                              | 4 / 10 / 4                   | 19                        | 95                             | 10                         | 5                                          |
| 3.3                         | 4.1                               | 4.2 / 9 / 4.2                | 23                        | 100 <sup>2</sup>               | 17 <sup>2</sup>            | 4                                          |
| 3.3                         | 4.1                               | 4.2 / 9 / 4.2                | 23                        | 100                            | 15                         | 4.6                                        |
| 3.3                         | 4.1                               | 4.2 / 9 / 4.2                | 23                        | 100                            | 10                         | 6                                          |
| 4                           | 4.2                               | 5 / 9 / 5                    | 28                        | 100 <sup>2</sup>               | 17 <sup>2</sup>            | 4.5                                        |
| 4                           | 4.2                               | 5 / 9 / 5                    | 28                        | 100                            | 15                         | 5.3                                        |
| 4                           | 4.2                               | 5 / 9 / 5                    | 28                        | 100                            | 10                         | 7                                          |

1. Longer MDI trace lengths can be achievable, but might make it more difficult to achieve IEEE conformance. Simulations have shown deviations are possible if traces are kept short. Longer traces are possible; use cost considerations and stackup tolerance for differential pairs to determine length requirements.
2. Deviations from 100  $\Omega$  nominal and/or tolerances greater than 15% decrease the maximum length for IEEE conformance.

**Note:** Use the MDI Differential Trace Calculator to determine the maximum MDI trace length for your trace geometry and board stackup. Contact your Intel representative for access.

The following factors can limit the maximum MDI differential trace lengths for IEEE conformance:

- Dielectric thickness
- Dielectric constant
- Nominal differential trace impedance
- Trace impedance tolerance
- Copper trace losses
- Additional devices, such as switches, in the MDI path might impact IEEE conformance.

Board geometry should also be factored in when setting trace length.

### 13.2.5.5 Ground Planes Under a Magnetics Module

The magnetics module chassis or output ground (secondary side of transformer) should be separated from the digital or input ground (primary side) by a physical separation of 80 mils minimum. Splitting the ground planes beneath the transformer minimizes noise coupling between the primary and secondary sides of the transformer and between the adjacent coils in the magnetics. This arrangement also improves the common mode choke functionality of magnetics module.

Integrated magnetics perform this ground plane separation internally. As a result, the ground plane split previously described is not needed when using integrated magnetics.

## 13.2.6 PHY MDI Lane Swap Configuration

The X550 provides flexible MDI LAN swaps for MDI board routing (see Figure 13-6) via an NVM setting.

- Default configuration - 0, 1, 2, 3 <-> A, B, C, D
- MDI swap configuration - 3, 2, 1, 0 <-> A, B, C, D
- 5th channel swap not supported (MDIx\_4\_P and MDIx\_4\_N)

**Figure 13-6. MDI Lane Swap Configuration**

## 13.2.7 Center Tap Connection Via Capacitors to Ground

The X550 has a voltage-mode driver. When using it in 10GBASE-T applications, it is required that a center tap be de-coupled to ground. When using an integrated magnetic, a 0.1  $\mu\text{F}$  capacitor should be connected from each center tap pin to ground. Similarly, when using a discrete magnetic, add a 0.1  $\mu\text{F}$  capacitor to each center tap pin for a total of five capacitors, as previously described.

## 13.3 Connecting the Power Supply Delivery Network

For the X550, it is necessary to provide an adequate power supply delivery network such that the performance of the device meets expected performance requirements. To achieve this goal, both high speed and bulk decoupling capacitor networks are required in the design to ensure that frequency performance of the power supply delivery network is flat across the frequency spectrum. For details on how many high frequency and bulk decoupling capacitors are necessary to achieve this requirement along with the associated values of these capacitors, refer to the *X550 10GBASE-T Dual Port Ethernet Controller Reference Design* schematics.

To further ensure that these specific high frequency and bulk decoupling capacitors are placed in locations around and under the X550, [Figure 13-7](#) breaks out the five required voltage supplies and color codes them according to power supply domain as a potential reference placement. Around the outside of the X550, highlighted bulk decoupling capacitors can be seen and because of their capacitance value and relative size, should be placed outside the BGA landing pattern. These decoupling capacitors still provide efficient bulk decoupling performance, as their capacitance value, along with the inductance of copper connecting them, still perform optimally.

**Figure 13-7. Power Supply Delivery Network**

Within the BGA landing pattern it is recommended that the high speed decoupling capacitors be placed directly below the X550 on the secondary side of the PCB to ensure a low inductance path connection. For each power supply domain, the associated high speed decoupling capacitors should be placed in a way to provide coverage for all BGA locations. It is not Intel's recommendation that each power supply domain ball have a unique high-speed decoupling capacitor, but rather that the high speed decoupling capacitors required from the reference schematic for each power supply domain provide consistent coverage across the targeted BGA connection locations.

## 13.4 Connecting the Flash Interface

### 13.4.1 Connecting the Flash

The X550 provides support for a Serial Peripheral Interface (SPI) Flash device that is made accessible to the system through the following:

- Flash Base Address register (PCIe Control register at offset 0x14 or 0x18).
- An address range of the IOADDR register, defined by the I/O Base Address register (PCIe Control register at offset 0x18 or 0x20).
- Expansion ROM Base Address register (PCIe Control register at offset 0x30)

### 13.4.2 Supported Flash Devices

The X550 uses a SPI Flash. Several words of the Flash are accessed automatically by the X550 after reset to provide pre-boot configuration data before it is accessed by host software. The remainder of the Flash space is available to software for storing the MAC address, serial numbers, and additional information. For a complete description of the content stored in the Flash refer to [Section 6.0](#).

Supported Op Code:

- Write Enable (06)
- Read Status Register (05)
- Write Status Register (01)
- Read Data (03)
- Byte/Page Program (02) (program 1 to 256 data bytes)
- 4 KB Sector Erase (20)
- Chip Erase (C7)

**Note:** For the Write Status register op code, the written data is 0x00 (to cancel the default protection).

The X550 contains a 3.3V Flash I/O.

## 13.5 Connecting Manageability Interfaces

SMBus and NC-SI are optional interfaces for pass-through and/or configuration traffic between the MC and the X550. For a description of the operation mode of these interfaces, refer to [Section 7.0](#) and [Section 12.0](#).

### 13.5.1 Connecting the SMBus Interface

To connect the SMBus interface to the chipset or the MC; connect the SMBD, SMBCLK and SMBALRT\_N signals to the corresponding pins of the chipset/MC. These pins require pull-up resistors to the 3.3V supply rail.

**Note:** If the interface is not used, the previously mentioned pull-up resistors on the SMBD, SMBCLK and SMBALRT\_N signals still have to be in place.

It is recommended that the SMBus be connected to the chipset or MC for the Flash recovery solution. If the connection is to a MC, it is able to send the Flash release command.

### 13.5.2 Connecting the NC-SI Interface

The NC-SI interface is a connection to an external MC. It operates as a single interface with an external MC, where all traffic (other than header redirection) between the X550 and the MC flows through the interface.

#### 13.5.2.1 External MC

The external MC is required to meet the electrical specifications called out in the NC-SI specification.

#### 13.5.2.2 Single and Multi-Drop Applications

[Figure 13-8](#) shows the connectivity requirements and provides information about a single-drop application. This configuration only has a single package connected to the MC. The X550 does support a multi-drop NC-SI configuration architecture, including hardware arbitration support from the MC. refer to the NC-SI specification for requirements for multi-drop applications.

Figure 13-8. External MC Connections with NC-SI and SMBus

### 13.5.2.3 Pull-Ups and Pull-Downs

Depending on whether or not the NC-SI interface is used, different pull-up and pull-down resistors are required. Figure 13-8 shows the connectivity requirements necessary for interfacing a NC-SI compliant MC.

Figure 13-9. NC-SI Connections to an External MC

## 13.5.3 Layout Requirements

### 13.5.3.1 Board Impedance

The NC-SI manageability interface is a single ended signaling environment. It is recommended that a target board and trace impedance of 50 plus 20% and minus 10%. This ensures optimal signal integrity.

### 13.5.3.2 Trace Length Restrictions

It is recommended that a trace length maximum value from a board placement and routing topology perspective of eight inches for direct connect applications. This ensures signal integrity and quality is preserved from a design perspective and that compliance is met for NC-SI electrical requirements.

**Figure 13-10. NC-SI Maximum Trace Length Requirement for Direct Connect Applications**

For multi-drop applications, a spacing recommendation of a maximum of four inches between the two packages connected to the same MC. This is done to keep the overall length between the MC and the X550 within specification. See [Figure 13-11](#)

**Figure 13-11. Spacing Recommendation for Multi-Drop Applications**

### 13.5.3.3 Special Delay Requirements

To ensure that the X550 is able to communicate with a specification-compliant MC, the following guidelines must be followed:

- Total skew from the clock source to all devices should be less than 1 ns (less than or equal to an approximate 5.5 inch trace length skew).
- Each inch of trace has about 160 ps to 180 ps of delay, depending on the effective dielectric constant.

## 13.6 Connecting the Software-Definable Pins (SDPs)

The X550 has four SDPs per port that can be used for miscellaneous hardware or software-controllable purposes. These pins and their function are bound to a specific LAN device. The pins can each be individually configured to act as either input or output pins via Flash. The initial value in case of an output can also be configured in the same way. However, the X550 default for any of these pins is to be configured as outputs.

To avoid signal contention, all four pins (per port) are set as input pins until the Flash configuration has been loaded.

Choose the correct SDPs for specific applications. All pins are tri-state buffers. Consider that four of these pins (SDPx\_0 – SDPx\_3) can be used to support IEEE1588 auxiliary devices, input for external interrupts, indication for thermal-sensor event or as general purpose interrupt (GPI) inputs. To act as GPI pins, the desired pins must be configured as inputs. A separate GPI interrupt-detection enable is then used to enable rising-edge detection of the input pin (rising-edge detection occurs by comparing values sampled at 62.5 MHz, as opposed to an edge-detection circuit). When detected, a corresponding GPI interrupt is indicated in the Interrupt Cause register.

When connecting the SDPs to different digital signals please keep in mind that these are 3.3V signals and use level shifting if necessary.

The use, direction, and values of SDPs are controlled and accessed using fields in the Extended SDP Control (ESDP) and Extended OD SDP Control (EODSDP) registers.

## 13.7 Connecting the Light Emitting Diodes (LEDs)

The X550 provides four programmable high-current sink (active high) outputs per port to directly drive LEDs for link activity and speed indication. Each LAN device provides an independent set of LED outputs; these pins and their function are bound to a specific LAN device. Each of the four LED outputs can be individually configured to select the particular event, state, or activity, which is indicated on that output. In addition, each LED can be individually configured for output polarity, as well as for blinking versus non-blinking (steady-state) indication.

The LED ports are fully programmable through the Flash interface (LEDCTL register). In addition, the hardware-default configuration for all LED outputs can be specified via a Flash field, thus supporting LED displays configurable to a particular OEM preference.

Provide separate current limiting resistors for each LED connected.

Since the LEDs are likely to be placed close to the board edge and to external interconnect, take care to route the LED traces away from potential sources of EMI noise. In some cases, it might be desirable to attach filter capacitors.

## 13.8 Connecting Miscellaneous Signals

### 13.8.1 LAN Disable

The X550 has two signals that can be used for disabling Ethernet functions from system BIOS. LAN0\_DIS\_N and LAN1\_DIS\_N are the separated port disable signals. Each signal can be driven from a system output port. Choose outputs from devices that retain their values during reset. For example, some PCH GPIO outputs transition high during reset. It is important not to use these signals to drive LAN0\_DIS\_N or LAN1\_DIS\_N because these inputs are latched upon the rising edge of PE\_RST\_N or an in-band reset end.

A LAN port can also be disabled through Flash settings. See [Section 4.4](#) for details. Note that setting the Flash LAN\_PCI\_DIS bit does not bring the PHY into power down.

**Table 13-3. PCI Functions Mapping (Legacy Mode)**

| PCI Function #                  | LAN Function Select                                             | Function 0 | Function 1 |
|---------------------------------|-----------------------------------------------------------------|------------|------------|
| Both LAN functions are enabled  | 0                                                               | LAN 0      | LAN 1      |
|                                 | 1                                                               | LAN 1      | LAN 0      |
| LAN 0 is disabled               | x                                                               | LAN 1      | Disable    |
| LAN 1 is disabled               | x                                                               | LAN 0      | Disable    |
| Both LAN functions are disabled | Both PCI functions are disabled. The X550 is in low power mode. |            |            |

**Table 13-4. PCI Functions Mapping (Dummy Function Mode)**

| PCI Function #                  | LAN Function Select                                           | Function 0 | Function 1 |
|---------------------------------|---------------------------------------------------------------|------------|------------|
| Both LAN functions are enabled  | 0                                                             | LAN 0      | LAN 1      |
|                                 | 1                                                             | LAN 1      | LAN 0      |
| LAN 0 is disabled               | 0                                                             | Dummy      | LAN 1      |
|                                 | 1                                                             | LAN 1      | Disable    |
| LAN 1 is disabled               | 0                                                             | LAN 0      | Disable    |
|                                 | 1                                                             | Dummy      | LAN 0      |
| Both LAN functions are disabled | Both PCI functions are disabled. Device is in low power mode. |            |            |

When both LAN ports are disabled following a power on reset / LAN\_PWR\_GOOD / PE\_RST\_N / in-band reset, the LAN\_DIS\_N signals should be tied statically to low. At this state, the X550 is disabled, LAN ports are powered down, all internal clocks are shut and the PCIe connection is powered down (similar to L2 state).

## 13.8.2 BIOS Handling of Device Disable

Assume that in the following power up sequence the LANx\_DIS\_N signals are driven high (or is already disabled):

1. PCIe link is established following the PE\_RST\_N.
2. BIOS recognizes that the X550 should be disabled.
3. BIOS drives the LANx\_DIS\_N signals to the low level.
4. BIOS issues PE\_RST\_N or an in-band PCIe reset.
5. As a result, the X550 samples the LANx\_DIS\_N signals and enters the desired device-disable mode.
6. Re-enable could be done by driving high one of the LANx\_DIS\_N signals and then issuing a PE\_RST\_N to restart the X550.

## 13.9 Connecting the JTAG Port

The X550 contains a test access port (3.3 V only) conforming to the IEEE 1149.1-2001 Edition (JTAG) specification. To use the test access port, connect these balls to pads accessible by specific test equipment.

