Wideband FM IF Subsystem

The MC13158 is a wideband IF subsystem that is designed for high performance data and analog applications. Excellent high frequency performance is achieved, with low cost, through the use of Motorola's MOSAIC 1.5™ RF bipolar process. The MC13158 has an on-board grounded collector VCO transistor that may be used with a fundamental or overtone crystal in single channel operation or with a PLL in multi-channel operation. The mixer is useful to 500 MHz and may be used in a balanced differential or single ended configuration. The IF amplifier is split to accommodate two low cost cascaded filters. RSSI output is derived by summing the output of both IF sections. A precision data shaper has an Off function to shut the output off to save current. An enable control is provided to power down the IC for power management in battery operated applications.

Applications include DECT, wideband wireless data links for personal and portable laptop computers and other battery operated radio systems which utilize GFSK, FSK or FM modulation.

- Designed for DECT Applications
- 1.8 to 6.0 Vdc Operating Voltage
- Low Power Consumption in Active and Standby Mode
- Greater than 600 kHz Detector Bandwidth
- Data Slicer with Special Off Function
- Enable Function for Power Down of Battery Operated Systems
- RSSI Dynamic Range of 80 dB Minimum
- Low External Component Count

CIRCUIT DESCRIPTION

General

The MC13158 is a low power single conversion wideband FM receiver incorporating a split IF. This device is designated for use as the backend in digital FM systems such as Digital European Cordless Telephone (DECT) and wideband data links with data rates up to 2.0 Mbps. It contains a mixer, oscillator, Received Signal Strength Indicator (RSSI), IF amplifier, limiting IF, quadrature detector, power down or enable function, and a data slicer with output off function. Further details are covered in the Pin Function Description which shows the equivalent internal circuit and external circuit requirements.

Current Regulation/Enable

Temperature compensating voltage independent current regulators which are controlled by the enable pin (Pin 25) where "low" powers up and "high" powers down the entire circuit.

Mixer

The mixer is a double-balanced four quadrant multiplier and is designed to work up to 500 MHz. It can be used in differential or in single ended mode by connecting the other input to the positive supply rail. The linear gain of the mixer is approximately 22 dB at 100 mVrms LO drive level. The mixer gain and noise figure have been emphasized at the expense of intermodulation performance. RSSI measurements are added in the mixer to extend the range to higher signal levels. The single-ended parallel equivalent input impedance of the mixer is $R_p \sim 1.0 \text{ k}\Omega$ and $C_p \sim 2.0 \text{ pF}$. The buffered output of the mixer is internally loaded resulting in an output impedance of 330 Ω .

Local Oscillator

The on-chip transistor operates with crystal and LC resonant elements up to 220 MHz. Series resonant, overtone crystals are used to achieve excellent local oscillator stability. Third overtone crystals are used through about 65 to 70 MHz. Operation from 70 MHz up to 180 MHz is feasible using the on-chip transistor with a 5th or 7th overtone crystal. To enhance operation using an overtone crystal, the internal transistor bias is increased by adding an external resistor from Pin 29 to V_{EE} ; however, with an external resistor the oscillator stays on during power down. Typically, -10 dBm of local oscillator drive is needed to adequately drive the mixer. With an external oscillator source, the IC can be operated up to 500 MHz.

RSSI

The received signal strength indicator (RSSI) output is a current proportional to the log of the received signal amplitude. The RSSI current output is derived by summing the currents from the mixer, IF and limiting amplifier stages. An increase in RSSI dynamic range, particularly at higher input signal levels is achieved. The RSSI circuit is designed to provide typically 85 dB of dynamic range with temperature compensation.

Linearity of the RSSI is optimized by using external ceramic bandpass filters which have an insertion loss of 4.0 dB and 330 Ω source and load impedance. For higher data rates used in DECT and related applications, LC bandpass filtering is necessary to acquire the desired

bandpass response; however, the RSSI linearity will require the same insertion loss.

RSSI Buffer

The RSSI output current creates a voltage across an external resistor. A unity voltage-gain amplifier is used to buffer this voltage. The output of this buffer has an active pull-up but no pull-down, so it can also be used as a peak detector. The negative slew rate is determined by external capacitance and resistance to the negative supply.

IF Amplifier

The first IF amplifier section is composed of three differential stages with the second and third stages contributing to the RSSI. This section has internal DC feedback and external input decoupling for improved symmetry and stability. The total gain of the IF amplifier block is approximately 40 dB at 10.7 MHz.

The fixed internal input impedance is 330 Ω . When using ceramic filters requiring source and load impedances of 330 Ω , no external matching is necessary. Overall RSSI linearity is dependent on having total midband attenuation of 10 dB (4.0 dB insertion loss plus 6.0 dB impedance matching loss) for the filter. The output of the IF amplifier is buffered and the impedance is 330 Ω .

Limiter

The limiter section is similar to the IF amplifier section except that five differential stages are used. The fixed internal input impedance is 330 Ω . The total gain of the limiting amplifier section is approximately 70 dB. This IF limiting amplifier section internally drives the quadrature detector section and it is also brought out on Pin 12.

