

1428 MHz Dual Output LVPECL Clock Synthesizer

The MPC92433 is a 3.3 V compatible, PLL based clock synthesizer targeted for high performance clock generation in mid-range to high-performance telecom, networking, and computing applications. With output frequencies from 42.50 MHz to 1428 MHz and the support of two differential PECL output signals, the device meets the needs of the most demanding clock applications.

Features

- 42.50 MHz to 1428 MHz synthesized clock output signal
- Two differential, LVPECL-compatible high-frequency outputs
- Output frequency programmable through 2-wire I²C bus or parallel interface
- On-chip crystal oscillator for reference frequency generation
- Alternative LVCMOS compatible reference clock input
- Synchronous clock stop functionality for both outputs
- LOCK indicator output (LVCMOS)
- LVCMOS compatible control inputs
- Fully integrated PLL
- 3.3 V power supply
- 48-lead LQFP
- 48-lead Pb-free package available
- SiGe Technology
- Ambient temperature range: -40°C to +85°C

Typical Applications

- Programmable clock source for server, computing, and telecommunication systems
- Frequency margining
- Oscillator replacement

The MPC92433 is a programmable high-frequency clock source (clock synthesizer). The internal PLL generates a high-frequency output signal based on a low-frequency reference signal. The frequency of the output signal is programmable and can be changed on the fly for frequency margining purposes.

The internal crystal oscillator uses the external quartz crystal as the basis of its frequency reference. Alternatively, a LVCMOS compatible clock signal can be used as a PLL reference signal. The frequency of the internal crystal oscillator is divided by a selectable divider and then multiplied by the PLL. The VCO within the PLL operates over a range of 1360 to 2856 MHz. Its output is scaled by a divider that is configured by either the I²C or parallel interfaces. The crystal oscillator frequency f_{TAL}, the PLL pre-divider P, the feedback-divider M, and the PLL post-divider N determine the output frequency. The feedback path of the PLL is internal.

The PLL post-divider N is configured through either the I²C or the parallel interfaces, and can provide one of seven division ratios (2, 4, 6, 8, 12, 16, 32). This divider extends the performance of the part while providing a 50 Ω duty cycle. The high-frequency outputs, Q_A and Q_B, are differential and are capable of driving a pair of transmission lines terminated 50 Ω to V_{CC} - 2.0 V. The second high-frequency output, Q_B, can be configured to run at either 1x or 1/2x of the clock frequency or the first output (Q_A). The positive supply voltage for the internal PLL is separated from the power supply for the core logic and output drivers to minimize noise induced jitter.

The configuration logic has two sections: I²C and parallel. The parallel interface uses the values at the M[9:0], NA[2:0], NB, and P parallel inputs to configure the internal PLL dividers. The parallel programming interface has priority over the serial I²C interface. The serial interface is I²C compatible and provides read and write access to the internal PLL configuration registers. The lock state of the PLL is indicated by the LVCMOS-compatible LOCK output.

1. AC specifications are subject to change.

2. AC characteristics apply for parallel output termination of $50\ \Omega$ to V_{TT} .

3. The input frequency f_{XTAL} , the PLL divider M and P must match the VCO frequency range: $f_{VCO} = f_{XTAL} \cdot M \div P$. The feedback divider M is limited to $170 \leq M \leq 357$ (for P=2) and $340 \leq M \leq 714$ (for P=4) for stable PLL operation.

4. Output frequency for Q_A, Q_B if N_B=0. With N_B=1 the Q_B output frequency is half of the Q_A output frequency.

5. Maximum cycle jitter measured at the lowest VCO frequency. Refer to Figure 8 for the cycle jitter vs. frequency characteristics.

6. Maximum period jitter measured at the lowest VCO frequency. Refer to Figure 9 for the period jitter vs. frequency characteristics.