For proper operation, a pull-down resistor should be connected to the JTCK and JRST\_N signals and pull up resistors to the JTDO, JTMS and JTDI signals.

A Boundary Scan Definition Language (BSDL) file describing the X550 is available for use in specific test environments.

## 13.10 Power On Reset (POR)

After power is applied, the X550 must be reset. There are two ways to do this:

1. Using the internal Power on Reset (POR) circuit with external LAN\_PWR\_GOOD signal pulled up.
2. Using the internal POR circuit with the external reset as LAN\_PWR\_GOOD signal generated by the system.

The power supply sequencing timing requirement between the 3.3V and 2.1V, 1.2V, and 0.83V power rails has to be met (see [Section 12.3.8](#)).

There are two options for implementing POR:

1. Internal POR (recommended as default).
  - a. BYPASS\_POR signal (pull down).
  - b. LAN\_PWR\_GOOD signal (pull up).
2. External reset with LAN\_PWR\_GOOD signal:
  - a. BYPASS\_POR signal (pull down).
  - b. LAN\_PWR\_GOOD signal generated by the system following device power-up timing.

## 13.11 Crystal Design Considerations

This section provides information regarding crystals for use with the X550.

All designs require an external clock. The only option for this clock source is a 50 MHz external crystal. The X550 uses the crystal to generate clocks for the high speed interfaces.

The chosen crystal vendor should be consulted early in the design cycle. Crystal manufacturers familiar with networking equipment clock requirements might provide assistance in selecting an optimum, low-cost solution.

### 13.11.1 Quartz Crystal

Quartz crystals are the mainstay of frequency components due to low cost and ease of implementation. They are available from numerous vendors in many package types with various specification options.

### 13.11.2 Vibrational Mode

Crystals are available in both fundamental and third overtone. Unless there is a special need for third overtone, use fundamental mode crystals. At any operating frequency, third overtone crystals are thicker and more rugged than fundamental mode crystals. Third overtone crystals are more suitable for use in military or harsh industrial environments. Third overtone crystals require a trap circuit (extra capacitor and inductor) in the load circuitry to suppress fundamental mode oscillation as the circuit powers up. Selecting values for these components is beyond the scope of this document.

### 13.11.3 Frequency Tolerance

The frequency tolerance for an Ethernet Platform LAN Connect is dictated by the IEEE 802.3 specification as  $\pm 50$  parts per million (ppm). This measurement is referenced to a standard temperature of 25° C. It is recommended that a frequency tolerance of  $\pm 10$  ppm be used.

### 13.11.4 Temperature Stability and Environmental Requirements

Temperature stability is a standard measure of how the oscillation frequency varies over the full operational temperature range (and beyond). Several optional temperature ranges are currently available, including -10 °C to +70 °C for industrial environments. Some vendors separate operating temperatures from temperature stability. Manufacturers can also list temperature stability as 50 ppm in their data sheets.

**Note:** Crystals also carry other specifications for storage temperature, shock resistance, and reflow solder conditions. Crystal vendors should be consulted early in the design cycle to discuss the application and its environmental requirements.

## 13.11.5 Calibration Mode

The terms series-resonant and parallel-resonant are used to describe crystal oscillator circuits. Specifying parallel mode is critical to determining how the crystal frequency is calibrated at the factory. A crystal specified and tested as series resonant oscillates without problem in a parallel-resonant circuit, but the frequency is higher than nominal by several hundred parts per million. The purpose of adding load capacitors to a crystal oscillator circuit is to establish resonance at a frequency higher than the crystal's inherent series resonant frequency.

## 13.11.6 Reference Crystal Circuit

Figure 13-12 illustrates a simplified schematic of the internal oscillator circuit. Pin X1 and X2 refers to XTAL1 and XTAL2 in the X550, respectively. The crystal and the capacitors form a feedback element for the internal inverting amplifier. This combination is called parallel-resonant, because it has positive reactance at the selected frequency. In other words, the crystal behaves like an inductor in a parallel LC circuit. Oscillators with piezoelectric feedback elements are also known as Pierce oscillators.

Figure 13-12. Oscillator Circuit

## 13.11.7 Crystal Load Capacitance

The formula for crystal load capacitance is as follows:

$$C_L = \frac{(C1 \cdot C2)}{(C1 + C2)} + C_{stray}$$

where  $C1 = C2 = 18 \text{ pF}$  and  $C_{stray}$  = allowance for additional capacitance in pads, traces and the chip carrier within the Ethernet device package. An allowance of 3 pF to 7 pF accounts for lumped stray capacitance. The calculated load capacitance is 16 pF with an estimated stray capacitance of about 5 pF. Individual stray capacitance components can be estimated and added. For example, surface mount pads for the load capacitors add approximately 2.5 pF in parallel to each capacitor. This technique is especially useful if Y1, C1 and C2 must be placed farther than approximately one-half (0.5) inch from the device. Thin circuit boards generally have higher stray capacitance than thick circuit boards. Oscillator frequency should be measured with a precision frequency counter where possible. The load specification or values of C1 and C2 should be fine-tuned for the design. As the actual capacitance load increases, the oscillator frequency decreases.

**Note:** C1 and C2 can vary by as much as 5% (approximately 1 pF) from their nominal values.

### 13.11.8 Shunt Capacitance

The shunt capacitance parameter is relatively unimportant compared to load capacitance. Shunt capacitance represents the effect of the crystal's mechanical holder and contacts. The shunt capacitance should equal a maximum of 5 pF.

### 13.11.9 Equivalent Series Resistance (ESR)

ESR is the actual component of the crystal's impedance at the calibration frequency, which the inverting amplifier's loop gain must overcome. ESR varies inversely with frequency for a given crystal family. The lower the ESR, the faster the crystal starts up. Use crystals with an ESR value of 50  $\Omega$  or better.

### 13.11.10 Driver Level

Drive level refers to power dissipation in use. The allowable drive level for a Surface Mounted Technology (SMT) crystal is less than its through-hole counterpart, because surface mount crystals are typically made from narrow, rectangular AT strips, rather than circular AT quartz blanks. Some crystal data sheets list crystals with a maximum drive level of 1 mW. However, Intel Ethernet controllers drive crystals to a level less than the suggested 0.3 mW value. This parameter does not have much value for on-chip oscillator use.

### 13.11.11 Aging

Aging is a permanent change in frequency (and resistance) occurring over time. This parameter is most important in its first year because new crystals age faster than old crystals. Use crystals with a maximum of  $\pm 5$  ppm per year aging.

### 13.11.12 Reference Crystal

The normal tolerances of the discrete crystal components can contribute to small frequency offsets with respect to the target center frequency. To minimize the risk of tolerance-caused frequency offsets causing a small percentage of production line units to be outside of the acceptable frequency range, it is important to account for those shifts while empirically determining the proper values for the discrete loading capacitors, C1 and C2. Even with a perfect support circuit, most crystals oscillate slightly higher or slightly lower than the exact center of the target frequency. Therefore, frequency measurements (which determine the correct value for C1 and C2) should be performed with an ideal reference crystal. When the capacitive load is exactly equal to the crystal's load rating, an ideal reference crystal is perfectly centered at the desired target frequency.

### 13.11.13 Reference Crystal Selection

There are several methods available for choosing the appropriate reference crystal. These are listed below.

- If a Saunders and Associates (S&A) crystal network analyzer is available, discrete crystal components can be tested until one is found with zero or nearly zero ppm deviation (with the appropriate capacitive load). A crystal with zero or near zero ppm deviation is a good reference crystal to use in subsequent frequency tests to determine the best values for C1 and C2.
- If a crystal analyzer is not available, the selection of a reference crystal can be done by measuring a statistically valid sample population of crystals, which has units from multiple lots and approved vendors. The crystal, which has an oscillation frequency closest to the center of the distribution, should be the reference crystal used during testing to determine the best values for C1 and C2.
- It might also be possible to ask the approved crystal vendors or manufacturers to provide a reference crystal with zero or nearly zero deviation from the specified frequency when it has the specified CLoad capacitance.

When choosing a crystal, keep in mind that to comply with IEEE specifications for 100/ 1000/10GBase-T Ethernet LAN, the transmitter reference frequency must be precise within  $\pm 50$  ppm. Intel® recommends using a transmitter reference frequency that is accurate to within  $\pm 10$  ppm to account for variations in crystal accuracy due to crystal manufacturing tolerance.

### 13.11.14 Circuit Board

Since dielectric layers of the circuit board are allowed some reasonable variation in thickness, stray capacitance from the printed board (to the crystal circuit) also vary. If the thickness tolerance for the outer layers of dielectric are controlled within  $\pm 17$  percent of nominal, the circuit board should not cause more than  $\pm 2$  pF variation to the stray capacitance at the crystal. When tuning crystal frequency, it is recommended that at least three circuit boards are tested for frequency. These boards should be from different production lots of bare circuit boards. Alternatively, a larger sample population of circuit boards can be used. A larger population increases the probability of obtaining the full range of possible variations in dielectric thickness and the full range of variation in stray capacitance. Next, the exact same crystal and discrete load capacitors (C1 and C2) must be soldered onto each board and the LAN reference frequency should be measured on each circuit board. The circuit board, which has a LAN reference frequency closest to the center of the frequency distribution, should be used while performing the frequency measurements to select the appropriate value for C1 and C2.

### 13.11.15 Temperature Changes

Temperature changes can cause crystal frequency to shift. Frequency measurements should be done in the final system chassis across the system's rated operating temperature range.

## 13.12 PCB Guidelines

This section describes the general PCB design guidance targeted as supplementary information in addition to the specific requirements and recommendations for individual interfaces. For items not directly covered in the specific interface sections, these guidance recommendations apply to the design.

### 13.12.1 Board Stack-Up Example

PCBs for these designs typically have six, eight, or more layers. Although the X550 does not dictate stackup, the following examples show typical stack-up options.

Microstrip Example:

- Layer 1 is a signal layer.
- Layer 2 is a ground layer.
- Layer 3 is used for power planes.
- Layer 4 is a signal layer. Careful routing is necessary to prevent crosstalk with layer 5.
- Layer 5 is a signal layer. Careful routing is necessary to prevent crosstalk with layer 4.
- Layer 6 is used for power planes.
- Layer 7 is a signal ground layer.
- Layer 8 is a signal layer.

**Note:** Layers 4 and 5 should be used mostly for low-speed signals because they are referenced to potentially noisy power planes that might also be slotted.

Stripline Example:

- Layer 1 is a signal layer.
- Layer 2 is a ground layer.
- Layer 3 is a signal layer.
- Layer 4 is used for power planes.
- Layer 5 is used for power planes.
- Layer 6 is a signal layer.
- Layer 7 is a signal ground layer.
- Layer 8 is a signal layer.

**Note:** To avoid the effect of the potentially noisy power planes on the high-speed signals, use offset stripline topology. The dielectric distance between the power plane and signal layer should be three times the distance between ground and signal layer.

This board stack-up configuration can be adjusted to conform to company-specific design rules.

## 13.12.2 Customer Reference Board Stack-Up Example

| Layer Name | Plane Description      | Layer Thickness (mil) | Copper Weight (oz) | Dielectric eR |
|------------|------------------------|-----------------------|--------------------|---------------|
|            | solder mask            | 0.5                   |                    | 3.8           |
| Signal 1   | SIGNAL                 | 1.9                   | 1.5                |               |
|            | 1080-prepreg           | 2.7                   |                    | 4.0           |
| Plane 2    | GND DDR PWR GND        | 1.3                   | 1.0                |               |
|            | core                   | 4.0                   |                    | 4.1           |
| Signal 3   | SIGNAL                 | 1.3                   | 1.0                |               |
|            | prepreg                | 12.0                  |                    | 4.0           |
| Plane 4    | POWER (Vddq, GND, Vtt) | 2.6                   | 2.0                |               |
|            | core                   | 4.0                   |                    | 4.1           |
| Plane 5    | POWER (12V input)      | 2.6                   | 2.0                |               |
|            | prepreg                | 6.0                   |                    | 4.0           |
| Plane 6    | POWER (PLL, VSA,       | 2.6                   | 2.0                |               |
|            | core                   | 4.0                   |                    | 4.1           |
| Plane 7    | GND                    | 2.6                   | 2.0                |               |
|            | prepreg                | 12.0                  |                    | 4.0           |
| Signal 8   | SIGNAL                 | 1.3                   | 1.0                |               |
|            | core                   | 4.0                   |                    | 4.1           |
| Plane 9    | GND DDR PWR GND        | 1.3                   | 1.0                |               |
|            | 1080-prepreg           | 2.7                   |                    | 4.0           |
| Signal 10  | SIGNAL                 | 1.9                   | 1.5                |               |
|            | solder mask            | 0.5                   |                    | 3.8           |
|            |                        | 71.8                  |                    |               |

 EACH CORE LAYER MUST HAVE CORE NOMINAL WITHOUT CU - .010 , .0102 , .0052 ETC  
 CORE TOLERANCE IS NOT CALCULATED AND NEEDS TO BE CONSIDERED

## 13.12.4 Via Usage

Use vias to optimize signal integrity. Figure 13-13 shows correct via usage. Figure 13-14 shows the type of topology that should be avoided.

**Figure 13-13. Correct Via Usage**

**Figure 13-14. Incorrect Via Usage**

Any via stubs on the MDI differential signal traces must be less than 35 mils in length. Keeping MDI signal via stubs less than or equal to 20 mils is preferable.

Place ground vias adjacent to signal vias used for the MDI interface. DO NOT embed vias between the high-speed signals, but place them adjacent to the signal vias. This helps to create a better ground path for the return current of the AC signals, which also helps address impedance mismatches and EMC performance.

It is recommend that, in the breakout region between the via and the capacitor pad, target a Z0 for the via to capacitor trace equal to 50  $\Omega$ . This minimizes impedance imbalance.

**Figure 13-15. Incorrect Via Usage for Differential Pair**

## 13.12.5 Reference Planes

Do not cross plane splits with the MDI high-speed differential signals. This causes impedance mismatches and negatively affects the return current paths for the board design and layout. See [Figure 13-16](#).

**Figure 13-16. Improper Differential Signal Routing - Plane Split**

Traces should not cross power or ground plane splits if at all possible. Traces should stay seven times the dielectric height away from plane splits or voids. If traces must cross splits, capacitive coupling should be added to stitch the two planes together to provide a better AC return path for the high-speed signals. To be effective, the capacitors should have low ESR and low equivalent series inductance.

**Note:** Even with plane split stitching capacitors, crossing plane splits is extremely high risk for 10GBASE-T designs.