Quadrature Detector

The quadrature detector is a doubly balanced four quadrant multiplier with an internal 5.0 pF quadrature capacitor between Pins 12 and 13. An external capacitor may be added between these pins to increase the IF signal to the external parallel RLC resonant circuit that provides the 90 degree phase shift and drives the quadrature detector. A single pin (Pin 13) provides for the external LC parallel resonant network and the internal connection to the quadrature detector.

Internal low pass filter capacitors have been selected to control the bandwidth of the detector. The recovered signal is brought out by the inverting amplifier buffer. An external feedback resistor from the output (Pin 17) to the input of the inverting amplifier (Pin 15) controls the output amplitude; it is combined with another external resistor from the input to the negative supply (Pin 16) to set the output dc level. For a resistor ratio of 1, the DC level at the detector output is $2.0 V_{BE}$ (see Figure 12). A small capacitor C_{17} across the first resistor (from Pin 17 to 15) can be used to reduce the bandwidth.

Data Slicer

The data slicer is a comparator that is designed to square up the data signal. Across the data slicer inputs (Pins 18 and 20) are back to back diodes.

Freescale Semiconductor, Inc. ARCHIVED BY FREESCALE SEMICONDUCTOR, INC. 2005

ARCHIVE INFORMATION

Freescale Semiconductor, Inc.

The recovered data signal from the quadrature detector can be DC coupled to the data slicer DS IN1 (Pin 18). In the application circuit shown in Figure 1 it will be centered at $2.0 V_{BE}$ and allowed to swing $\pm V_{BE}$. A capacitor is placed from DS IN2 (Pin 20) to V_{EE} . The size of this capacitor and the nature of the data signal determine how faithfully the data slicer shapes up the recovered signal. The time constant is short for large peak to peak voltage swings or when there is a change in DC level at the detector output. For small signal or for continuous bits of the same polarity which drift close to the threshold voltage, the time constant is longer.

A unique feature of the data slicer is that the inverting switching stages in the comparator are supplied through the emitter pin of the output transistor (Pin 22 – DS Gnd) to V_{EE} rather than internally to V_{EE} . This is provided in order to reduce switching feedback to the front end. A control pin is provided to shut the data slicer output off (DS "off" – Pin 19). With DS "off" pin at V_{CC} the data slicer output is shut off by shutting down the base drive to the output transistor. When a channel is being monitored to make an RSSI measurement, but not to collect data, the data output may be shut off to save current.

PIN FUNCTION DESCRIPTION

Pin	Symbol	Internal Equivalent Circuit	Description/External Circuit Requirements
1	Mix Out		<p>Mixer Output The mixer output impedance is 330 Ω; it matches to 10.7 MHz ceramic filters with 330 Ω input impedance.</p> <p>Supply Voltage (V_{CC1}) This pin is the V_{CC} pin for the Mixer, Local Oscillator, and IF Amplifier. The operating supply voltage range is from 1.8 Vdc to 5.0 Vdc. In the PCB layout, the V_{CC} trace must be kept as wide as possible to minimize inductive reactances along the trace; it is best to have it completely fill around the surface mount components and traces on the circuit side of the PCB.</p>
2	V_{CC1}		<p>IF Input The input impedance at Pin 3 is 330 Ω. It matches the 330 Ω load impedance of a 10.7 MHz ceramic filter. Thus, no external matching is required.</p> <p>IF DEC1 & DEC2 IF decoupling pins. Decoupling capacitors should be placed directly at the pins to enhance stability. Two capacitors are decoupled to the RF ground V_{CC1}; one is placed between DEC1 & DEC2.</p>
3	IF In		<p>IF Output The output impedance is 330 Ω; it matches the 330 input resistance of a 10.7 MHz ceramic filter.</p>
4	IF Dec1		<p>IF Output The output impedance is 330 Ω; it matches the 330 input resistance of a 10.7 MHz ceramic filter.</p>
5	IF Dec2		
6	IF Out

PIN FUNCTION DESCRIPTION (continued)