7. See the [LOCK Detect](#) section on page 13.

Output Frequency Configuration

The MPC92433 is a programmable frequency source (synthesizer) and supports an output frequency range of 42.5 – 1428 MHz. The output frequency f_{OUT} is a function of the reference frequency f_{REF} and the three internal PLL dividers P, M, and N. f_{OUT} can be represented by this formula:

$$f_{OUT} = (f_{REF} \div P) \cdot M \div (N_A \cdot B) \quad (1)$$

The M, N and P dividers require a configuration by the user to achieve the desired output frequency. The output divider, N_A , determines the achievable output frequency range (see [Table 7](#)). The PLL feedback-divider M is the frequency multiplication factor and the main variable for frequency synthesis. For a given reference frequency f_{REF} , the PLL feedback-divider M must be configured to match the specified VCO frequency range in order to achieve a valid PLL configuration:

$$f_{VCO} = (f_{REF} \div P) \cdot M \text{ and} \quad (2)$$

$$1360 \leq f_{VCO} \leq 2856 \quad (3)$$

The output frequency may be changed at any time by changing the value of the PLL feedback divider M. The smallest possible output frequency change is the synthesizer granularity G (difference in f_{OUT} when incrementing or decrementing M). At a given reference frequency, G is a function of the PLL pre-divider P and post-divider N:

$$G = f_{REF} \div (P \cdot N_{A,B}) \quad (4)$$

The N_B divider configuration determines if the output Q_B generates a 1:1 or 2:1 frequency copy of the Q_A output signal. The purpose of the PLL pre-divider P is to situated the PLL into the specified VCO frequency range f_{VCO} (in combination with M). For a given output frequency, $P = 4$ results in a smaller output frequency granularity G, $P = 2$ results a larger output frequency granularity G and also increases the PLL bandwidth compared to the $P = 2$ setting.

The following example illustrates the output frequency range of the MPC92433 using a 16-MHz reference frequency.

Table 7. Frequency Ranges ($f_{REF}=16$ MHz)

$f_{OUT} (Q_A)$ [MHz]	N_A	M	P	G [MHz]
680–1428	$N_A=2$	170-357	2	4
		340-714	4	2
340–714	$N_A=4$	170-357	2	2
		340-714	4	1
226.67–476	$N_A=6$	170-357	2	1.33
		340-714	4	0.66
170–357	$N_A=8$	170-357	2	1
		340-714	4	0.5
113.33–238	$N_A=12$	170-357	2	0.66
		340-714	4	0.33
85–178.5	$N_A=16$	170-357	2	0.5
		340-714	4	0.25
42.5–89.25	$N_A=32$	170-357	2	0.25
		340-714	4	0.125

Example Output Frequency Configuration

If a reference frequency of 16 MHz is available, an output frequency at Q_A of 250 MHz and a small frequency granularity is desired, the following steps would be taken to identify the appropriate P, M, and N configuration:

- Use [Table 7](#) to select the output divider, N_A , that matches the desired output frequency or frequency range. According to [Table 7](#), a target output frequency of 250 MHz falls in the f_{OUT} range of 170 to 357 MHz and requires to set $N_A = 8$
- Calculate the VCO frequency $f_{VCO} = f_{OUT} \cdot N_A$, which is 2000 MHz in this example.
- Determine the PLL feedback divider: $M = f_{VCO} \div P$. The smallest possible output granularity in this example calculation is 500 kHz (set $P = 4$). M calculates to a value of $2000 \div 4 = 500$.
- Configure the MPC92433 with the obtained settings:
 - $M[9:0] = 0111110100b$ (binary number for $M=500$)
 - $N_A[2:0] = 010$ ($\div 8$ divider, see [Table 9](#))
 - $P = 1$ ($\div 4$ divider, see [Table 8](#))
 - $N_B = 0$ ($f_{OUT, QB} = f_{OUT, QA}$)
- Use either parallel or serial interface to apply the setting. The I²C configuration bytes for this example are:
 - PLL_H=01010010b and PLL_L=11110100b.
 See [Table 13](#) and [Table 14](#) for register maps.