**Figure 13-17. Differential Signal Routing - Plane split and Void Proximity**

It is recommended that the MDI signals stay at least seven times the dielectric height away from any power or ground plane split. This improves impedance balance and return current paths.

If a high-speed signal needs to reference a power plane, ensure that the height of the secondary (power) reference plane is at least 3 x the height of the primary (ground) reference plane.

### 13.12.6 Reducing Circuit Inductance

Traces should be routed over a continuous reference plane with no interruptions. If there are vacant areas on a reference or power plane, the signal conductors should not cross the vacant area. Routing over a void in the reference plane causes impedance mismatches and usually increases radiated noise levels. Noisy logic grounds should NOT be located near or under high-speed signals or near sensitive analog pin regions of the LAN silicon. If a noisy ground area must be near these sensitive signals or IC pins, ensure sufficient decoupling and bulk capacitance in these areas. Noisy logic and switching power supply grounds can sometimes affect sensitive DC subsystems such as analog to digital conversion, operational amplifiers, etc.

All ground vias should be connected to every ground plane; and similarly, every power via should be equally potential power planes. This helps reduce circuit inductance. Another recommendation is to physically locate grounds to minimize the loop area between a signal path and its return path. Rise and fall times should be as slow as possible while still meeting the relevant electrical requirements because signals with fast rise and fall times contain many high frequency harmonics, which can radiate significantly. The most sensitive signal returns closest to the chassis ground should be connected together. This results in a smaller loop area and reduces the likelihood of crosstalk. The effect of different configurations on the amount of crosstalk can be studied using electronics modeling and simulation software.

### 13.12.7 Signal Isolation

To maintain the best signal integrity, keep digital signals far away from the analog traces. A good rule to follow is no digital signal should be within 7x to 10x dielectric height of the differential pairs. If digital signals on other board layers cannot be separated by a ground plane, they should be routed at a right angle (90 degrees) to the differential signal traces. If there is another Ethernet controller on the board, take care to keep the differential pairs away from that circuit. The same thing applies to switching regulator traces.

Rules to follow for signal isolation:

- Separate and group signals by function on separate board layers if possible. Maintain a separation that is at least seven times the thinnest adjacent dielectric height between all differential pairs (Ethernet) and other nets, but group associated differential pairs together.
- Over the length of the trace run, each differential pair should be at least seven times the thinnest adjacent dielectric height away from any parallel signal traces.
- Physically group together all components associated with one clock trace to reduce trace length and radiation.
- Isolate other I/O signals from high-speed signals to minimize crosstalk. Crosstalk can increase radiated EMI and can also increase susceptibility to EMI from other signals.
- Avoid routing high-speed LAN traces near other high-frequency signals associated with a video controller, cache controller, processor, or other similar devices.

### 13.12.8 Traces for Decoupling Capacitors

Traces between decoupling and I/O filter capacitors should be as short and wide as practical. Long and thin traces are more inductive and reduce the intended effect of decoupling capacitors. Also, for similar reasons, traces to I/O signals and signal terminations should be as short as possible. Vias to the decoupling capacitors should be sufficiently large in diameter to decrease series inductance.

## 13.12.9 Power and Ground Planes

Good grounding requires minimizing inductance levels in the interconnections and keeping ground returns short, signal loop areas small, and locating decoupling capacitors at or near power inputs to bypass to the signal return. This significantly reduces EMI radiation.

These guidelines reduce circuit inductance in NICs and LOMs:

- Route traces over a continuous plane with no interruptions. Do not route over a split power or ground plane. If there are vacant areas on a ground or power plane, avoid routing signals over the vacant area. Routing signals over power or ground voids increases inductance and increases radiated EMI levels.
- Use distance and/or extra decoupling capacitors to separate noisy digital grounds from analog grounds to reduce coupling. Noisy digital grounds can affect sensitive DC subsystems.
- All ground vias should be connected to every ground plane, and every power via should be connected to all power planes at equal potential. This helps reduce circuit inductance.
- Physically locate grounds between a signal path and its return. This minimizes the loop area.
- Avoid fast rise/fall times as much as possible. Signals with fast rise and fall times contain many high frequency harmonics, which can radiate EMI.
- Do not route high-speed signals near switching regulator circuits.
- It's acceptable to put ground fill or thieving on the trace layers, but preferably not closer than 50 mils to the differential traces and the connector pins.
- If differential traces must be routed on another layer, the signal vias should carry the signal to the opposite side of the PCB (to be near the top of the PCB), AND if the high-speed signals are being routed between two connectors on the same board, before the signal traces reach the second connector, they must return to the original signal layer (before reaching the connector pin). This strategy keeps via stubs short without requiring back drilling.
- Each time differential traces make a layer transition (pass through a pair of signal vias), there must be at least one ground via located near each signal via. Two ground vias near each signal via is better. See [Figure 13-18](#) and [Figure 13-19](#).

**Figure 13-18. Return Path Vias for Differential Signals - Acceptable Example**

**Figure 13-19. Return Path Vias for Differential Signals - Optimal Example**

If the PCB fabrication process permits it, it's best to remove signal via pads on unconnected metal layers. See [Figure 13-20](#) and [Figure 13-21](#).

**Figure 13-20. Signal Vias: Improper Padstack Example**

**Figure 13-21. Signal Vias: Optimal Padstack**

On metal layers where signal vias need to have via pads, it is desirable to reduce capacitance between the signal vias and ground-plane layers. The anti-pad diameters should be up to 20 mils larger than the via pad diameters. See [Figure 13-22](#). Clearance between the pad and the surrounding metal should be  $\geq 10$  mils.

**Figure 13-22. Anti-Pad Geometry**

Each time differential signal vias pass through a plane layer, within each differential pair, the anti-pads should overlap. See [Figure 13-23](#), [Figure 13-24](#) and [Figure 13-25](#).

**Figure 13-23. Differential Signal Vias: Improper Anti-pad Geometry**

**Figure 13-24. Differential Signal Vias: Acceptable Example**

**Figure 13-25. Differential Signal Vias: Optimal Example**

### 13.12.10 Recommended Simulations

10GBASE-T signaling frequencies have frequency content in the range of 800 MHz and below so relatively short stubs, small discontinuities, and fairly small in-pair trace length differences can cause an undesirable increase in bit errors. Before ordering PCBs, verify that:

- Planned 10GBASE-T signal trace routing on the PCB complies with the interconnect characteristics recommended in IEEE 802.3an.
- With sufficient advance notice, Intel engineers can provide assistance under these conditions:
  - Trace routing should be optimized prior to the next steps – request a layout review (must be willing to provide board stack-up information and the MDI traces CAD artwork).
  - After MDI traces have been optimized, if the IEEE recommended electrical characteristics are still not being met, end-to-end MDI board channels S-parameter models should be extracted (preferably in Touchstone\* S4p format) for additional investigative simulations by Intel signal integrity engineers. Please request the required S-parameter frequency range, step size, etc., before extracting Touchstone S-parameter models.

## 13.13 Bill Of Material (BOM)

Table 13-5 lists the BOM materials for all X550 LAN on Motherboard (LOM) designs.

**Table 13-5. X550 LOMs**

| Component           | Manufacturer                                                                                     | Manufacturer Part Number                                                                                                                                                                                 | Quantity |

## 14.0 Thermal Design Recommendations

---

### 14.1 Introduction

This section can be used as an aid to designing a thermal solution for systems implementing the the X550.

**Note:** The information contained in this section is subject to change. Contact your Intel representative to ensure that you have the most current information.

Properly designed solutions provide adequate cooling to maintain the X550 case temperature ( $T_{case}$ ) at or below those listed in [Table 14-2](#). The device should function properly if case temperatures are kept at or below those presented. Ideally this is accomplished by providing a low local ambient temperature airflow, and creating a minimal thermal resistance to that local ambient temperature. Heat sinks and higher airflow might be required if case temperatures exceed those listed in [Table 14-2](#).

Information in this section includes:

- **Section 14.6, “Packaging Terminology”** — Provides definitions for terminology used in this section.
- **Section 14.7, “Thermal Specifications”** — Provides the X550 case temperature specifications and where to find power requirements. This sub-section also discusses thermal packaging techniques.
- **Section 14.8, “Thermal Attributes”** — Provides the X550 thermal characteristic data, package mechanical attributes, and package thermal characteristic data. Use this sub-section to determine your thermal solution requirements.
- **Section 14.9, “Thermal Enhancements”** — Discusses the use of heat sinks, heat sink attach methods, interfacing, and reliability.
- **Section 14.10, “Measurements for Thermal Specifications”** — Provides instructions for measuring the X550 case temperature with and without a heat sink.
- **Section 14.11, “Conclusion”** — Provides a summary.
- **Section 14.12, “Heat Sink and Attach Suppliers”** — Provides manufacturer contact information.
- **Section 14.13, “PCB Guidelines”** — Includes general PCB recommendations.

## 14.2 Intended Audience

The intended audience for this section is system design engineers using the X550. System designers are required to address component and system-level thermal challenges as the market continues to adopt products with higher-speeds and port densities. New designs might be required to provide better cooling solutions for silicon devices depending on the type of system and target operating environment.

## 14.3 Measuring Thermal Conditions

This section provides a method for determining the operating temperature of the X550 in a specific system based on case temperature. Case temperature is a function of the local ambient and internal temperatures of the component. This section specifies a maximum allowable  $T_{case}$  for the X550.

## 14.4 Thermal Considerations

In a system environment, the temperature of a component is a function of both the system and component thermal characteristics. System-level thermal constraints consist of the local ambient temperature at the component, the airflow over the component and surrounding board, and the physical constraints at, above, and surrounding the component that might limit the size of a thermal enhancement (heat sink).

The component's case/die temperature depends on:

- Component power dissipation
- Size
- Packaging materials (effective thermal conductivity)
- Type of interconnection to the substrate and motherboard
- Presence of a thermal cooling solution
- Power density of the substrate, nearby components, and motherboard

All of these parameters are pushed by the continued trend of technology to increase performance levels (higher operating speeds, MHz) and power density (more transistors). As operating frequencies increase and packaging size decreases, the power density increases and the thermal cooling solution space and airflow become more constrained. The result is an increased emphasis on system design to ensure that thermal design requirements are met for each component in the system.

## 14.5 Importance of Thermal Management

The thermal management objective is to ensure that all system component temperatures are maintained within functional limits. The functional temperature limit is the range in which the electrical circuits are expected to meet specified performance requirements. Operation outside the functional limit can degrade system performance, cause logic errors, or cause device and/or system damage. Temperatures exceeding the maximum operating limits can result in irreversible changes in the device operating characteristics. Also note that sustained operation at component maximum temperature limit might affect long-term device reliability (see [Section 12.2.2](#)).

## 14.6 Packaging Terminology

The following is a list of packaging terminology used in this section:

- **FCBGA Flip Chip Ball Grid Array** — A surface-mount package using a combination of flip chip and BGA structure whose PCB-interconnect method consists of Pb-free solder ball array on the interconnect side of the package. The die is flipped and connected to an organic build-up substrate with C4 bumps. An Integrated Heat Spreader (IHS) might be present for larger FCBGA packages for enhanced thermal performance (but IHS is not present for the X550).
- **Junction** — Refers to a P-N junction on the silicon. In this section, it is used as a temperature reference point (for example,  $\theta_{JA}$  refers to the junction-to-ambient thermal resistance).
- **Ambient** — Refers to local ambient temperature of the bulk air approaching the component. It can be measured by placing a thermocouple approximately 1 inch upstream from the component edge.
- **Lands** — The pads on the PCB to which BGA balls are soldered.
- **Printed Circuit Board** — PCB.
- **Printed Circuit Assembly (PCA)** — An assembled PCB.
- **Thermal Design Power (TDP)** — The estimated maximum possible/expected power generated in a component by a realistic application. Use the maximum power requirements listed in [Table 14-2](#).
- **Linear Feet Per Minute** — LFM (airflow).
- $\theta_{JA}$  (**Theta JA**) — Thermal resistance junction-to-ambient, °C/W.
- $\Psi_{JT}$  (**Psi JT**) — Junction-to-top (of package) thermal characterization parameter, °C/W.  $\Psi_{JT}$  does not represent thermal resistance, but instead is a characteristic parameter that can be used to convert between  $T_j$  and  $T_{case}$  when knowing the total TDP.  $\Psi_{JT}$  is easy to characterize in simulations or measurements, and is equal to  $T_j$  minus  $T_{case}$  divided by the total TDP. This parameter can vary by environment conditions like heat sink and airflow.

## 14.7 Thermal Specifications

**Important:** Information contained in this section is preliminary and subject to change without notice.

To ensure proper operation of the X550, the thermal solution must maintain a case temperature at or below the values listed in [Table 14-2](#). System-level or component-level thermal enhancements are required to dissipate the generated heat to ensure the case temperature never exceeds the maximum temperatures listed in [Table 14-2](#). [Table 14-1](#) lists the thermal performance parameters per JEDEC JESD51-2 standard. In [Table 14-1](#) the  $\theta_{JA}$  values should be used as reference only and can vary by system environment.  $\Psi_{JT}$  values also can vary by system environment, and are listed in [Table 14-1](#) as the maximum value for the X550 simulations.

Analysis indicates that real applications are unlikely to cause the X550 to be at  $T_{case-max}$  for sustained periods of time, given that  $T_{case}$  should reasonably be expected to be a distribution of temperatures. Sustained operation at  $T_{case-max}$  might affect long-term reliability of the X550 and the system. Also, sustained operation at  $T_{case-max}$  should be evaluated during the thermal design process and steps taken to further reduce the  $T_{case}$  temperature.

Good system airflow is critical to dissipate the highest possible thermal power. The size and number of fans, vents, and/or ducts as well as their placement in relation to components and airflow channels within the system determine airflow. Acoustic noise constraints might limit the size and types of fans, vents and ducts that can be used in a particular design.

To develop a reliable, cost-effective thermal solution, all of the system variables must be considered. Use system-level thermal characteristics and simulations to account for individual component thermal requirements.

