

XR-2135A CCITT Data Buffer

GENERAL DESCRIPTION

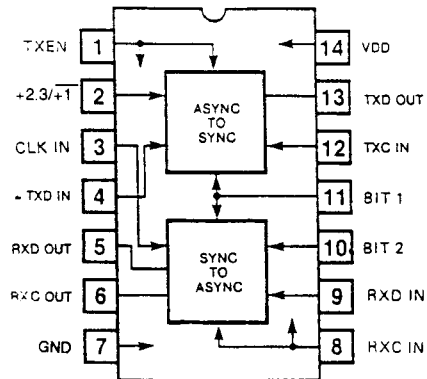

The XR-2135A is a digital circuit designed to perform the function of data buffering for various serial data systems, including modems. Both the asynchronous-to-synchronous conversion and the synchronous-to-asynchronous conversion are performed at data rates up to 19.2 kbps. The XR-2135A is selectable for character lengths of 8, 9, 10 and 11 bits. A combined enable/disable input is supplied for the synchronous-to-synchronous and asynchronous-to-synchronous converter sections. This input allows the same data lines to be used for synchronous or asynchronous modes of operation.

The receive data buffer (synchronous-to-asynchronous) accepts input synchronous data along with a receive clock and converts this to an asynchronous format. The transmit data buffer (asynchronous-to-synchronous) accepts on the input asynchronous data and will synchronize the data to a transmit clock. The transmit data input can accept data from -2.5% underspeed up to +2.3% overspeed in 8, 9, 10 bit and 11 bit word modes. The +2.,3/+1* pin selects the overspeed capability. Automatic break extension is included in case of a break being received. The XR-2135A is constructed using polysilicon gate CMOS technology for low power and high speed operation. The master clock (CLK IN) can be clocked at speed up to 4.9152 MHz (19.2 kbps data rate). The XR-2135A, available in a 14 pin package, is designed to operate with a single 5V supply.

FEATURES

- Data Rates up to 19.2 kbps
- Asynchronous-to-Synchronous Conversion
- Synchronous-to-Asynchronous Conversion
- Independent Disable Inputs for Receiver and Transmitter Sections
- Single 5 Volt Supply Operation
- Underspeed and Overspeed capability of -2.5% to +1% or +2.5% to +2.3%
- Missing Stop bit detector
- Break extended for transmitted data
- Programmable Character Lengths of 8, 9, 10 or 11 bits

PIN ASSIGNMENT

ORDERING INFORMATION

Part Number	Package	Operating Temperature
XR-2135ACN	Ceramic	0°C to 70°C
XR-2135ACP	Plastic	0°C to 70°C

APPLICATIONS

- Modem Data Buffers
- Terminals
- Data Communication Test Equipment

ABSOLUTE MAXIMUM RATINGS

Power Supply	-0.3 to +7.0 V
Input Voltage	-0.3 to VDD + 0.3V
DC Input Current (any input)	±10 mA
Power Dissipation (Package Limitation)	250 mW
Storage Temperature Range	65°C to +125°C

XR-2135A

ELECTRICAL CHARACTERISTICS

Test Conditions: VDD = 5VDC \pm 5%, TA = 25°C, CLK IN = 307.2 KHz \pm 0.01%,

Data Rate - 1200 BPS f_{TXC} IN = 1200 Hz f_{RXC} IN= 1200 Hz \pm 0.01%, unless otherwise specified.

SYMBOL	PARAMETER	MIN	TYP	MAX	UNIT	CONDITIONS
DC CHARACTERISTICS						
V _{OL}	Output Low Voltage			0.05	V	I _{OL} = 20 μ A
V _{OH}	Output High Voltage	4.8	5.0		V	I _{OH} = -20 μ A
V _{IL}	Input Low Voltage			0.8	V	
V _{IH}	Input High Voltage	2.4			V	
I _{OL}	Output Low Current	2	7		mA	
I _{OH}	Output High Current		-9	-400	μ A	
I _{IN}	Input Leakage Current	-10	0	10	μ A	
I _{DD}	Supply Current Quiescent		100	250	μ A	CLK IN, TXCIN, RXC IN At 5VDC
AC CHARACTERISTICS						
t _{wstr}	Start Bit Width	819	821		μ S	B1 = 1 B2 = 0 (10 bit)
BPS RANGE	Receiver Transmit	1170	1200	1212	BPS	8, 9, and 10 Bit Mode
f _{RXCO}	RXC OUTfrequency Multiplier	1.015			Hz/Hz	RXC OUT=1219 Hz

SYSTEM DESCRIPTION

The XR-2135A provides the complete interface between synchronous and character asynchronous formatted data systems. The synchronous side consists of two data lines TXD IN and RXD IN each with their respective clocks, TXC and RXC. Received data should change on the falling edge of RXC and be stable on the rising edge of RXC. The asynchronous-to-synchronous conversion handles data that is formatted so that the data bits or data and parity bits are bracketed by start and stop bits. Acceptable character lengths are 8, 9, 10 and 11 bits. The word length is pin selectable.