PLL Divider Configuration

Programming the MPC92433

The MPC92433 has a parallel and a serial configuration interface. The purpose of the parallel interface is to directly configure the PLL dividers through hardware pins without the overhead of a serial protocol. At device startup, the device always obtains an initial PLL frequency configuration through the parallel interface. The parallel interface does not support reading the PLL configuration.

The serial interface is I²C compatible. It allows reading and writing devices settings by accessing internal device registers. The serial interface is designed for host-controller access to the synthesizer frequency settings for instance in frequency-margining applications.

Using the Parallel Interface

The parallel interface supports write-access to the PLL frequency setting directly through 15 configuration pins (P, M[9:0], NA[2:0], and NB). The parallel interface must be enabled by setting PLOAD to logic low level. During PLOAD = 0, any change of the logical state of the P, M[9:0], NA[2:0], and NB pins will immediately affect the internal PLL divider settings, resulting in a change of the internal VCO-frequency and the output frequency. The parallel interface mode disables the I²C write-access to the internal registers; however, I²C read-access to the internal configuration registers is enabled.

Upon startup, when the device reset signal is released (rising edge of the MR signal), the device reads its startup configuration through the parallel interface and independent on the state of PLOAD. It is recommended to provide a valid PLL configuration for startup. If the parallel interface pins are left open, a default PLL configuration will be loaded. After the low-to-high transition of PLOAD, the configuration pins have no more effect and the configuration registers are made accessible through the serial interface.

Table 10. Feedback Divider Configuration

Feedback Divider M	9	8	7	6	5	4	3	2	1	0
Pin	M9	M8	M7	M6	M5	M4	M3	M2	M1	M0
Default	0	1	1	1	1	1	0	1	0	0

Table 11. PLL Pre/Post Divider Configuration (N, P)

Post-D. NA	2	1	0	Post-D. NB	NB	Pre-D. P	P
Pin	NA2	NA1	NA0	Pin	NB	Pin	P
Default	0	1	0	Default	0	Default	1

Using the I²C Interface

PLOAD = 1 enables the programming and monitoring of the internal registers through the I²C interface. Device register access (write and read) is possible through the 2-wire interface using SDA (configuration data) and SCL (configuration clock) signals. The MPC92433 acts as a slave device at the I²C bus. For further information on I²C it is recommended to refer to the I²C bus specification (version 2.1).

PLOAD = 0 disables the I²C-write-access to the configuration registers and any data written into the register is ignored. However, the MPC92433 is still visible at the I²C interface and I²C transfers are acknowledged by the device. Read-access to the internal registers during PLOAD = 0 (parallel programming mode) is supported.

Note that the device automatically obtains a configuration using the parallel interface upon the release of the device reset (rising edge of MR) and independent on the state of PLOAD. Changing the state of the PLOAD input is not supported when the device performs any transactions on the I²C interface.

Programming Model and Register Set

The synthesizer contains two fully accessible configuration registers (PLL_L and PLL_H) and a write-only command register (CMD). Programming the synthesizer frequency through the I²C interface requires two steps: 1) writing a valid PLL configuration to the configuration registers and 2) loading the registers into the PLL by an I²C command. The PLL frequency is affected as a result of the second step.

This two-step procedure can be performed by a single I²C transaction or by multiple, independent I²C transactions. An alternative way to achieve small PLL frequency changes is to use the increment or decrement commands of the

synthesizer, which have an immediate effect on the PLL frequency.

Figure 3. I²C Mode Register Set

Figure 3 illustrates the synthesizer register set. PLL_L and PLL_H store a PLL configuration and are fully accessible (Read/Write) by the I²C bus. CMD (Write only) accepts commands (LOAD, GET, INC, DEC) to update registers and for direct PLL frequency changes.

Set the synthesizer frequency:

- 1) Write the PLL_L and PLL_H registers with a new configuration (see Table 13 and Table 14 for register maps)
- 2) Write the LOAD command to update the PLL dividers by the current PLL_L, PLL_H content.

Read the synthesizer frequency:

- 1) Write the GET commands to update the PLL_L, PLL_H registers by the PLL divider setting
- 2) Read the PLL_L, PLL_H registers through I²C

Change the synthesizer frequency in small steps:

- 1) Write the INC or DEC command to change the PLL frequency immediately. Repeat at any time if desired.