**Table 14-1. Package Thermal Characteristics in Standard JEDEC Environment for Reference**

| Package                                  | $\theta_{JA}$ (°C/W) | $\Psi_{JT}$ (°C/W) |
|------------------------------------------|----------------------|--------------------|
| 25 mm FCBGA without IHS <sup>1</sup>     | 16.5 <sup>2</sup>    | N/A                |
| 25 mm FCBGA without IHS -HS <sup>3</sup> | 7.51 <sup>4</sup>    | 0.17 <sup>5</sup>  |
| 17 mm FCBGA without IHS <sup>1</sup>     | TBD                  | N/A                |
| 17 mm FCBGA without IHS -HS <sup>3</sup> | 7.51                 | 0.17               |

1. Integrated Heat Spreader. the X550 is bare die.
2. Integrated Circuit Thermal Measurement Method-Electrical Test Method EIA/JESD51-1, Integrated Circuits Thermal Test Method Environmental Conditions - Natural Convection (Still Air), No Heat sink attached EIA/JESD51-2.
3. Heat sink dimensions are specified in [Section 14.9.3](#).
4. Natural Convection (Still Air), Heat sink attached.
5.  $\Psi_{JT}$  is given as maximum value for a worst-case X550 scenario and might vary to a lesser value in some scenarios.

**Table 14-2. The X550 Absolute Thermal Maximum Rating (°C)**

| Application | Estimated TDP (W) <sup>1</sup> | Tcase Max <sup>2</sup> (°C) <sup>3</sup> |
|-------------|--------------------------------|------------------------------------------|
| X550        | 11.5 W @ 105 Tj max            | 107                                      |

1. Power value listed here is estimated maximum power, also known as TDP. TDP is a system design target associated with the maximum component operating temperature specifications. Maximum power values are determined based on typical DC electrical specification and maximum ambient temperature for a worst-case realistic application running at maximum utilization.
2. Tcase Max-hs is defined as the maximum case temperature with the default enhanced thermal solution attached.
3. This is a not to exceed maximum allowable case temperature.

## 14.7.1 Case Temperature

The X550 is designed to operate properly as long as the Tcase rating is not exceeded. [Section 14.10.1](#) discusses proper guidelines for measuring the case temperature.

## 14.8 Thermal Attributes

**Important:** Information contained in this section is preliminary and subject to change without notice.

### 14.8.1 Designing for Thermal Performance

[Section 14.12](#) and [Section 14.13](#) describe the PCB and system design recommendations required to achieve the proper X550 thermal performance.

## 14.8.2 Typical System Definition

A system with the following attributes was used to generate thermal characteristics data:

- A heat sink case with the default enhanced thermal solution (see [Section 14.9](#)).
- Six-layer, 4.5 x 4 inch PCB.

**Note:** Keep the following in mind when reviewing the data that is included in this sub-section:

- All data is preliminary and is not validated against physical samples.
- Your system design might be significantly different.
- A larger board with more than six copper layers might improve the X550 thermal performance.

## 14.8.3 Package Mechanical Attributes

The X550 is packaged in a 25 mm or 17 mm FCBGA as shown in [Section 12.7.4](#).

### 14.8.3.1 Package Thermal Characteristics

Refer to [Table 14-3](#) for an aid in determining the optimum airflow and heat sink combination for the X550. See [Section 12.2.2](#) for more details.

[Table 14-3](#) lists Tcase as a function of airflow and ambient temperature at the TDP for a typical X550 system. Again, your system design might vary considerably from the typical system board environment used to generate the values listed in [Table 14-1](#) and [Table 14-2](#).

**Note:** Thermal models are available upon request (Flotherm\*). Contact your local Intel sales representative for the X550 thermal models.

**Table 14-3. X550 Expected Tcase (°C) for High Heat Sink in Figure 14-3 at 11.5 W (JEDEC Card)**

| Ambient/<br>Airflow (LFM) | 0     | 50    | 100   | 150   | 200   | 250   | 300   | 350   | 400   |
|---------------------------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| 45                        | 121.7 | 113.6 | 98.67 | 90.27 | 85.04 | 81.37 | 78.61 | 76.42 | 74.64 |
| 50                        | 125.6 | 117.3 | 103   | 94.82 | 89.7  | 86.09 | 83.38 | 81.23 | 79.47 |
| 55                        | 129.8 | 120.9 | 107.4 | 99.36 | 94.34 | 90.81 | 88.14 | 86.02 | 84.29 |
| 60                        | 133   | 124.2 | 111.6 | 103.9 | 98.97 | 95.51 | 92.9  | 90.81 | 89.1  |
| 65                        | 133.5 | 127.4 | 115.8 | 108.3 | 103.6 | 100.2 | 97.63 | 95.59 | 93.91 |
| 70                        | 135.9 | 131   | 120   | 112.8 | 108.2 | 104.9 | 102.4 | 100.4 | 98.7  |
| 75                        | 139.1 | 134.7 | 124.1 | 117.3 | 112.8 | 109.5 | 107.1 | 105.1 | 103.5 |
| 80                        | 142.2 | 138.6 | 128.2 | 121.7 | 117.2 | 114.2 | 111.8 | 109.9 | 108.3 |
| 85                        | 145.6 | 142.5 | 132.3 | 126.1 | 121.9 | 118.8 | 116.5 | 114.6 | 113   |

**Note:** The red blocked value(s) indicate airflow/ambient combinations that exceed the allowable junction temperature for the X550 at 11.5 W.

## 14.9 Thermal Enhancements

**Important:** Information contained in this section is preliminary and subject to change without notice.

One method frequently used to improve thermal performance is to increase the device surface area by attaching a metallic heat sink to the component top. Increasing the surface area of the heat sink reduces the thermal resistance from the heat sink to the air, which increases heat transfer.

### 14.9.1 Clearances

To be effective, a heat sink should have a pocket of air around it that is free of obstructions. Though each design can have unique mechanical restrictions, the recommended clearances for a heat sink used with the X550 are shown in [Figure 14-1](#) assuming one of the 40 x 40 mm reference heat sinks is selected. Retention clip selection is open, and example keep-outs and board through holes are shown in [Figure 14-1](#) and [Figure 14-2](#) for a torsion retention clip.

**Figure 14-1. X550 Heat Sink Keep Out Restrictions (Top Side Keep Out)**

**Figure 14-2. X550 Heat Sink Keep Out Restrictions (Bottom Side Keep Out)**

## 14.9.2 Default Enhanced Thermal Solution

If you have no control over the end-user's thermal environment, or if you wish to bypass the thermal modeling and evaluation process, use the default enhanced thermal solutions (see [Figure 14-2](#) and [Figure 14-3](#)). These solutions replicate the performance listed in [Figure 14-3](#) at the TDP. If, after implementing the recommended enhanced thermal solution, the case temperature continues to exceed allowable values, additional cooling is needed. This additional cooling can be achieved by improving airflow to the component and/or adding additional thermal enhancements.

## 14.9.3 Extruded Heat Sinks

If required, the following extruded heat sinks are the suggested X550 thermal solutions ([Figure 14-3](#)). Also, see [Figure 14-1](#) and [Figure 14-2](#) for heat sink information.

**Figure 14-3. X550 Extruded Heat Sink**

## 14.9.4 Attaching the Extruded Heat Sink

The extruded heat sink can be attached using clips or pins with a phase change thermal interface material.

### 14.9.4.1 Clips

A well-designed clip, in conjunction with a thermal interface material (tape, grease, etc.) often offers the best combination of mechanical stability and rework ability. Use of a clip requires significant advance planning as mounting holes are required in the PCB.

### 14.9.4.2 Thermal Interface (PCM45 Series)

The recommended thermal interface is PCM45 Series from Honeywell\*. The PCM45 Series thermal interface pads are phase change materials formulated for use in high performance devices requiring minimum thermal resistance for maximum heat sink performance and component reliability. These pads consist of an electrically non-conductive, dry film that softens at device operating temperatures resulting in greasy-like performance. However, Intel has not fully validated the PCM45 Series TIM.

Each PCA, system and heat sink combination varies in attach strength. Carefully evaluate the reliability of double sided thermal interface tape attachments prior to high-volume use (see [Section 14.9.5](#)).

### 14.9.4.3 Avoid Damaging Die-side Capacitors with Heat Sink Attach

Capacitors on the die side are not protected and can be damaged during heat sink attach. If the heat sink is tilted from the die, it is possible that the heat sink will make contact with the capacitors prior to making contact with the package substrate. [Figure 14-4](#) shows how the capacitors can be exposed to heat sink contact by drawing a plane from the die edge to the substrate edge. [Figure 14-5](#) shows an example of the damage caused by heat sink contact. It is recommended that heat sinks be attached vertically, with the heat sink bottom surface parallel to the die surface to avoid contact with the capacitors.

**Figure 14-4. Die-Side Capacitors Exposed to Heat Sink Contact**

**Figure 14-5. Damage Caused by Heat Sink Contact**

#### **14.9.4.4 Maximum Static Normal Load**

The X550 has a bare die that is capable of sustaining a maximum static normal load of 15 lbf (67N). This load is a uniform compressive load in a direction perpendicular to the die top surface. This mechanical load limit must not be exceeded during heat sink installation, mechanical stress testing, standard shipping conditions, and/or any other use condition. Note that the heat sink attach solution must not include continuous stress to the package, with the exception of a uniform load to maintain the heat-sink-to-package thermal interface. This load specification is based on limited testing for design characterization, and is for the package only.

## 14.9.5 Reliability

Each PCA, system and heat sink combination varies in attach strength and long-term adhesive performance. Carefully evaluate the reliability of the completed assembly prior to high-volume use. Some reliability recommendations are listed in [Table 14-4](#).

**Table 14-4. Reliability Validation**

| Test <sup>1</sup>     | Requirement                                                                      | Pass/Fail Criteria <sup>2</sup> |
|-----------------------|----------------------------------------------------------------------------------|---------------------------------|
| Mechanical Shock      | 50 G trapezoidal, board level<br>11 ms, 3 shocks/axis                            | Visual and Mechanical Check.    |
| Random Vibration      | 7.3 G, board level<br>45 minutes/axis, 50 to 2000 Hz                             | Visual and Mechanical Check.    |
| High-Temperature Life | 85 °C<br>2000 hours total<br>Checkpoints occur at 168, 500, 1000, and 2000 hours | Visual and Mechanical Check.    |
| Thermal Cycling       | Per-target environment<br>(for example: -40 °C to +85 °C)<br>500 cycles          | Visual and Mechanical Check.    |
| Humidity              | 85% relative humidity<br>85 °C, 1000 hours                                       | Visual and Mechanical Check.    |

1. These tests were performed on a sample size of at least 12 assemblies from 3 lots of material (total = 36 assemblies).
2. Additional pass/fail criteria can be added at your discretion.

## 14.9.6 Thermal Interface Management for Heat Sink Solutions

To optimize the X550 heat sink design, it is important to understand the interface between the silicon die and the heat sink base. Thermal conductivity effectiveness depends on the following:

- Bond line thickness.
- Interface material area.
- Interface material thermal conductivity.

### 14.9.6.1 Bond Line Management

The gap between the silicon die and the heat sink base impacts heat sink solution performance. The larger the gap between the two surfaces, the greater the thermal resistance. The thickness of the gap is determined by the flatness of both the heat sink base and the silicon die, plus the thickness of the thermal interface material (for example, PSA, thermal grease, epoxy) used to join the two surfaces.

### 14.9.6.2 Interface Material Performance

The following factors impact the performance of the interface material between the silicon die and the heat sink base:

- Thermal resistance of the material.
- Wetting/filling characteristics of the material.

#### 14.9.6.2.1 Thermal Resistance of the Material

Thermal resistance describes the ability of the thermal interface material to transfer heat from one surface to another. The higher the thermal resistance, the less efficient the heat transfer. The thermal resistance of the interface material has a significant impact on the thermal performance of the overall thermal solution. The higher the thermal resistance, the larger the temperature drop required across the interface.

#### 14.9.6.2.2 Wetting/Filling Characteristics of the Material

The wetting/filling characteristic of the thermal interface material is its ability to fill the gap between the silicon die top surface and the heat sink. Since air is an extremely poor thermal conductor, the more completely the interface material fills the gaps, the lower the temperature-drop across the interface, increasing the efficiency of the thermal solution.

## 14.10 Measurements for Thermal Specifications

Determining the thermal properties of the system requires careful case temperature measurements. Guidelines for measuring the X550 case temperature are provided in [Section 14.10.1](#).

### 14.10.1 Case Temperature Measurements

Maintain the X550 T<sub>case</sub> at or below the maximum case temperatures listed in [Table 14-2](#) to ensure functionality and reliability. Special care is required when measuring the T<sub>case</sub> temperature to ensure an accurate temperature measurement. Use the following guidelines when making T<sub>case</sub> measurements:

- Measure the surface temperature of the case in the geometric center of the case top.
- Calibrate the thermocouples used to measure T<sub>case</sub> before making temperature measurements.
- Use 36-gauge (maximum) K-type thermocouples.

Care must be taken to avoid introducing errors into the measurements when measuring a surface temperature that is a different temperature from the surrounding local ambient air. Measurement errors can be due to a poor thermal contact between the thermocouple junction and the surface of the package, heat loss by radiation, convection, conduction through thermocouple leads, and/or contact between the thermocouple cement and the heat sink base (if used).

#### 14.10.1.1 Attaching the Thermocouple (No Heat Sink)

The following approach is recommended to minimize measurement errors for attaching the thermocouple with no heat sink:

- Use 36-gauge or smaller-diameter K-type thermocouples.
- Ensure that the thermocouple has been properly calibrated.
- Attach the thermocouple bead or junction to the top surface of the package (case) in the center of the heat spreader using high thermal conductivity cements.

**Note:** It is critical that the entire thermocouple lead be butted tightly to the heat spreader.

Attach the thermocouple at a 0° angle if there is no interference with the thermocouple attach location or leads (see [Figure 14-6](#)). This is the preferred method and is recommended for use with packages without a heat sink.

**Figure 14-6. Technique for Measuring Tcase with 0° Angle Attachment and No Heat Sink**

### 14.10.1.2 Attaching the Thermocouple (Heat Sink)

The following approach is recommended to minimize measurement errors for attaching the thermocouple with heat sink:

- Use 36-gauge or smaller diameter K-type thermocouples.
- Ensure that the thermocouple is properly calibrated.
- Attach the thermocouple bead or junction to the case's top surface in the geometric center using high thermal conductivity cement.

**Note:** It is critical that the entire thermocouple lead be butted tightly against the case.

- Attach the thermocouple at a 90° angle if there is no interference with the thermocouple attach location or leads (see [Figure 14-7](#)). This is the preferred method and is recommended for use with packages with heat sinks.
- For testing purposes, a hole (no larger than 0.150 inches in diameter) must be drilled vertically through the center of the heat sink to route the thermocouple wires out.
- Ensure there is no contact between the thermocouple cement and heat sink base. Any contact affects the thermocouple reading.