Pin	Symbol	Internal Equivalent Circuit	Description/External Circuit Requirements
7	V _{CC2}		<p>Supply Voltage (V_{CC2}) This pin is V_{CC} supply for the Limiter, Quadrature Detector, data slicer and RSSI buffer circuits. In the application PC board this pin is tied to a common V_{CC} trace with V_{CC1}.</p> <p>Limiter Input The limiter input impedance is 330 Ω.</p> <p>Limiter Decoupling Decoupling capacitors are placed directly at these pins and to V_{CC} (RF ground). Use the same procedure as in the IF decoupling.</p>
8	Lim In		
9	Lim Dec1		
10	Lim Dec2		
11,14, 27 & 28	N/C		<p>No Connects There is no internal connection to these pins; however it is recommended that these pins be connected externally to V_{CC} (RF ground).</p>
12	Lim Out		<p>Limiter Output The output impedance is low. The limiter drives a quadrature detector circuit with in-phase and quadrature phase signals.</p> <p>Quadrature Detector Circuit The quadrature detector is a doubly balanced four-quadrant multiplier with an internal 5.0 pF capacitor between Pins 12 and 13. An external capacitor may be added to increase the IF signal to Pin 13. The quadrature detector pin is provided to connect the external RLC parallel resonant network which provides the 90 degree phase shift and drives the quadrature detector.</p>
13	Quad		
15	Det Gain		<p>Detector Buffer Amplifier This is an inverting amplifier. An external feedback resistor from Pin 17 to 15, (the inverting input) controls the output amplitude; another resistor from Pin 15 to the negative supply (Pin 16) sets the DC output level. A 1:1 resistor ratio sets the output DC level at two V_{BE} with respect to V_{EE}. A small capacitor from Pin 17 to 15 can be used to set the bandwidth.</p> <p>Supply Ground (VEE2) In the PCB layout, the ground pins (also applies to Pin 26) should be connected directly to chassis ground. Decoupling capacitors to V_{CC} should be placed directly at the ground pins.</p>
17	Det Out		
16	VEE2

PIN FUNCTION DESCRIPTION (continued)

Pin	Symbol	Internal Equivalent Circuit	Description/External Circuit Requirements	
19	DS "off"		<p>Data Slicer Off The data output may be shut off to save current by placing DS "off" (Pin 19) at V_{CC}.</p> <p>Data Slicer Output In the application example a 10 kΩ pull-up resistor is connected to the collector of the output transistor at Pin 21.</p> <p>Data Slicer Ground All the inverting switching stages in the comparator are supplied through the emitter pin of the output transistor (Pin 22) to ground rather than internally to V_{EE} in order to reduce switching feedback to the front end.</p>	
21	DS Out			<p>Data Slicer Inputs The data slicer has differential inputs with back to back diodes across them. The recovered signal is DC coupled to DS IN1 (Pin 18) at nominally V₁₈ with respect to V_{EE}; thus, it will maintain V₁₈ ± V_{BE} at Pin 18. DS IN2 (Pin 20) is AC coupled to V_{EE}. The choice of coupling capacitor is dependent on the nature of the data signal. For small signal or continuous bits of the same polarity, the response time is relatively large. On the other hand, for large peak to peak voltage swings or when the DC level at the detector output changes, the response time is short. See the discussion in the application section for external circuit design details.</p>
22	DS Gnd			
18	DS In1	20	DS In2	
23	RSSI Buf	24	RSSI	

Freescale Semiconductor, Inc.

PIN FUNCTION DESCRIPTION (continued)

Pin	Symbol	Internal Equivalent Circuit	Description/External Circuit Requirements
25	Enable		<p>Enable</p> <p>The IC regulators are enabled by placing this pin at V_{EE}.</p>
26	V_{EE1}		<p>V_{CC} and V_{EE} ESD Protection</p> <p>ESD protection diodes exist between the V_{CC} and V_{EE} pins. It is important to note that significant differences in potential ($> 0.5 V_{BE}$) between the two V_{CC} pins or between the V_{EE} pins can cause these structures to start to conduct, thus compromising isolation between the supply busses. V_{CC1} & V_{CC2} should be maintained at the same DC potential, as should V_{EE1} & V_{EE2}.</p>
28	Osc Base		<p>Oscillator Base</p> <p>This pin is connected to the base lead of the common collector transistor. Since there is no internal bias resistor to the base, V_{CC} is applied through an external choke or coil.</p>
29	Osc Emitter		<p>Oscillator Emitter</p> <p>This pin is connected to the emitter lead; the emitter is connected internally to a current source of about $200 \mu A$. Additional emitter current may be obtained by connecting an external resistor to V_{EE}; $I_E = V_{29}/R_{29}$.</p> <p>Details of circuits using overtone crystal and LC varactor controlled oscillators are discussed in the application section.</p>
31	Mix In1		<p>Mixer Inputs</p> <p>The parallel equivalent differential input impedance of the mixer is approximately $2.0 k\Omega$ in parallel with $1.0 pF$. This equates to a single ended input impedance of $1.0 k\Omega$ in parallel with $2.0 pF$.</p> <p>The application circuit utilizes a SAW filter having a differential output that requires a $2.0 k\Omega \parallel 2.0 pF$ load. Therefore, little matching is required between the SAW filter and the mixer inputs. This and alternative circuits are discussed in more detail in the application section.</p>