LOAD and GET are inverse command to each other. LOAD updates the PLL dividers and GET updates the configuration registers. A fast and convenient way to change the PLL frequency is to use the INC (increment M) and DEC (decrement M) commands of the synthesizer. INC (DEC) directly increments (decrements) the PLL-feedback divider M and immediately changes the PLL frequency by the smallest step G (see Table 7 for the frequency granularity G). The INC and DEC commands are designed for multiple and rapid PLL frequency changes as required in frequency margining applications. INC and DEC do not require the user to update the PLL dividers by the LOAD command, INC and DEC do not update the PLL_L and PLL_H registers either (use LOAD for an initial PLL divider setting and, if desired, use GET to read the PLL configuration). Note that the synthesizer does not check any boundary conditions such as the VCO frequency range. Applying the INC and DEC commands could result in invalid VCO frequencies (VCO frequency beyond lock range).

Register Maps

Table 12. Configuration Registers

Address	Name	Content	Access
0x00	PLL_L	Least significant 8 bits of M	R/W
0x01	PLL_H	Most significant 2 bits of M, P, N _A , N _B , and lock state	R/W
0xF0	CMD	Command register (write only)	W only

Register 0x00 (PLL_L) contains the least significant bits of the PLL feedback divider M.

Table 13. PLL_L (0x00, R/W) Register

Bit	7	6	5	4	3	2	1	0
Name	M7	M6	M5	M4	M3	M2	M1	M0

Register content:

M[7:0] PLL feedback-divider M, bits 7–0

Register 0x01 (PLL_H) contains the two most significant bits of the PLL feedback divider M, four bits to control the PLL post-dividers N and the PLL pre-divider P. The bit 0 in PLL_H register indicates the lock condition of the PLL and is set by the synthesizer automatically. The LOCK state is a copy of the PLL lock signal output (LOCK). A write-access to LOCK has no effect.

Table 14. PLL_H (0x01, R/W) Register

Bit	7	6	5	4	3	2	1	0
Name	M9	M8	NA2	NA1	NA0	NB	P	LOCK

Register content:

M[9:8] PLL feedback-divider M, bits 9–8

NA[2:0] PLL post-divider N_A, see Table 9

NB PLL post-divider N_B, see Table 9

P PLL pre-divider P, see Table 8

LOCK Copy of LOCK output signal (read-only)

Note that the LOAD command is required to update the PLL dividers by the content of both PLL_L and PLL_H registers.

Register 0xF0 (CMD) is a write-only command register. The purpose of CMD is to provide a fast way to increase or decrease the PLL frequency and to update the registers. The register accepts four commands, INC (increment M), DEC (decrement M), LOAD and GET (update registers). It is recommended to write the INC, DEC commands only after a valid PLL configuration is achieved. INC and DEC only affect the M-divider of the PLL (PLL feedback). Applying INC and DEC commands can result in a PLL configuration beyond the specified lock range and the PLL may lose lock. The MPC92433 does not verify the validity of any commands such as LOAD, INC, and DEC. The INC and DEC commands change the PLL feedback divider without updating PLL_L and PLL_H.

Table 15. CMD (0xF0): PLL Command (Write-Only)

Command	Op-Code	Description
INC	xxxx0001b (0x01)	Increase internal PLL frequency M:=M+1
DEC	xxxx0010b (0x02)	Decrease internal PLL frequency M:=M-1
LOAD	xxxx0100b (0x04)	Update the PLL divider config. PLL divider M, N, P:=PLL_L, PLL_H
GET	xxxx1000b (0x08)	Update the configuration registers PLL_L, PLL_H:=PLL divider M, N, P

I²C — Register Access in Parallel Mode

The MPC92433 supports the configuration of the synthesizer through the parallel interface (PLOAD = 0) and serial interface (PLOAD = 1). Register contents and the divider configurations are not changed when the user switches from parallel mode to serial mode. However, when switching from serial mode to parallel mode, the PLL dividers immediately reflect the logical state of the hardware pins M[9:0], NA[2:0], NB, and P.