**Figure 14-7. Technique for Measuring Tcase with 90° Angle Attachment**

## 14.11 Conclusion

Increasingly complex systems require better power dissipation. Heat can be dissipated using improved system cooling, selective use of ducts, passive or active heat sinks, or any combination.

The simplest and most cost-effective method is to improve the inherent system cooling characteristics through careful design and placement of fans, vents, and ducts. When additional cooling is required, thermal enhancements can be implemented in conjunction with enhanced system cooling. The size of the fan or heat sink can be varied to balance size and space constraints with acoustic noise.

This described the conditions and requirements to properly design a cooling solution for systems implementing the X550. Properly designed solutions provide adequate cooling to maintain the X550 case temperature at or below those listed in [Table 14-2](#). Ideally, this is accomplished by providing a low local ambient temperature and creating a minimal thermal resistance to that local ambient temperature. Alternatively, heat sinks might be required if case temperatures exceed those listed in [Table 14-2](#).

By maintaining the X550 case temperature at or below those recommended in this section, the X550 will function properly and reliably.

Use this section to understand the X550 thermal characteristics and compare them to your system environment. Measure the X550 case temperatures to determine the best thermal solution for your design.

## 14.12 Heat Sink and Attach Suppliers

## 14.13 PCB Guidelines

The following general PCB design guidelines are recommended to maximize thermal performance of FCBGA packages:

- When connecting ground (thermal) vias to the ground planes, do not use thermal-relief patterns.
- Thermal-relief patterns are designed to limit heat transfer between vias and the copper planes, thus constricting the heat flow path from the component to the ground planes in the PCB.
- As board temperature also has an effect on the thermal performance of the package, avoid placing the X550 adjacent to high-power dissipation devices.
- If airflow exists, locate the components in the mainstream of the airflow path for maximum thermal performance. Avoid placing the components downstream, behind larger devices or devices with heat sinks that obstruct the air flow or supply excessively heated air.

**Note:** The previous information is provided as a general guideline to help maximize the thermal performance of the components.

**NOTE:**      *This page intentionally left blank.*

## 15.0 Diagnostics

### 15.1 JTAG Test Mode Description

The X550 includes a JTAG (TAP) port compliant with the *IEEE Standard Test Access Port and Boundary Scan Architecture 1149.1 Specification*. The TAP controller is accessed serially through five dedicated pins: TCK, TMS, TDI, TDO, and TRST\_N. TMS, TDI, and TDO operate synchronously with TCK. TCK is independent of all other device clocks.

This interface can be used for test and debug purposes. System board interconnects can be DC tested using the boundary scan logic in pads. [Table 15-1](#) shows TAP controller related pin descriptions. [Table 15-2](#) describes the TAP instructions supported.

**Table 15-1. TAP Controller Pins**

| Signal | I/O | Description                                                                                                                                                                                                |
|--------|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TCK    | In  | Test clock input for the test logic defined by IEEE1149.1. If utilizing JTAG, connect to this signal ground through a 1 K $\Omega$ pull-down resistor.                                                     |
| TDI    | In  | Test Data Input. Serial test instructions and data are received by the test logic at this pin. If utilizing JTAG, connect this signal to VCC33 through a 1 K $\Omega$ pull-up resistor.                    |
| TDO    | O/D | Test Data Output. The serial output for the test instructions and data from the test logic defined in IEEE1149.1. If utilizing JTAG, connect this signal to VCC33 through a 1 K $\Omega$ pull-up resistor. |
| TMS    | In  | Test Mode Select input. The signal received at JTMS is decoded by the TAP controller to control test operations.                                                                                           |
| TRST_N | In  | JTAG Reset Input. Active low reset for the JTAG port.                                                                                                                                                      |

**Table 15-2. Main TAP Instructions Supported**

| Instruction         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Comment                      |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|
| BYPASS              | The BYPASS command selects the Bypass Register, a single bit register connected between TDI and TDO pins. This allows more rapid movement of test data to and from other components in the system.                                                                                                                                                                                                                                                                                                                                                                                                                                             | IEEE 1149.1 Std. Instruction |
| EXTEST              | The EXTEST Instruction allows circuitry or wiring external to the devices to be tested. Boundary-scan Register Cells at outputs are used to apply stimulus while Boundary-scan cells at input pins are used to capture data.                                                                                                                                                                                                                                                                                                                                                                                                                   | IEEE 1149.1 Std. Instruction |
| SAMPLE /<br>PRELOAD | The SAMPLE/PRELOAD instruction is used to allow scanning of the boundary scan register without causing interference to the normal operation of the device. Two functions can be performed by use of the Sample/Preload instruction. <ul style="list-style-type: none"><li>• SAMPLE – allows a snapshot of the data flowing into and out of a device to be taken without affecting the normal operation of the device.</li><li>• PRELOAD – allows an initial pattern to be placed into the boundary scan register cells. This allows initial known data to be present prior to the selection of another boundary-scan test operation.</li></ul> | IEEE 1149.1 Std. Instruction |
| IDCODE              | The IDCODE instruction is forced into the parallel output latches of the instruction register during the Test-Logic-Reset TAP state. This allows the device identification register to be selected by manipulation of the broadcast TMS and TCK signals for testing purposes, as well as by a conventional instruction register scan operation.<br>The ID code value for the X550 A0 is 0x11562013 (Intel's Vendor ID = 0x09, Device ID = 0x1562, Rev ID = 0x0)<br>The ID code value for the X550 B0 is 0x21562013 (Intel's Vendor ID = 0x09, Device ID = 0x1562, Rev ID = 0x1)                                                                | IEEE 1149.1 Std. Instruction |
| HIGHZ               | The HIGHZ instruction is used to force all outputs of the device (except TDO) into a high impedance state. This instruction selects the Bypass Register to be connected between TDI and TDO in the Shift-DR controller state.                                                                                                                                                                                                                                                                                                                                                                                                                  | IEEE 1149.1 Std. Instruction |

## 15.2 MAC Loopback Operations

Loopback operations are supported by the X550 to assist with system and the X550 debug. Loopback operation can be used to test transmit and receive aspects of software drivers, as well as to verify electrical integrity of the connections between the X550 and the system (such as PCIe bus connections, etc.).

### 15.2.1 Tx->Rx MAC Loopback

This loopback is closed on the internal XGMII interface of the MAC core.

To configure the X550 for Tx->Rx loopback operation:

- Disable auto-negotiation in PHY register bit 7.0.C.
- Operate only at 10 GbE speed while no link partner is present. For other speeds, establish the link with a link partner at the desired speed while performing Tx -> Rx MAC loopback.
- In the MACC register, set the *FLU* bit to 1b to force link up.
- In the HLREG0 register, set the *LPBK* bit to 1b.

### 15.2.2 Rx->Tx MAC Loopback

This loopback is closed in the internal XGMII interface.

To configure the X550 for Rx->Tx loopback operation, the *MAC\_RX2TX\_LPBK\_EN* bit in the MACC register should be set to 1b.

For loopback to be functional a functional link (with the partner) should be achieved (sync and alignment).

Link configuration should be done as in regular functional mode (see [Section 4.6.3](#)). All link modes can be configured.

Loopback limitation notes:

- Short preamble with minimal IPG is not supported with loopback operation.
- Transmitted data might violate the minimum IPG specification requirements.

**NOTE:**      ***This page intentionally left blank.***

## 16.0 Glossary and Acronyms

| Term           | Definition                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1's complement | A system known as ones' complement can be used to represent negative numbers in a binary system. The ones' complement form of a negative binary number is the bitwise NOT applied to it.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 1000BASE-BX    | 1000BASE-BX is the PICMG 3.1 electrical specification for transmission of 1 Gb/s Ethernet or 1 Gb/s fibre channel encoded data over the backplane.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 1000BASE-CX    | 1000BASE-X over specialty shielded 150 W balanced copper jumper cable assemblies as specified in IEEE 802.3 Clause 39.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 1000BASE-T     | 1000BASE-T is the specification for 1 Gb/s Ethernet over category 5e twisted pair cables as defined in IEEE 802.3 clause 40.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 2's complement | A system of two's-complement arithmetic represents negative integers by counting backwards and wrapping around. Any number whose left-most bit is 1 is considered negative.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| AAD            | Additional Authentication Data input, which is authenticated data that must be left un-encrypted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| ACK            | Acknowledgment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| ACPI           | Advanced Configuration and Power Interface — ACPI reset is also known as D3hot-D0 transition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Corner case             | Is a problem or situation that occurs only outside of normal operating parameters — specifically one that manifests itself when multiple environmental variables or conditions are simultaneously at extreme levels.<br><br>For example, a computer server may be unreliable, but only with the maximum complement of 64 processors, 512 GB of memory, and over 10,000 signed-on users. From Wiki.                                                                                                                                                                                                                                   |
| CPID                    | Congestion Point Identifier –which should include the congestion point Ethernet MAC Address, as well as a local identifier for the local congestion entity, usually a queue in the switch.                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| CRC                     | Cyclic Redundancy Check<br><br>A cyclic redundancy check (CRC) is a type of function that takes as input a data stream of unlimited length and produces as output a value of a certain fixed size. The term CRC is often used to denote either the function or the function's output. A CRC can be used in the same way as a checksum to detect accidental alteration of data during transmission or storage. CRCs are popular because they are simple to implement in binary hardware, are easy to analyze mathematically, and are particularly good at detecting common errors caused by noise in transmission channels. | ESP              | <p>IP Encapsulating Security Payload — An IPsec header providing encryption and authentication capabilities defined in RFC 4303. The Encapsulating Security Payload (ESP) extension header provides origin authenticity, integrity, and confidentiality protection of a packet. ESP also supports encryption-only and authentication-only configurations, but using encryption without authentication is strongly discouraged. Unlike the AH header, the IP packet header is not accounted for. ESP operates directly on top of IP, using IP protocol number 50. ESP fields:</p> <ul style="list-style-type: none"> <li>• Security Parameters Index (SPI): See AH</li> <li>• Sequence Number: See AH</li> <li>• Payload Data: See AH</li> <li>• Padding: Used with some block ciphers to pad the data to the full length of a block.</li> <li>• Pad Length: Size of padding in bytes.</li> <li>• Next Header: Identifies the protocol of the transferred data.</li> <li>• Authentication Data: Contains the data used to authenticate the packet.</li> </ul> |
| EUI              | IEEE defined 64-bit Extended Unique Identifier                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Extension Header | IPv6 protocol.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Fail-over        | Fail-over is the ability to detect that the LAN connection on one port is lost, and enable the other port for traffic.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| FC               | Fiber Channel                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| FC               | Flow Control                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| FC Exchange      | Complete Fiber Channel Read or Fiber Channel Write flow. It starts with the read or write requests by the initiator (the host system) till the completion indication from the target (the remote disk).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| FC Frame         | Fiber Channel Frames are the smallest units sent between the initiator and the target. The FC-FS-2 specification defined the maximum frame size as 2112 bytes. Each Fiber Channel frame includes an FC header and optional FC payload. It can also may include Extended headers and FC optional headers. Extended headers are not expected in FCoE network and FC optional headers may not be used as well.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| FC Sequence      | A Fiber Channel Exchange is composed of multiple Fiber Channel sequences. Fiber Channel Sequence can be a single or multiple frames that are sent by the initiator or the target. Each FC Sequence has a unique "Sequence ID".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| FCoE             | Fiber Channel over Ethernet                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| FCP_RSP Frame    | Fiber Channel control Frames that are sent from the target to the initiator which defines the completion of an FC read or write exchange.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| FCS              | Frame Check Sequence of Ethernet frames (also known as CRC)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| FEC              | Forward Error Correction                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| FEXT             | Far End Crosstalk                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Firmware (FW)    | Embedded code on the LAN controller that is responsible for the implementation of the NC-SI protocol and pass-through functionality.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| FLR              | Function level reset An OS in a VM must have complete control over a device, including its initialization, without interfering with the rest of the functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Host Interface | RAM on the LAN controller that is shared between the firmware and the host. RAM is used to pass commands from the host to firmware and responses from the firmware to the host.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| HPC            | High-Performance Computing                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| HT core option | Hyper Thread Intel's trademark for implementation of the simultaneous multi-threading technology on the Pentium 4 micro architecture. It is a more advanced form of Super-threading that debuted on the Intel Xeon processors and was later added to Pentium 4 processors. The technology improves processor performance under certain workloads by providing useful work for execution units that would otherwise be idle, for example during a cache miss. A Pentium 4 with Hyper-Threading enabled is treated by the operating system as two processors instead of one. From Wiki                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| IP Tunneling   | IP tunneling is the process of embedding one IP packet inside of another, for the purpose of simulating a physical connection between two remote networks across an intermediate network.<br>IP tunnels are often used in conjunction with IPsec protocol to create a VPN between two or more remote networks across a "hostile" network such as the Internet.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| IPC            | Inter Processor Communication                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| IPsec          | IP Security is a suite of protocols for securing Internet Protocol (IP) communications by authenticating and/or encrypting each IP packet in a data stream. IPsec also includes protocols for cryptographic key establishment.<br>IPsec is implemented by a set of cryptographic protocols for (1) securing packet flows and (2) internet key exchange. There are two families of key exchange protocols.<br>The IP security architecture uses the concept of a security association as the basis for building security functions into IP. A security association is simply the bundle of algorithms and parameters (such as keys) that is being used to encrypt a particular flow. The actual choice of algorithm is left up to the users. A security parameter index (SPI) is provided along with the destination address to allow the security association for a packet to be looked up.<br>For multicast, therefore, a security association is provided for the group, and is duplicated across all authorized receivers of the group. There may be more than one security association for a group, using different SPIs, thereby allowing multiple levels and sets of security within a group. Indeed, each sender can have multiple security associations, allowing authentication, since a receiver can only know that someone knowing the keys sent the data. Note that the standard does not describe how the association is chosen and duplicated across the group; it is assumed that a responsible party will make the choice. From Wiki |
| iSCSI          | Internet SCSI (iSCSI) is a network protocol standard, officially ratified on 2003-02-11 by the Internet Engineering Task Force, that allows the use of the SCSI protocol over TCP/IP networks. iSCSI is a transport layer protocol in the SCSI-3 specifications framework. Other protocols in the transport layer include SCSI Parallel Interface (SPI), Serial Attached SCSI (SAS) and Fibre Channel. From Wiki.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| LLC header                | 802.2 defines a special header that includes a SNAP (subnetwork access protocol) header + EtherType. Some protocols, particularly those designed for the OSI networking stack, operate directly on top of 802.2 LLC, which provides both datagram and connection-oriented network services. This 802.2 header is currently embedded in modern 802.3 frames (Ethernet II frames, aka. DIX frames).<br>The LLC header includes two additional eight-bit address fields, called service access points or SAPs in OSI terminology; when both source and destination SAP are set to the value 0xAA, the SNAP service is requested. The SNAP header + EtherType allows EtherType values to be used with all IEEE 802 protocols, as well as supporting private protocol ID spaces. In IEEE 802.3x-1997, the IEEE Ethernet standard was changed to explicitly allow the use of the 16-bit field after the Ethernet MAC Addresses to be used as a length field or a type field. | salt       | In cryptography, a salt consists of random bits used as one of the inputs to a key derivation function. Sometimes the initialization vector, a previously generated (preferably random) value, is used as a salt. The other input is usually a password or passphrase. The output of the key derivation function is often stored as the encrypted version of the password. A salt value can also be used as a key for use in a cipher or other cryptographic algorithm. A salt value is typically used in a hash function. from Wiki                                                                                                                                                                 |

