### General Description

The HV76 is a low-voltage serial to high-voltage parallel converter with push-pull outputs. This device has been designed for use as a driver for color AC plasma displays.

The device has 4 parallel 8-bit shift registers permitting data rate 4 times the speed of one. The data are clocked in simultaneously on all four data inputs with a single clock. Data are shifted in on a low to high transition of the clock. The latches and control logic perform the output enable function.

The DIR pin causes clockwise (CW) shifting of the data when connected to  $V_{DD1}$ , and counterclockwise (CCW) shifting when connected to GND. Operation of the shift register is not affected by the  $\overline{LE}$  (latch enable) input. Transfer of data from the shift registers to the latches occurs when the  $\overline{LE}$  input is high. Data is stored in the latches when  $\overline{LE}$  is low. The current source on the logic inputs provides active pull up when the input pins are open.