Applications using the parallel interface to obtain a PLL configuration can use the serial interface to verify the divider settings. In parallel mode (PLOAD = 0), the MPC92433 allows read-access to PLL_L and PLL_H through I²C (if PLOAD = 0, the current PLL configuration is stored in PLL_L, PLL_H. The GET command is not necessary and also not supported in parallel mode). After changing from parallel to serial mode (PLOAD = 1), the last PLL configuration is still stored in PLL_L, PLL_H. The user now has full write and read access to both configuration registers through the I²C bus and can change the configuration at any time.

Table 16. PLL Configuration in Parallel and Serial Modes

PLL Configuration	Parallel	Serial (Registers PLL_L, PLL_H)
M[9:0]	Set pins M9–M0	M[9:0] (R/W)
NA[2:0]	Set pins NA2...NA0	NA[2:0] (R/W)
NB	Set pin NB	NB (R/W)
P	Set pin P	P (R/W)
LOCK status	LOCK pin 26	LOCK (Read only)

Programming the I²C Interface

Table 17. I²C Slave Address

Bit	7	6	5	4	3	2	1	0
Value	1	0	1	1	0	Pin ADR1	Pin ADR0	R/W

The 7-bit I²C slave address of the MPC92433 synthesizer is a combination of a 5-bit fixed addresses and two variable bits which are set by the hardware pins ADR[1:0]. Bit 0 of the MPC92433 slave address is used by the bus controller to select either the read or write mode. '0' indicates a transmission (I²C-WRITE) to the MPC92433. '1' indicates a request for data (I²C-READ) from the synthesizer. The hardware pins ADR1 and ADR0 and should be individually set by the user to avoid address conflicts of multiple MPC92433 devices on the same I²C bus.

Write Mode (R/W = 0)

The configuration registers are written by the bus controller by the initiation of a write transfer with the MPC92433 slave address (first byte), followed by the address of the configuration register (second byte: 0x00, 0x01 or 0xF0), and the configuration data byte (third byte). This transfer may be followed by writing more registers by sending the configuration register address followed by one data byte. Each byte sent by the bus controller is acknowledged by the MPC92433. The transfer ends by a stop bit sent by the bus controller. The number of configuration data bytes and the write sequence are not restricted.

Table 18. Complete Configuration Register Write Transfer

1 bit	7 bits	1 bit	1 bit	8 bits	1 bit	8 bits	1 bit	8 bits	1 bit	8 bits	1 bit	1 bit
Start	Slave address	R/W	ACK	&PLL_H	ACK	Config-Byte 1	ACK	&PLL_L	ACK	Config-Byte 2	ACK	Stop
	10110xx ⁽¹⁾	0		0x01		Data		0x00		Data		
Master	Master	Mast	Slave	Master	Slave	Master	Slave	Master	Slave	Master	Slave	Mast

1. xx = state of ADR1, ADR0 pins

Read Mode (R/W = 1)

The configuration registers are read by the bus controller by the initiation of a read transfer. The MPC92433 supports read transfers immediately after the first byte without a change in the transfer direction. Immediately after the bus controller sends the slave address, the MPC92433 acknowledges and then sends both configuration register PLL_L and PLL_H (back-to-back) to the bus controller. The CMD register cannot be read. In order to read the two synthesizer registers and the current PLL configuration setting, the user can 1) read PLL_L, PLL_H, write the GET

command (loads the current configuration into PLL_L, PLL_H) and read PLL_L, PLL_H again. Note that the PLL_L, PLL_H registers and divider settings may not be equivalent after the following cases:

- Writing the INC command
- Writing the DEC command
- Writing PLL_L, PLL_H registers with a new configuration and not writing the LOAD command.