| SC         | Secure Channel (SC) — A security relationship used to provide security guarantees for frames transmitted from one member of a CA to the others. An SC is supported by a sequence of SAs thus allowing the periodic use of fresh keys without terminating the relationship.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| SCI        | Secure Channel Identifier — A globally unique identifier for a secure channel, comprising a globally unique Ethernet MAC Address and a Port Identifier, unique within the system allocated that address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| SCL signal | SM Bus Clock                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| SCSI       | Small Computer System Interface is a set of standards for physically connecting and transferring data between computers and peripheral devices. The SCSI standards define commands, protocols, and electrical and optical interfaces. SCSI is most commonly used for hard disks and tape drives, but it can connect a wide range of other devices, including scanners, and optical drives (CD, DVD, etc. From Wiki.                                                                                                                                                                                                                                                                                  |

| SMBus      | System Management Bus — A bus that carries various manageability components, including the LAN controller, BIOS, sensors and remote-control devices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| SN         | Sequence Number — Contains a counter value that increases by one for each Ethernet frame sent.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| SNAP       | Subnetwork Access Protocol                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| SNMP       | Standard Network Management Protocol                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| SoL        | Serial Over LAN — A mechanism that enables the input and output of the serial port of a managed system to be redirected via an IPMI (Internet Protocol Multicast Initiative) session over IP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| SPD        | Smart Power Down                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| SPI        | The Security Parameter Index is an identification tag added to the header while using IPsec for tunneling the IP traffic. This tag helps the kernel discern between two traffic streams where different encryption rules and algorithms may be in use.<br>The SPI (as per RFC 2401) is an essential part of an IPsec SA (Security Association) because it enables the receiving system to select the SA under which a received packet is processed. An SPI has only local significance, since is defined by the creator of the SA; an SPI is generally viewed as an opaque bit string. However, the creator of an SA may interpret the bits in an SPI to facilitate local processing. from Wikipedia |

| Term                        | Definition                                                                                                                                                                                                                                                                |

| VMDq2          | SW switch acceleration mode — Central management of the networking resources by an IOVM or by the VMM.<br>Virtual Machine Devices queue (VMDq) is a mechanism to share I/O resources among several consumers. For example, in a virtual system, multiple OSs are loaded and each executes as though the whole system's resources were at its disposal. However, for the limited number of I/O devices, this presents a problem because each OS may be in a separate memory domain and all the data movement and device management has to be done by a VMM (Virtual Machine Monitor). VMM access adds latency and delay to I/O accesses and degrades I/O performance. VMDs (Virtual Machine Devices) are designed to reduce the burden of VMM by making certain functions of an I/O device shared and thus can be accessed directly from each guest OS or Virtual Machine (VM). From Nahum |

## A.1.2 IP and TCP/UDP Headers for TSO

This section outlines the format and content for the IP, TCP and UDP headers. The X550 requires baseline information from the device driver to construct the appropriate header information during the segmentation process.

Header fields that are modified by the X550 are highlighted in the figures below.

**Note:** The IP header is first shown in the traditional (i.e. RFC 791) representation, and because byte and bit ordering is confusing in that representation, the IP header is also shown in Little Endian format. The actual data is fetched from memory in Little Endian format.

|                                                            |  |               |  |                     |  |  |  |                                           |  |  |  |                 |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

**Figure A-2. IPv4 Header (Little Endian Order - Byte 0 First On the Wire)**

Identification is increased on each packet.

Flags Field Definitions:

The Flags field is defined below. Note that hardware does not evaluate or change these bits.

- MF - More Fragments
- NF - No Fragments
- Reserved

The X550 does TCP segmentation, not IP Fragmentation. IP Fragmentation may occur in transit through a network's infrastructure.

Figure A-4. IPv6 Header (Little Endian Order - Byte 0 First On the Wire)

A TCP or UDP frame uses a 16-bit wide one's complement checksum. The checksum word is computed on the outgoing TCP or UDP header and payload, and on the Pseudo Header. Details on checksum computations are provided in [Section 7.2.4.6](#).

**Note:** TCP and UDP over IPv6 requires the use of checksum, where it is optional for UDP over IPv4.

**Note:** The TCP header is first shown in the traditional (i.e. RFC 793) representation, and because byte and bit ordering is confusing in that representation, the TCP header is also shown in Little Endian format. The actual data is fetched from memory in Little Endian format.

**Figure A-6. TCP Header (Little Endian)**

The TCP header is always a multiple of 32-bit words. TCP options may occupy space at the end of the TCP header and are a multiple of 8 bits in length. All options are included in the checksum.

The checksum also covers a 96-bit pseudo header prefixed to the TCP Header (see [Figure A-7](#) below). For IPv4 packets, this pseudo header contains the IP Source Address, the IP Destination Address, the IP Protocol field, and TCP Length. Software pre-calculates the partial pseudo header sum, that includes IPv4 SA, DA and protocol types, but NOT the TCP length, and stores this value into the TCP *Checksum* field of the packet. For both IPv4 and IPv6, hardware needs to factor in the TCP length to the software supplied pseudo header partial checksum.

**Note:** When calculating the TCP pseudo header, the byte ordering can be tricky. One common question is whether the *Protocol ID* field is added to the “lower” or “upper” byte of the 16-bit sum. The *Protocol ID* field should be added to the least significant byte (LSB) of the 16-bit pseudo header sum, where the most significant byte (MSB) of the 16-bit sum is the byte that corresponds to the first checksum byte out on the wire.

The *TCP Header Length* field is the TCP header length including option fields plus the data length in bytes, which is calculated by hardware on a frame-by-frame basis. The TCP Length does not count the 12 bytes of the pseudo header. The TCP length of the packet is determined by hardware as:

$$\text{TCP Length} = \min(\text{MSS}, \text{PAYLOADLEN}) + \text{L5\_LEN}$$

The two flags that may be modified are defined as:

- **PSH** — Receiver should pass this data to the app without delay.
- **FIN** — Sender is finished sending data.

The handling of these flags is described in [Section 7.2.4.7](#).

“Payload” is normally MSS except for the last packet where it represents the remainder of the payload.

|--------------------------------|-------------|
| IPv6 Source Address            |             |
| IPv6 Final Destination Address |             |
| TCP/UDP Packet Length          |             |
| Zero                           | Next Header |

**Figure A-8. TCP/UDP Pseudo Header Content for IPv6 (Traditional Representation)**

**Note:** From RFC2460:

- If the IPv6 packet contains a Routing header, the Destination Address used in the pseudo-header is that of the final destination. At the originating node, that address is in the last element of the Routing header; at the recipient(s), that address is in the *Destination Address* field of the IPv6 header.
- The Next Header value in the pseudo-header identifies the upper-layer protocol (e.g., 6 for TCP, or 17 for UDP). It differs from the Next Header value in the IPv6 header if there are extension headers between the IPv6 header and the upper-layer header.
- The Upper-Layer Packet Length in the pseudo-header is the length of the upper-layer header and data (e.g., TCP header plus TCP data). Some upper-layer protocols carry their own length information (e.g., the *Length* field in the UDP header); for such protocols, that is the length used in the pseudo-header. Other protocols (such as TCP) do not carry their own length information, in which case the length used in the pseudo-header is the Payload Length from the IPv6 header, minus the length of any extension headers present between the IPv6 header and the upper-layer header.
- Unlike IPv4, when UDP packets are originated by an IPv6 node, the UDP checksum is not optional. That is, whenever originating a UDP packet, an IPv6 node must compute a UDP checksum over the packet and the pseudo-header, and, if that computation yields a result of zero, it must be changed to hex FFFF for placement in the UDP header. IPv6 receivers must discard UDP packets containing a zero checksum, and should log the error.

A type 0 Routing header has the following format:

| Next Header                   | Hdr Ext Len | Routing Type<br>"0" | Segments Left<br>"n" |
|-------------------------------|-------------|---------------------|----------------------|
| Reserved                      |             |                     |                      |
| Address[1]                    |             |                     |                      |
| Address[2]                    |             |                     |                      |
| ...                           |             |                     |                      |
| Final Destination Address [n] |             |                     |                      |

**Figure A-9. IPv6 Routing Header (Traditional Representation)**

- **Next Header** — 8-bit selector. Identifies the type of header immediately following the Routing header. Uses the same values as the IPv4 protocol field [RFC-1700 et seq.].
- **Hdr Ext Len** — 8-bit unsigned integer. Length of the Routing header in 8-octet units, not including the first 8 octets. For the Type 0 Routing header, Hdr Ext Len is equal to two times the number of addresses in the header.
- **Routing Type** — 0.
- **Segments Left** — 8-bit unsigned integer. Number of route segments remaining (i.e., number of explicitly listed intermediate nodes still to be visited before reaching the final destination). Equal to "n" at the source node.

- **Reserved** — 32-bit reserved field. Initialized to zero for transmission; ignored on reception.
- **Address[1...n]** — Vector of 128-bit addresses, numbered 1 to n.

The UDP header is always 8 bytes in size with no options.

| Checksum         |                 |                 |                 |
| Length           |                 |                 |                 |

**Figure A-11. UDP Header (Little Endian Order)**

UDP pseudo header has the same format as the TCP pseudo header. The pseudo header prefixed to the UDP header contains the IPv4 source address, the IPv4 destination address, the IPv4 protocol field, and the UDP length (same as the TCP Length discussed above). This checksum procedure is the same as is used in TCP.

Unlike the TCP checksum, the UDP checksum is optional (for IPv4). Software must set the *TXSM* bit in the TCP/IP Context Transmit Descriptor to indicate that a UDP checksum should be inserted. Hardware does not overwrite the UDP checksum unless the *TXSM* bit is set.

### A.1.3 Magic Packet

The Magic Packet is a broadcast frame, but could also be a Multicast or Unicast Ethernet MAC Addresses. The X550 accepts this packet if it matches any of its pre-programmed Ethernet MAC Addresses. Magic packet can be sent over a variety of connectionless protocols (usually UDP or IPX). The Magic packet pattern is composed of the following sequences:

- Synchronization stream composed of 6 bytes equal to 0xFF 0xFF 0xFF 0xFF 0xFF 0xFF
- Unique pattern composed of 16 times the end node Ethernet MAC Address. The X550 expect for the Ethernet MAC Address stored in the RAL[0] and RAH[0] registers.

The X550 looks for the synchronization pattern and the sequence of 16 Ethernet MAC Addresses. It does not check the packet content and the length of the header that precedes the magic pattern nor any data that follows it.

## A.2 Packet Types for Packet Split Filtering

The following packet types are supported by the 'Packet Split' feature in the X550. This section describes the packets from the 'split-header' point of view. This means that when describing the different fields that are checked and compared, it emphasizes only the fields that are needed to calculate the header length. This document describes the checks that are done after the decision to pass the packet to the host memory was done.

Terminology:

- **Compare** — The field values are compared and must be exactly equal to the value specified in this document.
- **Checked** — The field values are checked for calculation (header length ...).
- **Ignore** — The field values are ignored but the field is counted as part of the header.

### A.2.1 Type 1.1: Ethernet (VLAN/SNAP) IP packets

#### A.2.1.1 Type 1.1: Ethernet, IP, Data

This type contains only Ethernet header and IPv4 header while the payload header of the IP is not IPv6/TCP/UDP.

| Offset             | # of Bytes  | Field                                 | Value                       | Action  | Comment                                                      |

| 46+D+S+N           | 1/2         | Header Length                 |                             | Check   |                                                                     |
| 46.5+D+S+N         | 1.5         | Different bits                | -                           | Ignore  |                                                                     |
| 48+D+S+N           | 2           | Window size                   | -                           | Ignore  |                                                                     |
| 50+D+S+N           | 2           | TCP checksum                  | -                           | Ignore  |                                                                     |
| 52+D+S+N           | 2           | Urgent pointer                | -                           | Ignore  |                                                                     |
| 54+D+S+N           | F           | TCP options                   | -                           | Ignore  |                                                                     |

In this case, the packet is split after (54+D+S+N+F) bytes.

- $N = (\text{IP HDR length} - 5) * 4.$
- $F = (\text{TCP header length} - 5) * 4.$

A.2.1.4      Type 1.4: Ethernet IPv4 IPv6

A.2.1.4.1      IPv6 Header Options Processing

This type of processing looks at the next-header field and header length to determine the identity of the next-header processes, the IPv6 options, and it's length.

If the next header in the IPv6 header is equal to 0x00/0x2B/0x2C/0x3B/0x3c it means that the next header is an IPv6 option header and this is its structure:

Header Len determines the length of the header while the next header field determines the identity of the next header (should be any IPv6 extension header for another IPv6 header option).

A.2.1.4.2      IPv6 Next Header Values

When parsing an IPv6 header, the X550 does not parse all possible extension headers. If there is an extension header that is not supported by the X550, the packet is treated as an unknown payload after the IPv6 header.

| Value | Header Type               |
|-------|---------------------------|
| 0x00  | Hop by Hop                |
| 0x2B  | Routing                   |
| 0x2C  | Fragment                  |
| 0x3B  | No next header (EOL)      |
| 0x3C  | Destination option header |

The next header in a fragment header is ignored and this extension header is expected to be the last header.

**A.2.1.4.3 Type 1.4.1: Ethernet IPv4 IPv6 Data**

This type contains only Ethernet header, IPv4 header, and IPv6 header.

| Offset             | # of Bytes  | Field                            | Value                       | Action  | Comment                                                             |

In this case the packet is split after (82+D+S+N+B) bytes.