APPLICATIONS INFORMATION

Evaluation PC Board

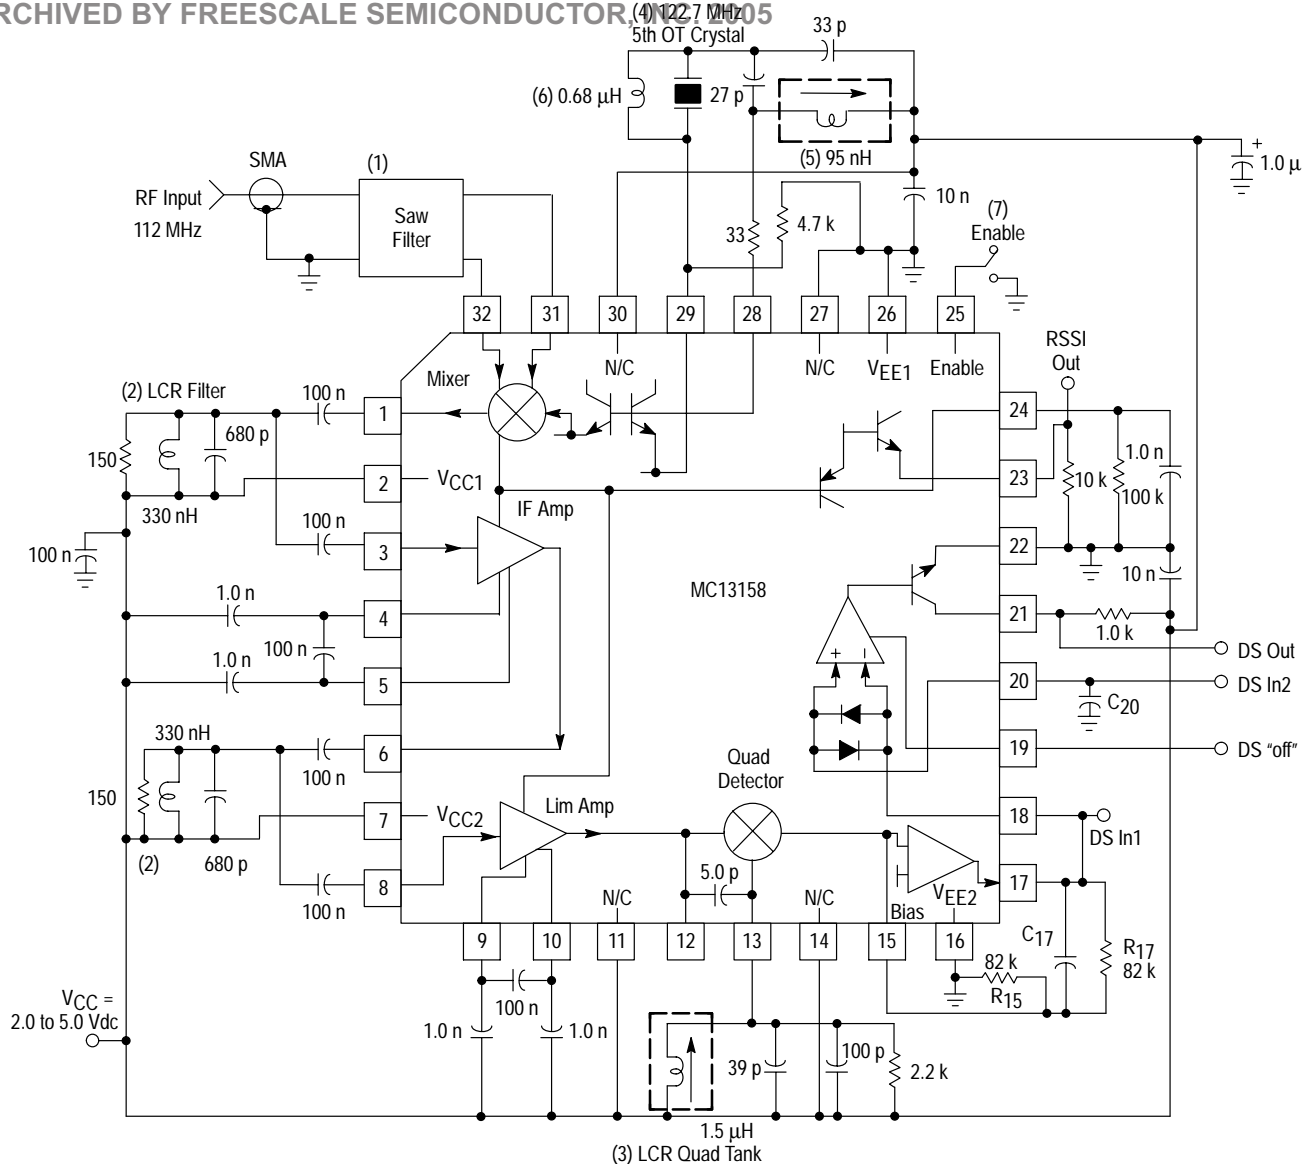

The evaluation PCB is very versatile and is intended to be used across the entire useful frequency range of this device. The center section of the board provides an area for attaching all SMT components to the circuit side and radial leaded components to the component ground side (see Figures 29 and 30). Additionally, the peripheral area surrounding the RF core provides pads to add supporting and interface circuitry as a particular application dictates. This evaluation board will be discussed and referenced in this section.

Component Selection

The evaluation PC board is designed to accommodate specific components, while also being versatile enough to use components from various manufacturers and coil types. Figures 13 and 14 show the placement for the components specified in the application circuit (Figure 12). The application circuit schematic specifies particular components that were used to achieve the results shown in the typical curves and tables but alternate components should give similar results.