The XR-2135A is optimized for applications where a single clock is the source for the master clock (CLK IN), the TXDIN IN and RXC IN. The master clock (CLK IN) is 256 times the data rate. In modem applications, the RXC IN should be in lock with the received data, and jitter should be less than ± 30 ns. The asynchronous transmit data being clock in by an asynchronous clock at the data rate (CLK IN/256). The asynchronous-to-synchronous converter when receiving overspeed data will shave on the stop bit. The break signal extended will detect a missing stop bit and extend this an additional character length and 3 bits.

PRINCIPLES OF OPERATION

The XR-2135A data buffer can be separated into three blocks: the asynchronous-to-synchronous converter for the transmitted data, the synchronous-to-asynchronous converter for the received data and the master clock divider.

The asynchronous-to-synchronous converter uses a two bit shift register to allow resetting of the stop bit to compensate for underspeed conditions.

A counter circuit, synchronized to the location of the stop start bit occurrence is used to control when the stop bit needs to be adjusted. An 11 bit shift register is used to monitor the data for the occurrence of a break signal.

The break extended is activated by the continuous reception of a series of logic 0s for one entire word's time (8, 9, 10 or 11 bits depending upon the setting of BIT 2 and BIT 1). When this occurs, the synchronized register is reset, and 2 words + 3 bits of logic 0s are shifted out and appear at TXD OUT.

If 1% overspeed data is received, and the modem is selected for 8, 9, 10 or 11 bit word operation, the stop bit in the word will be increased in width. In the case of underspeed, the stop bit will be truncated, when the one bit shift register is reset. When the +2.3% mode is selected the operation remains the same, only a different timer is used to determine the location of the stop bit.

The enable pin, Pin 1, controls the bypassing of the asynchronous-to-synchronous converter and the synchronous-to-asynchronous converter. The bypass mode is buffered and the delay through the buffer is less than 30 ns.

The synchronous to asynchronous converter contains a 21 bit synchronous shift register and a 8,9, 10 or 11 bit programmable parallel loading asynchronous shift register also uses a stop-start bit detector. The difference is that a missing stop bit detector is needed for synchronous data that is received without a stop bit. When this occurs, the last stage of the asynchronous shift register is set, and a stop bit re-inserted. The asynchronous shift register is clocked at a rate that is 1.015 times the nominal data rate. For 1200 BPS, this is 1219. For 9600 BPS, the rate would be 9744 BPS.

The master clock divider takes the CLK IN and divides by 256 to provide the internal data clocks as well as producing various reset pulses to perform the functions described above.

PIN DESCRIPTIONS

PIN# SYMBOL DESCRIPTION

PIN#	SYMBOL	DESCRIPTION
1	TXEN	Enable Input: This input when tied to a logic high permits the TXD IN to be clocked through the asynchronous-to-synchronous converter. When this input is tied to a logic low, the shift registers of the asynchronous-to-synchronous converter and synchronous-to-asynchronous converters are bypassed and both TXEN and RXD IN are buffered and connected.
2	+2.3/+1	Overspeed Enable Input: This input when tied to a logic high enables the asynchronous-to-synchronous converter to accept data at a rate from -2.5% to +1%. When disabled,

XR-2135A

PIN#	SYMBOL	DESCRIPTION	PIN#	SYMBOL	DESCRIPTION
3	CLK IN	Master Clock Input: This clock provides the asynchronous clocks and reset pulses used by the XR-2135 to perform the asynchronous-to-synchronous conversion as well as the synchronous to asynchronous conversion. The formula to use for determining the datarate is CLK IN / 256-data rate in BPS.	11	BIT 1	These two digital inputs control the length of the word that will be applied to the XR-2135. Refer to Table 2 for the truth table of the function.
4	TXD IN	Transmit Data Input: The serial data should be applied to this pin. When 8, 9, or 10 bits are selected, the range for the data rate is -2.5% to +1%. This input has a high input impedance.	12	TXC IN	Transmit Clock Input: The system clock that the transmit data is to be synchronized to be tied to this pin. Note that this clock must be locked to the master clock CLK IN. Acceptable variation is +0.01%. In many modem applications this is not a problem.
5	RXD OUT	Received Data Output: This is the asynchronous received data output (when TXEN is tied high). The data rate of this output is 1.5 times the synchronous data rate.	13	TXDOUT	Transmit Data Output: This output provides the serial data synchronous to the clock applied to TXCIN if TXEN is at a logic high. In an underspeed situation, all bits will be shortened. In an over-speed situation, all bits will be widened. If TXEN is at a logic low this output will provide a buffered version the data at TXD IN. The amount of delay is 30 ns.
6	RXC OUT	Received Clock Output: This clock is synchronized with the RXD OUT. It should be noted that when stop bits are being inserted or deleted, the clock will produce a pulse at the time of the stop bit being shifted out at RXD OUT.	14	V _{DD}	Positive Supply: This input should be tied to 5 V \pm 5%. A 0.1 μ F decoupling capacitor should be adequate for decoupling any system noise to ground.
7	GND	This pin should be tied to the digital ground of the XR-2135.			
8	RXC IN	Receive Clock Input: The received clock synchronous with the received data should be tied to this pin. The acceptable jitter is only \pm 30ns relative to the data. The data should be stable on the rising edge of this clock and change on the falling edge. If the received data is bit asynchronous (no clock relative to the data) this pin does not have to be clock for the data to appear at RXD OUT if TXEN is at a logic low.			
9	RXD IN	Received Data input: The synchronous data is applied to this pin.