$N = (\text{IP HDR length} - 5) * 4.$

### A.2.1.4.5 Type 1.4.3: Ethernet (VLAN/SNAP) IPv4 IPv6 TCP

This type contain only Ethernet header, IPv4 header, IPv6 header and TCP header.

| Offset             | # of Bytes  | Field                            | Value                            | Action  | Comment                                                             |

| 94+T   | F          | TCP options    | -     | Ignore |         |

In this case the packet is split after (94+D+S+N+B+F) bytes.

- $T = D + S + N + B$
- $N = (\text{IP HDR length} - 5) * 4$ .
- $F = (\text{TCP HDR length} - 5) * 4$

## A.2.2 Type 2: Ethernet, IPv6

### A.2.2.1 Type 2.1: Ethernet, IPv6 Data

This type contains only an Ethernet header and an IPv6 header while the packet should be a fragmented packet. If the packet is not fragmented and the Next header is not supported, the header is not split. The supported packet types for header split are programmed in PSRTYPE register (per VF).

| Offset             | # of Bytes  | Field                            | Value                       | Action  | Comment                                                               |
|--------------------|-------------|----------------------------------|-----------------------------|---------|-----------------------------------------------------------------------|
| 0                  | 6           | Destination Address              |                             | Ignore  | MAC Header – Processed by main address filter, or broadcast filter.   |
| 6                  | 6           | Source Address                   |                             | Ignore  |                                                                       |

In this case the packet is split after (54+D+S+N+F) bytes.

- $F = (\text{TCP header length} - 5) * 4$ .
- The last 'next-header' field of the last header of the IP section must be 0x11.

### A.2.3 Type 3: Reserved

Type 3 used to be iSCSI packets (Header split is not supported for iSCSI packets in the X550).

## A.2.4 Type 4: Reserved

## A.2.5 Type 5: Cloud Packets

### A.2.5.1 Type 5.1: Ethernet, IPv4, NVGRE, IPv4/6, TCP/UDP

This type contains an Ethernet header an IPv4 Header, a GRE header an IPv4/6 header and a TCP or UDP header. The supported packet types for header split are programmed in PSRTYPE register (per VF).

| <b>UDP/TCP - as described above</b>       |            |                         |               |         | Split on L4 is done after these fields. |

### A.2.5.2 Type 5.2: Ethernet, IPv4, VXLAN, MAC, IPv4/6, TCP/UDP

This type contains an Ethernet header an IPv4 Header, a UDP header with a specific UDP destination port a VXLAN header, an inner MAC header, an IPv4/6 header and a TCP or UDP header. The supported packet types for header split are programmed in PSRTYPE register (per VF).

| Offset             | # of Bytes  | Field                         | Value                       | Action  | Comment                                                             |
|--------------------|-------------|-------------------------------|-----------------------------|---------|---------------------------------------------------------------------|
| 0                  | 6           | Destination Address           |                             | Ignore  | MAC Header – Processed by main address filter, or broadcast filter. |
| 6                  | 6           | Source Address                |                             | Ignore  |                                                                     |

## A.3 IPsec Formats Run Over the Wire

This section describes the IPsec packet encapsulation formats run over the wire by IPsec packets concerned with the off load in either Tx or Rx direction.

The following legend is valid for [Figure A-12](#) through [Figure A-17](#) of this appendix:

|                                                                                                                                                                                        |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Shaded fields correspond to the portion of the data that is protected by the integrity check.                                                                                          |
| Yellow colored fields are mutable fields that might be changed when traveling between the source and the destination, and are zeroed when computing ICV or when encrypting/decrypting. |
| Cyan colored fields correspond to the portion of data that is protected for both integrity and confidentiality.                                                                        |
| Non-colored fields are not protected either for integrity or for confidentiality.                                                                                                      |

## A.3.1 AH Formats

- IPv4 header:
  - **IP total length** (2 bytes) — Total IP packet length in bytes, including IP header, AH header, TCP/UDP header, and TCP/UDP payload.
  - **Protocol** (1 byte) — AH protocol number, i.e. value 51.
- IPv6 header:
  - **IP payload length** (2 bytes) — IP payload length in bytes, including AH header, TCP/UDP header, and TCP/UDP payload.
  - **Next header** (1 byte) — AH protocol number, i.e. value 51.
- AH header:
  - **Next header** (1 byte) — Layer4 protocol number, 6 for TCP, 17 for UDP, etc.
  - **AH length** (1 byte) — Authentication Header length in 32-bit Dwords units, minus "2", i.e. for AES-128 its value is 7 for IPv4 and 8 for IPv6.
  - **Reserved** (2 bytes) — Must be set to zero.
  - **SPI** (4 bytes) — Arbitrary 32-bit Security Parameters Index allocated by the receiver to identify the SA to which the incoming packet is bound. It is required that the local OS allocates SPIs in a unique manner per local IP Address.
  - **SN** (4 bytes) — Unsigned 32-bit Sequence Number that contains a counter value that increases by one for each Ethernet frame sent. It is initialized to 0 by the sender (and the receiver) when the SA is established, i.e. the first packet sent using a given SA has a sequence number of 1.
  - **IV** (8 bytes) — Initialization Vector to be used 'as is' in the nonce input to AES-128 crypto engine, but it must be zeroed prior to using it in the AAD input to the engine.
  - **ICV** (16 bytes) — Integrity Check Value for this packet, authentication tag output of the AES-128 crypto engine. As being part of the AH header, this field is also included in the AAD input to the crypto engine, and it should be zeroed prior to the computation.
  - **ICV Padding** (4 bytes) — *Explicit* padding bytes appended to the ICV field in IPv6, as it is required to maintain the (Authentication) extension header length as a multiple of 64 bits. By *explicit* we mean that these bytes are sent over the wire. It is formed by 4 arbitrary bytes that need not be random to achieve security. For TSO, it is replicated from the header provided by the driver in every frame.
- L4 header (for example - TCP/UDP) — Length (in bytes) depend on the protocol.
- L4 payload (for example - TCP/UDP) — Can be any length in bytes.

|   | 0   | 3 | 4           | 7 | 8              | 15 | 16    | 18 | 19 | 31                                      |

1. IV field has been colored in Yellow as it must be zeroed in the AAD input to AES-128 crypto engine, in spite of this it is NOT zeroed in the nonce input to the engine.

**Figure A-12. AH Packet Over IPv4**

1. IV field has been colored in Yellow as it must be zeroed in the AAD input to AES-128 crypto engine, in spite of this, it is NOT zeroed in the nonce input to the engine.

**Figure A-13. AH Packet Over IPv6**

## A.3.2 ESP Formats

- IPv4 header:
  - **IP total length** (2 bytes) — Total IP packet length in bytes, including IP header, ESP header, TCP/UDP header, TCP/UDP payload, ESP trailer, and ESP ICV if present.
  - **Protocol** (1 byte) — ESP protocol number, i.e. value 50.
- IPv6 header:
  - **IP payload length** (2 bytes) — IP payload length in bytes, including ESP header, TCP/UDP header, TCP/UDP payload, ESP trailer, and ESP ICV if present.
  - **Next header** (1 byte) — ESP protocol number, i.e. value 50.
- ESP header:
  - **SPI** (4 bytes) — arbitrary 32-bit Security Parameters Index allocated by the receiver to identify the SA to which the incoming packet is bound. It is required that the local OS allocated SPIs in a unique manner per local IP Address.
  - **SN** (4 bytes) — unsigned 32-bit Sequence Number that contains a counter value that increases by one for each Ethernet frame sent. It is initialized to 0 by the sender (and the receiver) when the SA is established, i.e. the first packet sent using a given SA has a sequence number of 1.
  - **IV** (8 bytes) — Initialization Vector to be used in the nonce input field of the AES-128 crypto engine, and for authenticated-only ESP packets it is used also in the AAD input.
- L4 header (for example - TCP/UDP):
  - Length (in bytes) depend on the protocol.
  - TCP/UDP checksum computed from the TCP/UDP header up to the end of TCP payload, excluding ESP trailer.
  - TCP/UDP header is encrypted if ESP encryption is required.
- L4 payload (for example - TCP/UDP)— Can be any length in bytes. It is encrypted if ESP encryption is required.
- ESP trailer:
  - **Padding** (0-255 bytes) — unsigned 1-byte integer values, with its content started by 1 and making up a monotonically increasing sequence: 1, 2, 3,... Though in Tx it is only 0-15 bytes long, in Rx it might be longer, if the sender's policy is to hide the packet length.
  - **Padding length** (1 byte) — Number of *explicit* padding bytes (Padding length and Next header bytes excluded) required to get 4-bytes alignment of the ESP header, TCP/UDP header, TCP/UDP payload, and ESP trailer. By *explicit* we mean that these bytes are sent over the wire. A remote IPsec implementation may also add more padding bytes (up to 255-bytes) than the minimum required for getting the 4-bytes alignment with the aim of hiding the packet length.
  - **Next header** (1 byte) — Layer4 protocol number, 6 for TCP, 17 for UDP, etc.
  - **ESP** trailer is encrypted if ESP encryption is required.
- **ESP ICV** (16 bytes) — Integrity Check Value for this packet, authentication tag output of the AES-128 crypto engine.

Figure A-14. Authenticated Only ESP Packet Over IPv4

Figure A-15. Authenticated & Encrypted ESP Packet Over IPv4

**Figure A-16. Authenticated Only ESP Packet Over IPv6**

**Figure A-17. Authenticated and Encrypted ESP Packet Over IPv6**

For authenticated and encrypted ESP packets, though it is used in the Nonce input to the AES-128 crypto engine, the IV field was left non-colored because it is not a part of the ADD or the Plaintext input fields.

## A.4 FCoE Framing

Related standards:

### A.4.1 FCoE Frame Format

FC over Ethernet packets encapsulate FC frames as shown in [Figure A-18](#) and [Figure A-19](#). Maximum expected FCoE frame size is 2164 bytes. This size does not include FC extension headers (not expected in FCoE), without optional encapsulation (expected to be off-loaded by the hardware) and without CN tag (not expected in receive).

All fields in the FCoE frame are treated as any other field in the network. The MS Byte is first on the wire and the LS bit on each byte is first on the wire. This rule applies for all fields including those ones that span on non complete byte boundaries such as the FCoE VER field.

**Note:**    LSB goes first on the wire.

**Figure A-18. Ethernet Encapsulation to FC frames**

|        | msb<br>31<br>First byte on the wire                                     | lsb<br>24 | msb<br>23                         | lsb<br>16 | msb<br>15                     | lsb<br>12 | msb<br>11 | lsb<br>8 | msb<br>7<br>Last byte on the wire | lsb<br>0 |

| N+8    | EOF                                                                     |           | Reserved                          |           |                               |           |           |          |                                   |          |
| M      | Ethernet CRC                                                            |           |                                   |           |                               |           |           |          |                                   |          |

Figure A-19. FCoE Packet Structure

### A.4.1.1 Ethernet MAC Addresses

L2 destination and Source Ethernet MAC Addresses (each of them is 6 bytes long). The Ethernet MAC Address of the target is assumed to be assigned by the network. It could be done by the FCoE repeater or LAN administrator. The mechanism that is used for Ethernet MAC Address assignment and Ethernet MAC Address detection is outside of the scope of this document.

### A.4.1.2 802.1Q Tag

802.1Q tagging is mandatory for FCoE usage. FCoE assumes DCB functionality which provides Priority-based FC and QCN. These functions require 802.1Q tag presence to define packet priority.

### A.4.1.3 FCoE Header

The FCoE header is composed of a new FCoE Ethernet type, FCoE version tag and the Start Of Frame tag.

- **FCoE Ethernet Type** — Equals 0x8906
- **Version (Ver)** — A 4-bit field that indicates the FCoE protocol version number. The X550 supports FCoE version as defined by FCRXCTRL.FCOEVER.
- **Start of Frame (SOF)** — The FCoE Start of frame is a subset of the FC-FS-2 SOF codes as defined in the [Table A-1](#).

**Table A-1. E\_SOF Mapping**

| FC SOF | FCoE SOF Code | FC Traffic Class | Comment                                         |
|--------|---------------|------------------|-------------------------------------------------|
| SOFf   | 0x28          | F                | Fabric start of frame. Not expected in an FCoE. |
| SOFi2  | 0x2D          | 2                | Used in the first frames in a sequence.         |
| SOFn2  | 0x35          | 2                | Used in all but first frame in a sequence.      |
| SOFi3  | 0x2E          | 3                | Used in the first frames in a sequence.         |
| SOFn3  | 0x36          | 3                | Used in all but first frame in a sequence.      |

### A.4.1.4 FCoE Packet Encapsulation Trailer

The FCoE trailer is composed of an End of frame, optional padding and Ethernet CRC.

- **End of Frame (EOF)** — The FCoE End of frame maps the FC-FS-2 EOF codes as defined in the [Table A-2](#).
- **Ethernet Padding** — The minimal FC frame length could be as small as 28 bytes long (FC header with no data). In such a case, the encapsulated FC frame must include padding so that the total Ethernet packet size is not smaller than 64 bytes.
- **Ethernet CRC** — The IEEE 802.3 CRC as defined by the following polynomial:

$$X_{32}+X_{26}+X_{23}+X_{22}+X_{16}+X_{12}+X_{11}+X_{10}+X_8+X_7+X_5+X_4+X_2+X+1$$

**Table A-2. EOF Mapping**

| FC EOF | FCoE EOF Code | FC Traffic Class | Comment                                                   |
|--------|---------------|------------------|-----------------------------------------------------------|
| EOFn   | 0x41          | 2, 3, 4, F       | Normal EOF.                                               |
| EOFt   | 0x42          | 2, 3, 4, F       | EOF Terminate used to close a sequence.                   |
| EOFni  | 0x49          | 2, 3, 4, F       | EOF Invalid indicating that the frame content is invalid. |
| EOFa   | 0x50          | 2, 3, 4, F       | EOF Abort.                                                |

## A.4.2 FC Frame Format

**Note:** This section is provided as a background on FC and is not required for the hardware implementation. For a complete description of the FC fields please refer to FC-FS-2 specification.

The FC frame as defined in FC-FS-2 specification is shown in the [Figure A-20](#) below while relevant fields are detailed in this section.

|     |                 |           |                  |                                         |        |     |
|-----|-----------------|-----------|------------------|-----------------------------------------|--------|-----|
| SOF | Extended Header | FC Header | Optional Headers | FC Payload (FC Data & optional padding) | FC CRC | EOF |
|-----|-----------------|-----------|------------------|-----------------------------------------|--------|-----|

**Figure A-20. FC Frame Format**

### A.4.2.1 FC SOF and EOF

FC Start of frame (SOF) delimiter and End of frame (EOF) delimiter. In FCoE frames, the SOF and EOF fields in the FC frame are extracted and reflected in the FCoE encapsulation. The SOF and EOF codes that are reflected in the FCoE framing are shown in [Table A-1](#) and [Table A-2](#).