Figure 12. Application Circuit

ARCHIVED BY FREESCALE SEMICONDUCTOR, INC. 2005

- NOTES:**
1. Saw Filter – Siemens part number Y6970M(5 pin SIP plastic package).
 2. An LCR filter reduces the broadband noise in the IF; ceramic filters may be used for data rates under 500 kHz. 4.0 dB insertion loss filters optimize the linearity of RSSI.
 3. The quadrature tank components are chosen to optimize linearity of the recovered signal while maintaining adequate recovered signal level. 1.5 μH 7.0 mm variable shielded inductor: Toko part # 292SNS-T1373Z. The shunt resistor is approximately equal to $Q(2\pi fL)$, where $Q \sim 18$ (3.0 dB BW = 600 kHz).
 4. The local oscillator utilizes a 122.7 MHz, 5th overtone, series resonant crystal specified with a frequency tolerance of 25 PPM, ESR of 120 Ω max. The oscillator configuration is an emitter coupled butler.
 5. The 95 nH (Nominal) inductor is a 7.0 mm variable shielded inductor: Coilcraft part # 150-04J08S or equivalent.
 6. 0.68 μH axial lead chokes (molded inductor): Coilcraft part # 90-11.
 7. To enable the IC, Pin 25 is taken to VEE. The external pull down resistor at Pin 29 could be linked to the enable function; otherwise if it is taken to VEE as shown, it will keep the oscillator biased at about 500 μA depending on the VCC level.
 8. The other resistors and capacitors are surface mount components.

Input Matching/Components

It is desirable to use a SAW filter before the mixer to provide additional selectivity and adjacent channel rejection. In a wideband system the primary sensitivity of the receiver backend may be achieved before the last mixer. Bandpass filtering in the limiting IF is costly and difficult to achieve for bandwidths greater than 280 kHz.

The SAW filter should be selected to easily interface with the mixer differential input impedance of approximately 2.0 k Ω in parallel with 1.0 pF. The PC board is dedicated to the Siemens SAW filter (part number Y6970M); the part is designed for DECT at 112 MHz 1st IF frequency. It is designed for a load impedance of 2.0 k Ω in parallel with

2.0 pF; thus, no or little input matching is required between the SAW filter and the mixer.

The Siemens SAW filter has an insertion loss of typically 10 dB and a 3.0 dB bandwidth of 1.0 MHz. The relatively high insertion loss significantly contributes to the system noise and a filter having lower insertion loss would be desirable. In existing low loss SAW filters, the required load impedance is 50 Ω ; thus, interface matching between the filter and the mixer will be required. Figure 15 is a table of the single-ended mixer input impedance. A careful noise analysis is necessary to determine the secondary contribution to system noise.

Figure 15. Mixer Input Impedance
(Single-ended)

f (MHz)	Rs (Ω)	Xs (Ω)	Rp (Ω)	Xp (Ω)	Cp (pF)
50	930	-350	1060	-2820	1.1
100	480	-430	865	-966	1.6
150	270	-400	860	-580	1.8
200	170	-320	770	-410	1.9
250	130	-270	690	-330	1.85
300	110	-250	680	-300	1.8
400	71	-190	580	-220	1.8
500	63	-140	370	-170	1.9
600	49	-110	300	-130	2.0

System Noise Considerations

The system block diagram in Figure 16 shows the cascaded noise stages contributing to the system noise; it represents the application circuit in Figure 12 and a low noise preamp using a MRF941 transistor (see Figure 17). The preamp is designed for a conjugately matched input and output at 2.0 Vdc V_{CE} and 3.0 mAdc I_C . S-parameters at 2.0 V, 3.0 mA and 100 MHz are:

$$\begin{aligned} S_{11} &= 0.86, -20 \\ S_{21} &= 9.0, 164 \\ S_{12} &= 0.02, 79 \\ S_{22} &= 0.96, -12 \end{aligned}$$

The bias network sets V_{CE} at 2.0 V and I_C at 3.0 mA for $V_{CC} = 3.0$ to 3.5 Vdc. The preamp operates with 18 dB gain and 2.7 dB noise figure.

In the cascaded noise analysis the system noise equation is:

$$F_{\text{system}} = F_1 + [(F_2 - 1)/G_1] + [(F_3 - 1)]/[(G_1)(G_2)]$$

where:

- F1 = the Noise Factor of the Preamp
- G1 = the Gain of the Preamp
- F2 = the Noise factor of the SAW Filter
- G2 = the Gain of the SAW Filter
- F3 = the Noise factor of the Mixer

Note: the proceeding terms are defined as linear relationships and are related to the log form for gain and noise figure by the following:

$$F = \log^{-1}[(NF \text{ in dB})/10] \text{ and similarly}$$

$$G = \log^{-1}[(Gain \text{ in dB})/10]$$

The noise figure and gain measured in dB are shown in the system block diagram. The mixer noise figure is typically 14 dB and the SAW filter adds typically 10 dB insertion loss. Addition of a low noise preamp having a 18 dB gain and 2.7 dB noise figure not only improves the system noise figure but it increases the reverse isolation from the local oscillator to the antenna input at the receiver. Calculating in terms of gain and noise factor yields the following:

$$\begin{aligned} F_1 &= 1.86; G_1 = 63.1 \\ F_2 &= 10; G_2 = 0.1 \\ F_3 &= 25.12 \end{aligned}$$