Table 19. Configuration Register Read Transfer

1 bit	7 bits	1 bit	1 bit	8 bits	1 bit	8 bits	1 bit	1 bit
Start	Slave address	R/W	ACK	PLL_L	ACK	PLL_H	ACK	Stop
	10110xx ⁽¹⁾	1		Data		Data		
Master	Master	Mast	Slave	Slave	Mast	Slave	Master	Slave

1. xx = state of ADR1, ADR0 pins

Device Startup

General Device Configuration

It is recommended to reset the MPC92433 during or immediately after the system powers up ($\overline{MR} = 0$). The device acquires an initial PLL divider configuration through the parallel interface pins M[9:0], NA[2:0], N, and P⁽¹⁾ with the low-to-high transition of \overline{MR} ⁽²⁾. PLL frequency lock is achieved within the specified lock time (t_{LOCK}) and is indicated by an assertion of the LOCK signal which completes the startup procedure. It is recommended to disable the outputs ($CLK_STOPx = 0$) until PLL lock is achieved to suppress output frequency transitions. The output frequency can be reconfigured at any time through either the parallel or the serial interface.

Note that a PLL configuration obtained by the parallel interface can be read through I²C independent on the current programming mode (parallel or serial). Refer to the **I²C — Register Access in Parallel Mode** section for additional information on how to read a PLL startup configuration through the I²C interface.

Starting-Up Using the Parallel Interface

The simplest way to use the MPC92433 is through the parallel interface. The serial interface pins (SDA, SDL) and ADDR[1:0]) can be left open and \overline{PLOAD} is set to logic low. After the release of \overline{MR} and at any other time the PLL/output frequency configuration is directly set to through the M[9:0], NA[2:0], NB, and P pins.

Start-Up Using the Serial (I²C) Interface

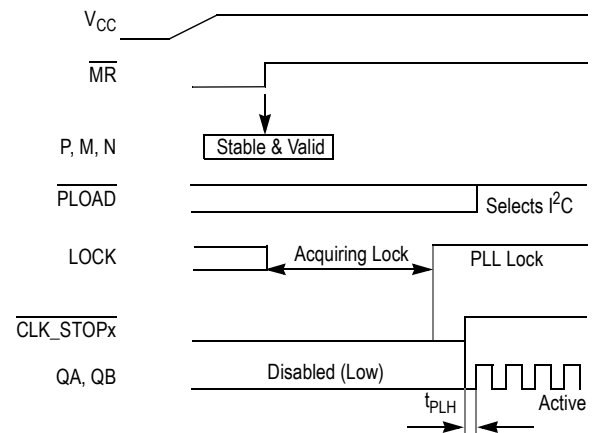

Figure 4. Start-Up Using I²C Interface

Set $\overline{PLOAD} = 1$, $\overline{CLK_STOPx} = L$ and leave the parallel interface pins (M[9:0], NA[2:0], N, and P) open. The PLL dividers are configured by the default configuration at the low-to-high transition of \overline{MR} . This initial PLL configuration can be re-programmed to the final VCO frequency at any time through the serial interface. After the PLL achieved lock at the desired VCO frequency, enable the outputs by setting $\overline{CLK_STOPx} = H$. PLL lock and re-lock (after any configuration change through M or P) is indicated by LOCK being asserted.

- The parallel interface pins M[9:0], NA[2:0], N, and P may be left open (floating). In this case the initial PLL configuration will have the default setting of M = 500, P = 1, NA[2:0] = 010, NB = 0, resulting in an internal VCO frequency of 2000 MHz ($f_{ref} = 16$ MHz) and an output frequency of 250 MHz.
- The initial PLL configuration is independent on the selected programming mode (\overline{PLOAD} low or high)

LOCK Detect

The LOCK detect circuitry indicates the frequency-lock status of the PLL by setting and resetting the pin LOCK and register bit LOCK simultaneously. After acquiring an internal frequency lock state, the assertion of the LOCK signal is delayed at least 256 reference clock cycles to prevent signaling temporary PLL locks during frequency transitions. The LOCK signal is deasserted when the PLL lost lock, for instance when the reference clock is removed: the LOCK signal goes low after missing at least two f_{ref} clock cycles ($N_{REF(UNLOCK)}$). The PLL may also lose lock when the PLL feedback-divider M or pre-divider P is changed or the DEC/INC command is issued. The PLL may not lose lock as a result of slow reference frequency changes. In any case of losing LOCK, the PLL attempts to re-lock to the reference frequency.