### A.4.2.2 FC CRC

The Cyclic Redundancy Check (CRC) is a four byte field that follows the Data Field. It enables end to end integrity checking on the whole FC frame. The hardware adds this field if the *FCoE* bit is set in the transmit context descriptor. The FC CRC off load is described in more detail in [Section 7.11.3.2](#).

### A.4.2.3 FC Header

The FC header fields are provided in the header buffer by the FCoE driver. The FC header includes fields that are modified by the hardware as part of Large Send off load. These fields are indicated in this section as “**Dynamic**” while fields that are not modified by the hardware are indicated as “**Static**”.

#### Routing Control (R\_CTL)

The R\_CTL is a one-byte **Static** field that contains routing and information bits to categorize the frame function.

#### Class Specific Control (CS\_CTL)

This is a 1 byte **Static** field that defines either the Class specific control or priority according to bit 17 in the Frame control (F\_CTL) field.

#### Destination Identification (D\_ID)

The D\_ID is a 3 byte **Static** field that defines the FC destination address.

#### Source Identification (S\_ID)

The S\_ID is a 3 byte **Static** field that defines the FC source address.

#### Data Structure Type (TYPE)

The TYPE is a 1 byte **Static** field that identifies the protocol of the frame content for data frames.

### Frame Control (F\_CTL)

The F\_CTL is a 3 byte **Dynamic** field that contains control information relating to the frame content. The F\_CTL is further described in [Section A.4.2.3.1](#). [Section 7.11.2.7](#) describes how the F\_CTL field is modified during large send.

### Data Field Control (DF\_CTL)

The DF\_CTL is a 1 byte **Dynamic** field that specifies the presence of optional headers at the beginning of the Data\_Field. The Optional headers supported by large send are present only on the first frame in the FC sequence. [Section 7.11.2.7.1](#) describes how the DF\_CTL field is modified during large send.

### Sequence ID (SEQ\_ID)

The SEQ\_ID is a 1 byte **Static** number associated with a sequence. A sender must assign SEQ\_ID numbers so that the recipient would always be able to distinguish between consecutive sequences. SEQ\_ID do not have to be sequential and do not have to be unique even within the same IO exchange as long as it is guaranteed that the recipient would be able to distinguish between them.

### Sequence Count (SEQ\_CNT)

The SEQ\_CNT is a 2 byte **Dynamic** field that indicates the sequential order of Data frame transmission within a single Sequence or multiple consecutive Sequences for the same Exchange. The SEQ\_CNT of the first Data frame of the first Sequence of the Exchange transmitted by either the Originator or Responder is '0'. The SEQ\_CNT of subsequent Data frames in the Sequence is increased by one for each data frame. The SEQ\_CNT of the first Data frame in each sequence other than the first one can start at '0' or be increased by 1 from the last used SEQ\_CNT.

### Originator Exchange ID (OX\_ID)

The OX\_ID is a two-byte **Static** field that identifies the Exchange\_ID assigned by the Originator. If the Originator is enforcing uniqueness via the OX\_ID mechanism, it must set a unique value for OX\_ID other than FFFFh. A value of FFFFh indicates that the OX\_ID is unassigned and that the Originator is not enforcing uniqueness via the OX\_ID. The X550 supports large receive and direct data placement only if OX\_ID is used to identify uniqueness.

### Responder Exchange ID (RX\_ID)

The RX\_ID is a two byte **Static** field assigned by the Responder that must provide a unique, locally meaningful exchange identifier at the Responder. The Responder of the Exchange must set a unique value for RX\_ID other than FFFFh.

### Parameter (PARAM)

The Parameter field is a **Dynamic** field which is based on frame type. For Data frames with the relative offset present bit set to 1, the Parameter field specifies relative offset. The offset defines the relative displacement of the first byte of the Payload of the frame from the base address as specified by the ULP. Relative offset is expressed in terms of bytes.

#### A.4.2.3.1 Frame Control (F\_CTL)

The Frame Control (F\_CTL) is a three-byte field that contains control information relating to the frame content. If an error in bit usage is detected, the software initiates a reject frame (P\_RJT) in response with an appropriate reason code (FCoE software driver responsibility). The F\_CTL format is shown in [Table A-3](#) below.

When a bit(s) is designated as “**Static**” it is provided by the FCoE driver as part of the large send header. The hardware keeps this bit(s) as is in all preceding frames of the large send.

When a bit(s) is designated as “**Dynamic**” it is provided by the FCoE driver as part of the large send header. The hardware may change it in some of the packets in the large send as described in [Section 7.11.2.7](#). Exact setting of these bit(s) is described in the [Table A-3](#) below.

When a bit(s) is designated as meaningful under a set of conditions, that bit must be ignored if those conditions are not present.

**Table A-3. F\_CTL Format**

| Control Field            | Bit(s) | Type    | Description                                                                                                                                                                                                                                                                                                                        |
|--------------------------|--------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Exchange Context         | 23     | Static  | 0b = Originator of exchange.<br>1b = Responder of exchange.                                                                                                                                                                                                                                                                        |
| Sequence Context         | 22     | Static  | 0b = Sequence initiator.<br>1b = Sequence recipient.                                                                                                                                                                                                                                                                               |
| First Sequence           | 21     | Static  | 0b = Sequence other than first of exchange.<br>1b = first Sequence of exchange.                                                                                                                                                                                                                                                    |
| Last Sequence            | 20     | Static  | 0b = Sequence other than last of exchange.<br>1b = last sequence of exchange must be set on the last data frame of the last sequence. However it can be set on any preceding frames. Once it is set, it must be set on all frames till the last one of that exchange.                                                              |
| End Sequence             | 19     | Dynamic | 0b = Data frame other than last of sequence.<br>1b = last Data frame of sequence.                                                                                                                                                                                                                                                  |
| End Connection           | 18     | Static  | Relevant for Class 1 or 6.                                                                                                                                                                                                                                                                                                         |
| CS CTL / Priority Enable | 17     | Static  | Defines the meaning of the CS_CTL byte in the FC header to be either CS_CTL or Priority indication.<br>0b = Word 1, Bits 31-24 = CS_CTL<br>1b = Word 1, Bits 31-24 = Priority                                                                                                                                                      |
| Sequence Initiative      | 16     | Dynamic | This bit is used to transfer initiative from a sender to a recipient. This bit is meaningful only on the last frame of a sequence (when bit 19 - “End Sequence” is set).<br>0b = Hold sequence initiative.<br>1b = Transfer sequence initiative.                                                                                   |
| X_ID reassigned          | 15     | Static  | Obsolete.                                                                                                                                                                                                                                                                                                                          |
| Invalidate X_ID          | 14     | Static  | Obsolete.                                                                                                                                                                                                                                                                                                                          |
| ACK Form                 | 13:12  | Static  | ACK Form is meaningful on all Class 1, Class 2, or Class 6 Data frames of a Sequence and on all connect request frames. ACK_Form is not meaningful on Class 1, Class 2, or Class 6 Link_Control frames, or any Class 3 frames.<br>00b = No assistance provided<br>01b = Ack_1 Required<br>10b = reserved.<br>11b = Ack_0 Required. |
| Data Compression         | 11     | Static  | Obsolete.                                                                                                                                                                                                                                                                                                                          |
| Data Encryption          | 10     | Static  | Obsolete.                                                                                                                                                                                                                                                                                                                          |
| Retransmitted Sequence   | 9      | Static  | Meaningful in Class 1 and 6 and only.<br>0b = Original sequence transmission.<br>1b = sequence retransmission.                                                                                                                                                                                                                     |

Table A-3. F\_CTL Format (Continued)

| Control Field               | Bit(s) | Type    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------|--------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Unidirectional Transmit     | 8      | Static  | Relevant for Class 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Continue Sequence Condition | 7:6    | Dynamic | Last Data frame - Sequence Initiator<br>00b = No information.<br>01b = Sequence to follow-immediately.<br>10b = Sequence to follow-soon.<br>11b = Sequence to follow-delayed.<br>It is meaningful only when the "End Sequence" is set to '1' and the <i>Sequence Initiative</i> bit is cleared '0'.                                                                                                                                                                                                                                                                                                                        |

| Relative offset present     | 3      | Static  | 0b = Parameter field defined for some frames<br>1b = Parameter Field = relative offset                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Exchange reassembly         | 2      | Static  | Reserved for exchange reassembly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Fill Bytes                  | 1:0    | Dynamic | Defines the number of FC padding bytes to fill in the last frame in the sequence. The value of these bytes is 0x00.<br>When FCoE offload is enabled (TUCMD.FCoE bit is set in the transmit context descriptor), the hardware can pad the FC payload according to the buffer size indicated by software (by the <i>PAYLEN</i> field in the transmit data descriptor).                                                                                                                                                                                                                                                       |

#### A.4.2.4 FC Extended Headers

**Note:** The following section is provided as a background on FC and is not required for the hardware implementation or the software implementation since in FCoE frames, extended headers are not expected. The following quote is from the FCoE specification Rev 0.7 "No Extended Headers are relevant for the operations of a Reedtown NIC".

The diagrams in Figure A-21, Figure A-22 and Table A-4 show the Fibre Channel frame structure with Extended headers and lists the existing headers. Extended headers are identified by the R\_CTL value as shown in the diagrams below. The LAN controller does not support these Extended headers since they are not expected in FCoE usage.

Figure A-21. FC Frame format with Extended Headers

Figure A-22. Extended Header Format

|      |                                 |       |
|------|---------------------------------|-------|
| 0    | Extended Header Specific Fields | R_CTL |
| 4... |                                 |       |

**Figure A-22. Extended Header Format****Table A-4. FC Extended Headers**

| R_CTL       | Extended Header                            | Length   |
|-------------|--------------------------------------------|----------|
| 0x50        | VFT_Header (Virtual Fabric Tagging Header) | 8 Bytes  |
| 0x51        | IFR_Header (Inter-Fabric Routing Header)   | 8 Bytes  |
| 0x52        | Enc_Header (Encapsulation Header)          | 24 Bytes |
| 0x53...0x5F | Reserved                                   | -        |

### A.4.2.5 FC Optional Headers

**Note:** Most of the following section is provided as a background on FC and is not required for the hardware implementation. The reader may skip the detailed explanation of the Optional headers provided below and concentrate in the tables and figures that follow the text.

FCoE frames may include FC Optional headers. These headers (if they exist) would always show in the first frame in a sequence. While FC implementation may include the FC Optional headers only on the first frame in a sequence. In Large send functionality, the FC Optional headers may show only on the first frame as shown in [Figure 7-46](#) and [Table A-5](#) (in [Section 7.11.2.7.1](#)).

The following diagrams [Table A-5](#), [Figure A-23](#) and [Figure A-24](#) show the Fibre Channel frame structure with Optional headers and lists the Optional headers. The Optional headers (that are present) are always ordered as shown in [Figure A-23](#) and [Figure A-24](#). Their presence is indicated in the Data Field Control (DF\_CTL) field in the FC Header as indicated in [Table A-5](#)

Maximum FC frame size: The sum of the length in bytes of the FC Payload, the number of fill bytes, and the lengths in bytes of all optional headers must not exceed 2112.

**Table A-5. FC Optional Headers**

| DF_CTL   | Optional Header          | Length                 |
|----------|--------------------------|------------------------|
| bit 6    | ESP Header / ESP Trailer | Variable               |
| bit 5    | Network Header           | 16 Bytes               |
| bit 4    | Association Header       | 32 Byte                |
| bits 1:0 | Device Header            | 0, 16, 32, or 64 Bytes |

**Figure A-23. FC Frame Format with Optional Headers (without ESP Header)****Figure A-24. FC Frame Format with Optional Headers (with ESP Header)**

## ESP Header

This is the first Optional header which covers the whole FC frame other than the FC header which is transmitted on the clear (as plain text). When an ESP header is present there is also the ESP trailer. If required, the software is responsible for the cryptic calculation and preparing the ESP header and trailer. Its presence is indicated by bit 6 in the DF\_CTL field being set to one. The hardware does not support Large Send off load when ESP Optional header is used. When present, the ESP header and trailer are present in all frames of the exchange.

## Network Header

The Network Header, if used, must be present only in the first Data frame of a Sequence. A bridge or a gateway node that interfaces to an external Network may use the Network Header. The Network Header, is an optional header 16 Bytes long within the FC Data Field content. Its presence is indicated by bit 5 in the DF\_CTL field being set to one. The Network Header may be used for routing between Fibre Channel networks of different Fabric address spaces, or Fibre Channel and non-Fibre Channel networks. The Network Header contains Name Identifiers for Network Destination Address and Network Source Address.

## Association Header

The Association Header, if used, must be present only in the first Data frame of a Sequence. The Association Header is an optional header 32 Bytes long within the Data Field content. Its presence is indicated by bit 4 in the DF\_CTL field being set to one. The Association Header may be used to identify a specific Process or group of Processes within a node associated with an Exchange. When an Nx\_Port has indicated during Login that an Initial Process Associator is required to communicate with it, the Association Header should be used by that Nx\_Port to identify a specific Process or group of Processes within a node associated with an Exchange. The X550 does not use the Association for any filtering purposes but rather uses the OX\_ID.

## Device Header

The Device Header, if present, must be present either in the first Data frame or in all Data frames of a Sequence. If Large Send off load is used, the Device header, if present, is present only in the first frame of the same large send. The Device Header, if present, must be 16, 32, or 64 bytes in size as defined by bits 1:0 in the DF\_CTL field. The contents of the Device Header are controlled at a level above FC-2. Upper layer protocol (ULP) may use a Device Header, requiring the Device Header to be supported. The Device Header may be ignored and skipped, if not needed. If a Device Header is present for a ULP that does not require it, the related FC-4 may reject the frame with the reason code of "TYPE not supported".

## A.5 E-tag and S-tag Formats

**Note:** S-tags are not supported in the X550.

Packets with S-tag has the following format:

The S-tag format is the format defined for S-tags in the IEEE 802.1ad specification as described below:

**Figure A-25. S-tag Format**

Packets with E-tag has the following format:

The E-tag format is the format defined in the IEEE 802.1BR specification as described below:

### Figure A-26. E-tag Format

The Ingress\_E-CID\_ext and E-CID\_ext are always zero for endpoints and are effectively reserved.