Thus, substituting in the equation for system noise factor:

$$F_{\text{system}} = 5.82; NF_{\text{system}} = 7.7 \text{ dB}$$

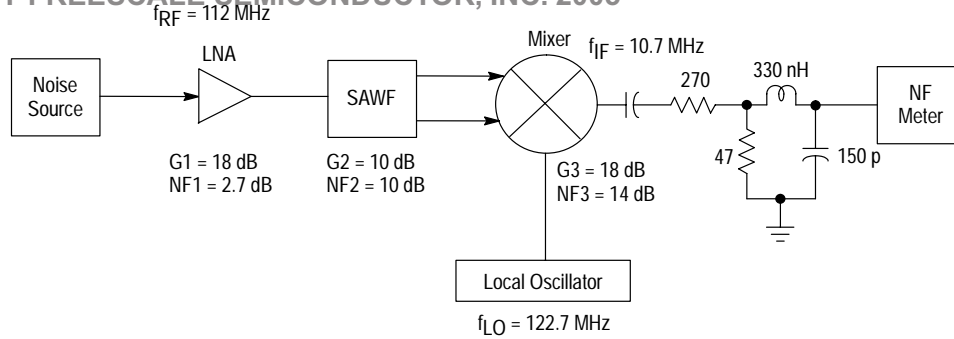

Figure 17. 112 MHz LNA

LOCAL OSCILLATORS

VHF Applications

The on-chip grounded collector transistor may be used for HF and VHF local oscillator with higher order overtone crystals. The local oscillator in the application circuit (Figure 12) shows a 5th overtone oscillator at 122.7 MHz. This circuit uses a Butler overtone oscillator configuration. The amplifier is an emitter follower. The crystal is driven from the emitter and is coupled to the high impedance base through a capacitive tap network. Operation at the desired overtone frequency is ensured by the parallel resonant circuit formed by the variable inductor and the tap capacitors and parasitic capacitances of the on-chip transistor and PC board. The variable inductor specified in the schematic could be replaced with a high tolerance, high Q ceramic or air wound surface mount component if the other components have tight enough tolerances. A variable inductor provides an adjustment for gain and frequency of the resonant tank ensuring lock up and start-up of the crystal oscillator. The overtone crystal is chosen with ESR of typically 80 Ω and 120 Ω maximum; if the resistive loss in the crystal is too high the performance of oscillator may be impacted by lower gain margins.

A series LC network to ground (which is V_{CC}) is comprised of the inductance of the base lead of the on-chip transistor and PC board traces and tap capacitors. Parasitic oscillations often occur in the 200 to 800 MHz range. A small resistor is placed in series with the base (Pin 28) to cancel the

negative resistance associated with this undesired mode of oscillation. Since the base input impedance is so large a small resistor in the range of 27 to 68 Ω has very little effect on the desired Butler mode of oscillation.

The crystal parallel capacitance, C_O, provides a feedback path that is low enough in reactance at frequencies of 5th overtones or higher to cause trouble. C_O has little effect near resonance because of the low impedance of the crystal motional arm (R_m-L_m-C_m). As the tunable inductor which forms the resonant tank with the tap capacitors is tuned "off" the crystal resonant frequency it may be difficult to tell if the oscillation is under crystal control. Frequency jumps may occur as the inductor is tuned. In order to eliminate this behavior an inductor, L_O, is placed in parallel with the crystal. L_O is chosen to be resonant with the crystal parallel capacitance, C_O, at the desired operation frequency. The inductor provides a feedback path at frequencies well below resonance; however, the parallel tank network of the tap capacitors and tunable inductor prevent oscillation at these frequencies.

IF Filtering/Matching

In wideband data systems the IF bandpass needed is greater than can be found in low cost ceramic filters operating at 10.7 MHz. It is necessary to bandpass limit with LC networks or series-parallel ceramic filter networks. Murata offers a series-parallel resonator pair (part number

Freescale Semiconductor, Inc. ARCHIVED BY FREESCALE SEMICONDUCTOR, INC. 2005

ARCHIVE INFORMATION

KMFC545) with a 3.0 dB bandwidth of ± 325 kHz and a maximum insertion loss of 5.0 dB. The application PC board is laid out to accommodate this filter pair (a filter pair is used at both locations of the split IF). However, even using a series parallel ceramic filter network yields only a maximum bandpass of 650 kHz. In some applications a wider band IF bandpass is necessary.