Output Clock Stop

Asserting $\overline{CLK_STOPx}$ will stop the respective output clock in logic low state. The $\overline{CLK_STOPx}$ control is internally synchronized to the output clock signal, therefore, enabling and disabling outputs does not produce runt pulses. See Figure 5. The clock stop controls of the QA and QB outputs are independent on each other. If the QB runs at half of the QA output frequency and both outputs are enabled at the same time, the first clock pulse of QA may not appear at the same time of the first QB output. (See Figure 6.) Coincident rising edges of QA and QB stay synchronous after the assertion and de-assertion of the $\overline{CLK_STOPx}$ controls. Asserting \overline{MR} always resets the output divider to a logic low output state, with the risk of producing an output runt pulse.

Figure 5. Clock Stop Timing for NB = 0 ($f_{QA} = f_{QB}$)

Figure 6. Clock Stop Timing for NB = 1 ($f_{QA} = 2 f_{QB}$)

Frequency Operating Range

V_{CC_PLL} Filter

The MPC92433 is a mixed analog/digital product. Its analog circuitry is naturally susceptible to random noise, especially if this noise is seen on the power supply pins. Random noise on the V_{CC_PLL} pin impacts the device AC characteristics. The MPC92433 provides separate power supplies for the digital circuitry (V_{CC}) and the internal PLL (V_{CC_PLL}) of the device. The purpose of this design technique is to isolate the high switching noise digital outputs from the relatively sensitive internal analog phase-locked loop. In digital system environments where it is more difficult to minimize noise on the power supplies a second level of isolation is recommended: a power supply filter on the V_{CC_PLL} pin for the MPC92433.

Figure 7. V_{CC_PLL} Power Supply Filter

Figure 7 illustrates a recommended power supply filter scheme.

The MPC92433 is most susceptible to noise with spectral content in the 100 kHz to 1 MHz range. Therefore, the filter should be designed to target this range. The key parameter that needs to be met in the final filter design is the DC voltage drop that will be seen between the V_{CC} supply and the V_{CC_PLL} pin of the MPC92433. From the data sheet, the V_{CC_PLL} current (the current sourced through the V_{CC_PLL} pin) is maximum 10 mA, assuming that a minimum of 2.985 V must be maintained on the V_{CC_PLL} pin. The resistor shown in Figure 7 must have a resistance of 10–15 Ω to meet the voltage drop criteria. The minimum values for R_F and the filter capacitor C_F are defined by the filter characteristics: the RC

filter should provide an attenuation greater than 40 dB for noise whose spectral content is above 100 kHz. In the recommended filter shown in Figure 7 the filter cut-off frequency is around 3.0–4.5 kHz and the noise attenuation at 100 kHz is better than 42 dB.

As the noise frequency crosses the series resonant point of an individual capacitor its overall impedance begins to look inductive and thus increases with increasing frequency. The parallel capacitor combination shown ensures that a low impedance path to ground exists for frequencies well above the bandwidth of the PLL.

The On-Chip Crystal Oscillator

The MPC92433 features an integrated on-chip crystal oscillator to minimize system implementation cost. The integrated oscillator is a Pierce-type that uses the crystal in its parallel resonance mode. It is recommended to use a 15 to 20 MHz crystal with a load specification of C_L = 10 pF. Crystals with a load specification of C_L = 20 pF may be used at the expense of an resulting slightly higher frequency than specified for the crystal. Externally connected capacitors on both the XTAL_IN and XTAL_OUT pins are not required but can be used to fine-tune the crystal frequency as desired.

The crystal, the trace and optional capacitors should be placed on the board as close as possible to the MPC92433 XTAL_IN and XTAL_OUT pins to reduce crosstalk of active signals into the oscillator. Short and wide traces further reduce parasitic inductance and resistance. It is further recommended to guard the crystal circuit by placing a ground ring around the traces and oscillator components.

