## PCI-EXPRESS GEN 1, GEN 2, GEN 3, AND GEN 4 FANOUT BUFFER

### Features

- PCI-Express Gen 1, Gen 2, Gen 3, and Gen 4 common clock compliant
- Supports Serial ATA (SATA) at 100 MHz
- 100–210 MHz operation
- Low power, push pull, differential output buffers
- Internal termination for maximum integration
- Dedicated output enable pin for each output
- Six PCI-Express buffered clock outputs
- Clock input spread tolerable
- Supports LVDS outputs
- I<sup>2</sup>C support with readback capabilities
- Extended temperature: –40 to 85 °C
- 3.3 V power supply
- 32-pin QFN package

### Applications

- Network attached storage
- Multi-function printers
- Wireless access point
- Routers

### Description

The Si53156-A13A is a spread spectrum tolerant PCIe clock buffer that can source six PCIe clocks simultaneously. The device has six hardware output enable control inputs for enabling the respective differential outputs on the fly. The device also features output enable control through I<sup>2</sup>C communication. I<sup>2</sup>C programmability is also available to dynamically control skew, edge rate and amplitude on the true, compliment, or both differential signals on the clock outputs. This control feature enables optimal signal integrity as well as optimal EMI signature on the clock outputs. Measuring PCIe clock jitter is quick and easy with the Skyworks Solutions PCIe Clock Jitter Tool. ## 2. Functional Description

### 2.1. OE Pin Definition

The OE pins are active high inputs used to enable and disable the output clocks. To enable the output clock, the OE pin needs to be logic high and the I<sup>2</sup>C output enable bit needs to be logic high. There are two methods to disable the output clocks: the OE is pulled to a logic low, or the I<sup>2</sup>C enable bit is set to a logic low. The OE pins are required to be driven at all times even though they have an internal 100 kΩ resistor.

### 2.2. OE Assertion

The OE signals are active high inputs used for synchronous stopping and starting the DIFF output clocks respectively while the rest of the clock generator continues to function. The assertion of the OE signal by making it logic high causes stopped respective DIFF outputs to resume normal operation. No short or stretched clock pulses are produced when the clock resumes. The maximum latency from the assertion to active outputs is no more than two to six output clock cycles.

### 2.3. OE Deassertion

When the OE pin is deasserted by making it logic low, the corresponding DIFF output is stopped, and the final output state is driven low.

## 3. Test and Measurement Setup

This diagram shows the test load configuration for differential clock signals.

**Figure 1. 0.7 V Differential Load Configuration**

**Figure 2. Differential Measurement for Differential Output Signals (for AC Parameters Measurement)**

**Figure 3. Single-Ended Measurement for Differential Output Signals (for AC Parameters Measurement)**

## 4. Control Registers

### 4.1. I<sup>2</sup>C Interface

To enhance the flexibility and function of the clock buffer, an I<sup>2</sup>C interface is provided. Through the I<sup>2</sup>C Interface, various device functions are available, such as individual clock output enable. The registers associated with the I<sup>2</sup>C Interface initialize to their default setting at power-up. The use of this interface is optional. Clock device register changes are normally made at system initialization, if any are required. Power management functions can only be programmed in program mode and not in normal operation modes.

### 4.2. Data Protocol

The I<sup>2</sup>C protocol accepts byte write, byte read, block write, and block read operations from the controller. For block write/read operation, access the bytes in sequential order from lowest to highest (most significant bit first) with the ability to stop after any complete byte is transferred. For byte write and byte read operations, the system controller can access individually indexed bytes.

The block write and block read protocol is outlined in Table 4 on page 10 while Table 5 on page 11 outlines byte write and byte read protocol. The slave receiver address is 11010110 (D6h).

**Notes:**

**General**

1. All dimensions shown are in millimeters (mm).
2. This Land Pattern Design is based on the IPC-7351 guidelines.

**Solder Mask Design**

1. All metal pads are to be non-solder mask defined (NSMD). Clearance between the solder mask and the metal pad is to be 60  $\mu$ m minimum, all the way around the pad.

**Stencil Design**

1. A stainless steel, laser-cut and electro-polished stencil with trapezoidal walls should be used to assure good solder paste release.
2. The stencil thickness should be 0.125mm (5 mils).
3. The ratio of stencil aperture to land pad size can be 1:1 for all perimeter pads.
4. A 3x3 array of 0.85mm square openings on a 1.00mm pitch can be used for the center ground pad..

**Card Assembly**

1. A No-Clean, Type-3 solder paste is recommended.
2. The recommended card reflow profile is per the JEDEC/IPC J-STD-020 specification for Small Body Components.