A simple LC network yields a bandpass wider than the SAW filter but it does reduce an appreciable amount of wideband IF noise. In the application circuit an LC network is specified using surface mount components. The parallel LC components are placed between the outputs of the mixer and IF amplifier to the V_{CC} trace; internal 330 loads are connected from the mixer and IF amplifier outputs to DEC2 (Pin 5 and 10 respectively). This loads the outputs with the optimal load impedance but creates a low insertion loss filter. An external shunt resistor may be used to widen the bandpass and to acquire the 10 dB composite loss necessary to linearize the RSSI output. The equivalent circuit is shown in Figure 18.

Figure 18. IF LCR Filter

The following equations satisfy the 12 dB loss (1:4 resistive ratio):

$$\begin{aligned} \text{Rext}(330)/(\text{Rext} + 330) &= \text{Requivalent} \\ \text{Requivalent}/(\text{Requivalent} + 330) &= 1/4 \end{aligned}$$

Solve for Requivalent:

$$\begin{aligned} 4(\text{Requivalent}) &= \text{Requivalent} + 330 \\ 3(\text{Requivalent}) &= 330 \\ \text{Requivalent} &= 110 \end{aligned}$$

Substitute for Requivalent and solve for Rext:

$$\begin{aligned} 330(\text{Rext}) &= 110(\text{Rext}) + (330)(110) \\ \text{Rext} &= (330)(110)/220 \\ \text{Rext} &= 165 \Omega \end{aligned}$$

The IF is 10.7 MHz although any IF between 10 to 20 MHz could be used. The value of the coil is lowered from that used in the quadrature circuit because the unloaded Q must be maintained in a surface mount component. A standard value component having an unloaded Q = 100 at 10.7 MHz is 330 nH; therefore the capacitor is 669 pF. Standard values have been chosen for these components;

$$\begin{aligned} \text{Rext} &= 150 \Omega \\ \text{C} &= 680 \text{ pF} \\ \text{L} &= 330 \text{ nH} \end{aligned}$$

Computation of the loaded Q of this LCR network is

$$Q = \text{Requivalent}/X_L$$

where: $X_L = 2\pi fL$ and Requivalent is 103 Ω

$$\text{Thus, } Q = 4.65$$

The total system loss is

$$20 \log (103/433) = -12.5 \text{ dB}$$

Quadrature Detector

The quadrature detector is coupled to the IF with an internal 5.0 pF capacitor between Pins 12 and 13. For wideband data applications, the drive to the detector can be increased with an additional external capacitor between these pins; thus, the recovered signal level output is increased for a given bandwidth

The wideband performance of the detector is controlled by the loaded Q of the LC tank circuit. The following equation defines the components which set the detector circuit's bandwidth:

$$Q = R_T/X_L \tag{1}$$

where R_T is the equivalent shunt resistance across the LC Tank

X_L is the reactance of the quadrature inductor at the IF frequency ($X_L = 2\pi fL$).

The inductor and capacitor are chosen to form a resonant LC tank with the PCB and parasitic device capacitance at the desired IF center frequency as predicted by

$$f_c = [2\pi (LC_p)^{1/2}]^{-1} \tag{2}$$

where L is the parallel tank inductor C_p is the equivalent parallel capacitance of the parallel resonant tank circuit.

The following is a design example for a wideband detector at 10.7 MHz and a loaded Q of 18. The loaded Q of the quadrature detector is chosen somewhat less than the Q of the IF bandpass. For an IF frequency of 10.7 MHz and an IF bandpass of 600 kHz, the IF bandpass Q is approximately 6.4.

Example:

Let the external $C_{ext} = 139$ pF. (The minimum value here should be much greater than the internal device and PCB parasitic capacitance, $C_{int} \approx 3.0$ pF). Thus, $C_p = C_{int} + C_{ext} = 142$ pF.

Rewrite equation (2) and solve for L:

$$L = (0.159)^2/(C_p f_c^2)$$

$$L = 1.56 \mu\text{H}; \text{ Thus, a standard value is}$$

chosen:

$$L = 1.56 \mu\text{H (tunable shielded inductor)}$$

The value of the total damping resistor to obtain the required loaded Q of 18 can be calculated by rearranging equation (1):

$$R_T = Q(2\pi fL)$$

$$R_T = 18(2\pi)(10.7)(1.5) = 1815 \Omega$$

The internal resistance, R_{int} at the quadrature tank Pin 13 is approximately 13 k Ω and is considered in determining the external resistance, R_{ext} which is calculated from

$$R_{ext} = ((R_T)(R_{int})) / (R_{int} - R_T)$$

$$R_{ext} = 2110; \text{ Thus, choose the standard value:}$$

$$R_{ext} = 2.2 \text{ k}\Omega$$

It is important to set the DC level of the detector output at Pin 17 to center the peak to peak swing of the recovered signal. In the equivalent internal circuit shown in the Pin Function Description, the reference voltage at the positive terminal of the inverting op amp buffer amplifier is set at 1.0 V_{BE} . The detector DC level, V_{17} is determined by the following equation:

$$V_{17} = [((R_{15}/R_{17}) + 1)/(R_{15}/R_{17})] V_{BE}$$

Thus, for a 1:1 ratio of R_{15}/R_{17} , $V_{17} = 2.0 V_{BE} = 1.4 \text{ Vdc}$. Similarly for a 2:1, $V_{17} = 1.5 V_{BE} = 1.05 \text{ Vdc}$; and for 3:1, $V_{17} = 1.33 V_{BE} = 0.93 \text{ Vdc}$.