Table 22. Recommended Crystal Specifications

Parameter	Value
Crystal Cut	Fundamental AT Cut
Resonance Mode	Parallel
Crystal Frequency	16–20 MHz
Shunt Capacitance C ₀	5–7 pF
Load Capacitance C _L	10 pF

Jitter Performance of the MPC92433

Figure 8 and Figure 9 illustrate the RMS jitter performance of the MPC92433 across its specified VCO frequency range. For some output dividers N, the cycle-to-cycle and period jitter is a function of the VCO frequency and the output divider N. The general trend is that as the output frequency increases (higher VCO frequency and lower N-divider) the MPC92433 output jitter decreases. Optimum jitter performance can be achieved at higher VCO and output frequencies.

For the output dividers of N=2, 4 and 6 the cycle-to-cycle jitter does not depend on the VCO frequency. For the output dividers of 2, 4 and 8 the period jitter does not depend on the VCO frequency. The maximum cycle-to-cycle and period jitter published in Table 6 (AC characteristics) correspond to the jitter performance at the lowest VCO frequency limit. The VCO frequency can be calculated using formula (2).

AC Test Reference and Output Termination

The MPC92433 LVPECL outputs are designed to drive 50 transmission lines and require a DC termination to $V_{TT} = V_{CC} - 2\text{ V}$. Figure 10 illustrates the AC test reference for the MPC92433 as used in characterization and test of this circuit. If a separate termination voltage (V_{TT}) is not available, applications may use alternative output termination methods such as shown in Figure 11 and Figure 12.

The high-speed differential output signals of the MPC92433 are incompatible to single-ended LVCMOS signals. In order to use the synthesizer in LVCMOS clock signal environments, the dual-channel translator device MC100ES60T23 provides the necessary level conversion. The MC100ES60T23 has been specifically designed to interface with the MPC92433 and supports clock frequencies up to 300 MHz.

OUTLINE DIMENSIONS

- NOTES:
1. DIMENSIONING AND TOLERANCING PER ASME Y14.5m, 1994.
 2. CONTROLLING DIMENSION: MILLIMETER.
 3. DATUM PLAN AB IS LOCATED AT BOTTOM OF LEAD AND IS COINCIDENT WITH THE LEAD WHERE THE LEAD EXITS THE PLASTIC BODY AT THE BOTTOM OF THE PARTING LINE.
 4. DATUMS T, U, AND Z TO BE DETERMINED AT DATUM PLANE AB.
 5. DIMENSIONS S AND V TO BE DETERMINED AT SEATING PLANE AC.
 6. DIMENSIONS A AND B DO NOT INCLUDE MOLD PROTRUSION. ALLOWABLE PROTRUSION IS 0.250 PER SIDE. DIMENSIONS A AND B DO INCLUDE MOLD MISMATCH AND ARE DETERMINED AT DATUM PLANE AB.
 7. DIMENSION D DOES NOT INCLUDE DAMBAR PROTRUSION. DAMBAR PROTRUSION SHALL NOT CAUSE THE D DIMENSION TO EXCEED 0.350.
 8. MINIMUM SOLDER PLATE THICKNESS SHALL BE 0.0076.
 9. EXACT SHAPE OF EACH CORNER IS OPTIONAL.

MILLIMETERS		
DIM	MIN	MAX
A	7.000	BSC
A1	3.500	BSC
B	7.000	BSC
B1	3.500	BSC
C	1.400	1.600
D	0.170	0.270
E	1.350	1.450
F	0.170	0.230
G	0.500 BSC	
H	0.050	0.150
J	0.090	0.200
K	0.500	0.700
L	0'	7'
M	12' REF	
N	0.090	0.160
P	0.250 BSC	
R	0.150	0.250
S	9.000 BSC	
S1	4.500	BSC
V	9.000 BSC	
V1	4.500	BSC
W	0.200 REF	
AA	1.000 REF