Figure 19 shows the detector "S-Curves", in which the resistor ratio is varied while maintaining a constant gain (R_{17} is held at 62 k). R_{15} is 62 k for a 1:1 ratio; while $R_{15} = 120 \text{ k}$ and 180 k to produce the 2:1 and 3:1 ratios. The IF signal into the detector is swept $\pm 500 \text{ kHz}$ about the 10.7 MHz IF center frequency. The resulting curve show how the resistor ratio and the supply voltage effects the symmetry of the "S-curve" (Figure 21 Test Setup). For the 3:1 and 2:1 ratio, symmetry is maintained with V_S from 2.0 to 5.0 Vdc; however, for the 1:1 ratio, symmetry is lost at 2.0 Vdc.

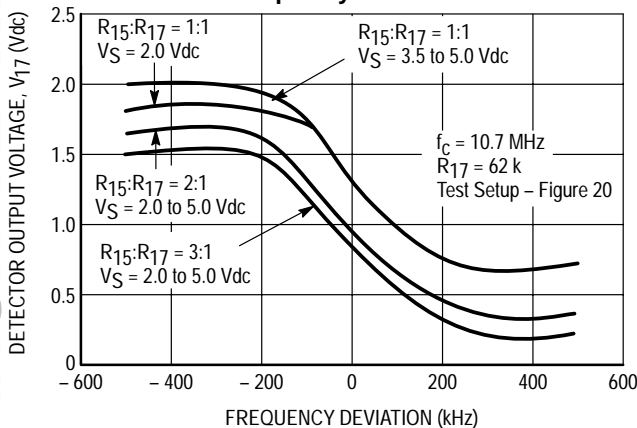

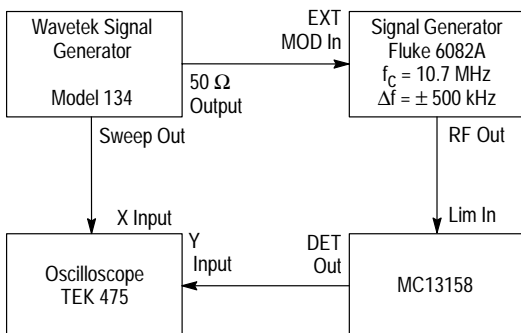

Figure 20. Demodulator "S-Curve" Test Setup

Data Slicer Circuit

C_{20} at the input of the data slicer is chosen to maintain a time constant long enough to hold the charge on the capacitor for the longest strings of bits at the same polarity. For a data rate at 576 kHz a bit stream of 15 bits at the same polarity would equate to an apparent data rate of approximately 77 kbps or 38 kHz. The time constant would be approximately 26 μs . The following expression equates the time constant, t , to the external components:

$$t = 2\pi (R_{18})(C_{20})$$

Solve for C_{20} :

$$C_{20} = t/2\pi (R_{18})$$

where the effective resistance R_{18} is a complex function of the demodulator feedback resistance and the data slicer input circuit. In the data input network the back to back diodes form a charge and discharge path for the capacitor at Pin 20; however, the diodes create a non-linear response. This resistance is loaded by the β , beta of the detector output transistor; beta=100 is a typical value (see Figure 21). Thus, the apparent value of the resistance at Pin 18 (DS IN1) is approximately equal to:

$$R_{18} \sim R_{17}/100$$

where R_{17} is 82 k Ω , the feedback resistor from Pin 17 to 15. Therefore, substituting for R_{18} and solving for C_{20} :

$$C_{20} = 15.9 (t)/R_{17} = 5.04 \text{ nF}$$

The closest standard value is 4.7 nF.

Figure 21. Data Slicer Equivalent Input Circuit

RSSI

In Figure 22, the RSSI versus RF Input Level shows the linear response of RSSI over a 65 dB range but it has extended capability over 80 dB from -80 dBm to +10 dBm. The RSSI is measured in the application circuit (Figure 12) in which a SAW filter is used before the mixer; thus, the overall sensitivity is compromised for the sake of selectivity. The curves are shown for three filters having different bandwidths:

- 1) LCR Filter with 2.3 MHz 3.0 dB BW (Circuit and Component Placement is shown in Figure 12)
- 2) Series-Parallel Ceramic Filter with 650 kHz 3.0 dB BW (Murata Part # KMFC-545)
- 3) Ceramic Filter with 280 kHz 3.0 dB BW.

SINAD Performance

Figure 24 shows a test setup for a narrowband demodulator output response in which a C-message filter and an active de-emphasis filter is used following the demodulator. The input is matched using a 1:4 impedance transformer. The SINAD performance is shown in Figure 25 with no preamp and in Figure 26 with a preamp (Preamp - Figure 16). The 12 dB SINAD sensitivity is -101 dBm with no preamp and -113 dBm with the preamp.
